KEPLER-POINSOT SOLID

Kepler's Equation

Kepler's equation gives the relation between the polar coordinates of a celestial body (like a planet) and the time elapsed from a given initial point. Kepler's equation is of fundamental importance in celestial mechanics, but cannot be directly inverted in terms of simple functions in order to determine where the planet will be at a given time.

Let M be the mean anomaly (a parameterization of time) and E the ECCENTRIC ANOMALY (a parameterization of polar angle) of a body orbiting on an ELLIPSE with ECCENTRICITY e, then

$$M = E - e \sin E. \tag{1}$$

For M not a multiple of π, Kepler's equation has a unique solution, but is a TRANSCENDENTAL EQUATION and so cannot be inverted and solved directly for E given an arbitrary M. However, many algorithms have been derived for solving the equation as a result of its importance in celestial mechanics.

Writing a E as a POWER SERIES in e gives

$$E = M + \sum_{n=1}^{\infty} a_n e^n, \tag{2}$$

where the coefficients are given by the LAGRANGE INVERSION THEOREM as

$$a_n = \frac{1}{2^{n-1} n!} \sum_{k=0}^{\lfloor n/2 \rfloor} (-1)^k \binom{n}{k} \times (n-2k)^{n-1} \sin[(n-2k)M] \tag{3}$$

(Wintner 1941, Moulton 1970, Henrici 1974, Finch). Surprisingly, this series diverges for

$$e > 0.6627434193\ldots, \tag{4}$$

a value known as the LAPLACE LIMIT. In fact, E converges as a GEOMETRIC SERIES with ratio

$$r = \frac{e}{1 + \sqrt{1+e^2}} \exp\left(\sqrt{1+e^2}\right) \tag{5}$$

(Finch).

There is also a series solution in BESSEL FUNCTIONS OF THE FIRST KIND,

$$E = M + \sum_{n=1}^{\infty} \frac{2}{n} J_n(ne) \sin(nM). \tag{6}$$

This series converges for all $e < 1$ like a GEOMETRIC SERIES with ratio

$$r = \frac{e}{1 + \sqrt{1-e^2}} \exp\left(\sqrt{1-e^2}\right). \tag{7}$$

The equation can also be solved by letting ψ be the ANGLE between the planet's motion and the direction PERPENDICULAR to the RADIUS VECTOR. Then

$$\tan \psi = \frac{e \sin E}{\sqrt{1-e^2}}. \tag{8}$$

Alternatively, we can define e in terms of an inter-

mediate variable ϕ

$$e \equiv \sin \phi, \tag{9}$$

then

$$\sin\left[\tfrac{1}{2}(v - E)\right] = \sqrt{\frac{r}{p}} \sin\left(\tfrac{1}{2}\phi\right) \sin v \tag{10}$$

$$\sin\left[\tfrac{1}{2}(v + E)\right] = \sqrt{\frac{r}{p}} \cos\left(\tfrac{1}{2}\phi\right) \sin v. \tag{11}$$

Iterative methods such as the simple

$$E_{i+1} = M + e \sin E_i \tag{12}$$

with $E_0 = 0$ work well, as does NEWTON'S METHOD,

$$E_{i+1} = E_i + \frac{M + e \sin E_i - E_i}{1 - e \cos E_i}. \tag{13}$$

In solving Kepler's equation, Stieltjes required the solution to

$$e^x(x - 1) = e^{-x}(x + 1), \tag{14}$$

which is 1.1996678640257734... (Goursat 1959, Le Lionnais 1983).

Kepler-Poinsot Solid

The Kepler-Poinsot solids are the four regular CONCAVE POLYHEDRA with intersecting facial planes. They are composed of regular CONCAVE POLYGONS and were unknown to the ancients. Kepler discovered two and described them in his work *Harmonice Mundi* in 1619. These two were subsequently rediscovered by Poinsot, who also discovered the other two, in 1809. As shown by Cauchy, they are stellated forms of the DODECAHEDRON and ICOSAHEDRON.

The Kepler-Poinsot solids, illustrated above, are known as the GREAT DODECAHEDRON, GREAT ICOSAHEDRON, GREAT STELLATED DODECAHEDRON, and SMALL STELLATED DODECAHEDRON. These names probably originated with Arthur Cayley, who first used them in 1859. Cauchy (1813) proved that these four exhaust all possibilities for regular star polyhedra (Ball and Coxeter 1987).

A table listing these solids, their DUALS, and COMPOUNDS is given below. Like the five Platonic solids, duals of the Kepler-Poinsot solids are themselves Kepler-Poinsot solids (Wenninger 1983, pp. 39 and 43–45).

n	solid	UNIFORM POLYHEDRON	SCHLÄFLI SYMBOL	WYTHOFF SYMBOL	POINT GROUP
1	GREAT DODECAHEDRON	U_{35}	$\left\{5, \frac{5}{2}\right\}$	$\frac{5}{2} \mid 2\,5$	I_h
2	GREAT ICOSAHEDRON	U_{53}	$\left\{3, \frac{5}{2}\right\}$	$3\,\frac{5}{2} \mid \frac{5}{3}$	I_h
3	GREAT STELLATED DODECAHEDRON	U_{52}	$\left\{\frac{5}{2}, 3\right\}$	$3 \mid 2\,\frac{5}{2}$	I_h
4	SMALL STELLATED DODECAHEDRON	U_{34}	$\left\{\frac{5}{2}, 5\right\}$	$5 \mid 2\,\frac{5}{2}$	I_h

The polyhedra $\{\frac{5}{2}, 5\}$ and $\{5, \frac{5}{2}\}$ fail to satisfy the POLYHEDRAL FORMULA

$$V - E + F = 2,$$

where V is the number of vertices, E the number of edges, and F the number of faces, despite the fact that the formula holds for all ordinary polyhedra (Ball and Coxeter 1987). This unexpected result led none less than Schläfli (1860) to erroneously conclude that they could not exist.

In 4-D, there are 10 Kepler-Poinsot solids, and in n-D with $n \geq 5$, there are none. In 4-D, nine of the solids have the same VERTICES as $\{3, 3, 5\}$, and the tenth has the same as $\{5, 3, 3\}$. Their SCHLÄFLI SYMBOLS are $\{\frac{5}{2} 5, 3\}$, $\{3, 5, \frac{5}{2}\}$, $\{5, \frac{5}{2}, 5\}$, $\{\frac{5}{2}, 3, 5\}$, $\{5, 3, \frac{5}{2}\}$, $\{\frac{5}{2}, 5, \frac{5}{2}\}$, $\{5, \frac{5}{2}, 3\}$, $\{3, \frac{5}{2}, 5\}$, $\{\frac{5}{2}, 3, 3\}$, and $\{3, 3, \frac{5}{2}\}$. Coxeter *et al.* (1954) have investigated star "Archimedean" polyhedra.

Ket

A CONTRAVARIANT VECTOR, denoted $|\psi\rangle$. The ket is DUAL to the COVARIANT BRA one-forms $\langle\psi|$. Taken together, the BRA and ket form an ANGLE BRACKET (bra + ket = bracket) $\langle\psi|\psi\rangle$. The ket is commonly encountered in quantum mechanics.

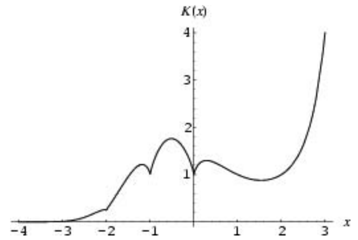
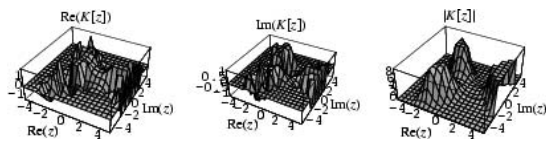
k-Factorable Graph

A GRAPH G is k-factorable if it is the union of disjoint K-FACTORS (Skiena 1990, p. 244).

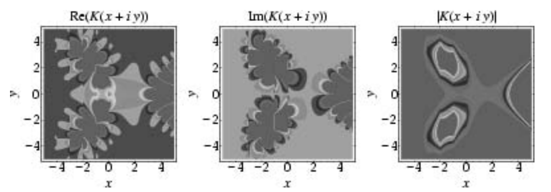
See also K-FACTOR



References



Skiena, S. *Implementing Discrete Mathematics: Combinatorics and Graph Theory with Mathematica.* Reading, MA: Addison-Wesley, 1990.



k-Form

DIFFERENTIAL K-FORM

K-Function

For positive integer n, the K-function is defined by

$$K(n) \equiv 0^0 1^1 2^2 3^3 \cdots (n-1)^{n-1} \tag{1}$$

and is related to the BARNES' G-FUNCTION by

$$K(n) = \frac{[\Gamma(n)]^{n-1}}{G(n)}, \tag{2}$$

where $G(n)$ is defined by

$$G(n) = \begin{cases} 1 & \text{if } n = 0 \\ 0!1!2! \cdots (n-2)! & \text{if } n > 0. \end{cases} \tag{3}$$

The K-function is given by the integral

$$K(z) = (2\pi)^{-(z-1)/2} \exp\left[\binom{z}{2} + \int_0^{z-1} \ln(t!)\, dt\right] \tag{4}$$

and the closed-form expression

$$K(z) = \exp[\zeta'(-1, z) - \zeta'(-1)], \tag{5}$$

where $\zeta(z)$ is the RIEMANN ZETA FUNCTION, $\zeta'(z)$ its DERIVATIVE, $\zeta(a, z)$ is the HURWITZ ZETA FUNCTION, and

$$\zeta'(a, z) \equiv \left[\frac{d\zeta(s, z)}{ds}\right]_{s=a}. \tag{6}$$

$K(z)$ also has a STIRLING-like series

$$K(z+1) = (2^{1/3}\pi_1 z)^{1/12} z^{\binom{z+1}{2}}$$

$$\times \exp\left(\tfrac{1}{4}z^2 + \tfrac{1}{12} - \frac{B_4}{2 \cdot 3 \cdot 4z^2} - \frac{B_6}{4 \cdot 5 \cdot 6z^4} - \ldots\right), \tag{7}$$

where

$$\pi_1 \equiv \left[K\left(\tfrac{1}{2}\right)\right]^8 \tag{8}$$

$$= e^{-(\ln 2)/3 - 12\zeta'(-1)} \tag{9}$$

$$= 2^{2/3}\pi e^{\gamma - 1 - \zeta'(2)/\zeta(2)}, \tag{10}$$

and γ is the EULER-MASCHERONI CONSTANT (Gosper). The first few values of $K(n)$ for $n = 1, 2, \ldots$ are 1, 1, 1, 4, 108, 27648, 86400000, 4031078400000, ... (Sloane's A002109). These numbers are called HYPERFACTORIALS by Sloane and Plouffe (1995).

Khinchin

KHINTCHINE'S CONSTANT

Khinchin Constant

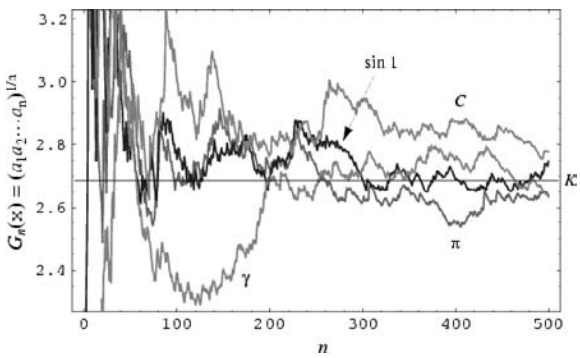
KHINTCHINE'S CONSTANT

Khintchine's Constant

N.B. A detailed online essay by S. Finch was the starting point for this entry.

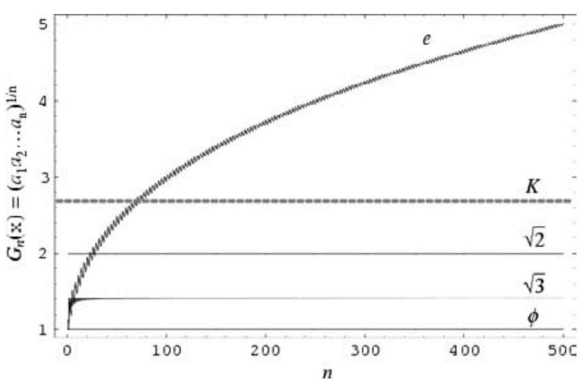
Let

$$x = [a_0, a_1, \ldots] = a_0 + \cfrac{1}{a_1 + \cfrac{1}{a_2 + \cfrac{1}{a_3 + \ldots}}} \tag{1}$$



be the SIMPLE CONTINUED FRACTION of a REAL NUMBER x, where the numbers a_i are the PARTIAL QUOTIENTS. Khintchine (1934) considered the limit of the GEOMETRIC MEAN

$$G_n(x) = (a_1 a_2 \cdots a_n)^{1/n} \tag{2}$$



as $n \to \infty$. Amazingly enough, this limit is a constant *independent* of x–except if x belongs to a set of MEASURE 0-given by

$$K = 2.685452001\ldots \quad (3)$$

(Sloane's A002210), as proved in Kac (1959). The constant is built into *Mathematica* 4.0 as Khinchin.

The values $G_n(x)$ are plotted above for $n = 1$ to 500 and $x = \pi,\ 1/\pi,\ \sin 1$, the EULER-MASCHERONI CONSTANT γ, and the COPELAND-ERDOS CONSTANT. REAL NUMBERS x for which $\lim_{n\to\infty} G_n(x) \neq K$ include $x = e$, $\sqrt{2}$, $\sqrt{3}$, and the GOLDEN RATIO ϕ, plotted below.

The CONTINUED FRACTION for K is [2, 1, 2, 5, 1, 1, 2, 1, 1, ...] (Sloane's A002211; Havermann). It is not known if K is IRRATIONAL, let alone TRANSCENDENTAL. Bailey *et al.* (1995) have computed K to 7350 DIGITS.

Explicit expressions for K include

$$K = \prod_{n=1}^{\infty}\left[1 + \frac{1}{n(n+2)}\right]^{\ln n/\ln 2} \quad (4)$$

$$\ln 2 \ln K = \tfrac{1}{12}\pi^2 + \tfrac{1}{2}(\ln 2)^2 + \int_0^{\pi} \frac{\ln(\theta|\cot\theta|)\,d\theta}{\theta} \quad (5)$$

$$\ln K = \frac{1}{\ln 2}\sum_{m=1}^{\infty}\frac{h_{m-1}}{m}[\zeta(2m) - 1], \quad (6)$$

where $\zeta(z)$ is the RIEMANN ZETA FUNCTION and

$$h_m = \sum_{j=1}^{m}\frac{(-1)^{j-1}}{j} \quad (7)$$

(Shanks and Wrench 1959). Gosper gave

$$\ln K = \frac{1}{\ln 2}\sum_{j=2}^{\infty}\frac{(-1)^j(2-2^j)\zeta'(j)}{j}, \quad (8)$$

where $\zeta'(z)$ is the DERIVATIVE of the RIEMANN ZETA FUNCTION. An extremely rapidly converging sum also due to Gosper is

$$\begin{aligned}\ln K = \frac{1}{\ln 2}\sum_{k=0}^{\infty}\Bigg\{&-\ln(k+1)[\ln(k+3) \\ &-2\ln(k+2) + \ln(k+1)] \\ &-\frac{(-1)^k(2-2^{k+2})}{k+2} \\ &\times\left[\frac{\ln(k+1)}{(k+1)^{k+2}} - \zeta'(k+2,\ k+2)\right] \\ &+\ln(k+1)\left[\sum_{s=1}^{k+2}\frac{(-1)^s(2-2^s)}{(k+1)^s s}\right]\Bigg\},\end{aligned} \quad (9)$$

where $\zeta(s,\ a)$ is the HURWITZ ZETA FUNCTION.

Khintchine's constant is also given by the integral

$$\ln 2 \ln\left(\tfrac{1}{2}K\right) = \int_0^1 \frac{1}{x(1+x)}\ln\left[\frac{\pi x(1-x^2)}{\sin(\pi x)}\right]dx. \quad (10)$$

If P_n/Q_n is the nth CONVERGENT of the CONTINUED FRACTION of x, then

$$\lim_{n\to\infty}(Q_n)^{1/n} = \lim_{n\to\infty}\left(\frac{P_n}{x}\right)^{1/n} = e^{\pi^2/(12\ln 2)} \approx 3.27582 \quad (11)$$

for almost all REAL x (Lévy 1936, Finch). This number is sometimes called the LÉVY CONSTANT, and the argument of the exponential is sometimes called the KHINTCHINE-LÉVY CONSTANT.

Define the following quantity in terms of the kth partial quotient q_k,

$$M(s,\ n,\ x) = \left(\frac{1}{n}\sum_{k=1}^{n} q_k^s\right)^{1/s}. \quad (12)$$

Then

$$\lim_{n\to\infty} M(1,\ n,\ x) = \infty \quad (13)$$

for almost all real x (Khintchine, Knuth 1981, Finch), and

$$M(1,\ n,\ x) \sim \mathcal{O}(\ln n). \quad (14)$$

Furthermore, for $s < 1$, the limiting value

$$\lim_{n\to\infty} M(s, n, x) = K(s) \quad (15)$$

exists and is a constant $K(s)$ with probability 1 (Rockett and Szüsz 1992, Khintchine 1997).

Kiepert's Conics

KIEPERT'S HYPERBOLA, KIEPERT'S PARABOLA

Kiepert's Hyperbola

A curve which is related to the solution of LEMOINE'S PROBLEM and its generalization to ISOSCELES TRIANGLES constructed on the sides of a given TRIANGLE. The VERTICES of the constructed TRIANGLES are

$$A' = -\sin\phi : \sin(C+\phi) : \sin(B+\phi) \quad (1)$$

$$B' = \sin(C+\phi) : -\sin\phi : \sin(A+\phi) \quad (2)$$

$$C' = \sin(B+\phi) : \sin(A+\phi) : -\sin\phi, \quad (3)$$

where ϕ is the base ANGLE of the ISOSCELES TRIANGLE. Kiepert showed that the lines connecting the VERTICES of the given TRIANGLE and the corresponding peaks of the ISOSCELES TRIANGLES CONCUR. The TRILINEAR COORDINATES of the point of concurrence are

$$\sin(B+\phi)\sin(C+\phi) : \sin(C+\phi)\sin(A+\phi) : \sin(A+\phi)\sin(B+\phi). \quad (4)$$

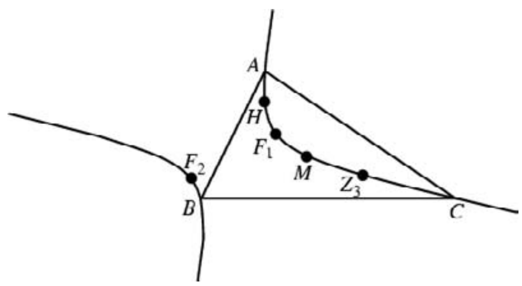
The LOCUS of this point as the base ANGLE varies is given by the curve

$$\frac{\sin(B-C)}{\alpha} + \frac{\sin(C-A)}{\beta} + \frac{\sin(A-B)}{\gamma} = \frac{bc(b^2-c^2)}{\alpha} + \frac{ca(c^2-a^2)}{\beta} + \frac{ab(a^2-b^2)}{\gamma} = 0. \quad (5)$$

Writing the TRILINEAR COORDINATES as

$$\alpha_i = d_i s_i, \quad (6)$$

where d_i is the distance to the side opposite α_i of length s_i and using the POINT-LINE DISTANCE FORMULA with (x_0, y_0) written as (x, y),



$$d_i = \frac{|(y_{i+2} - y_{i+1})(x - x_{i+1})}{s_i} - \frac{(x_{i+2} - x_{i+1})(y - y_{i+1})|}{s_i}, \quad (7)$$

where $y_4 \equiv y_1$ and $y_5 \equiv y_2$ gives the FORMULA

$$\sum_{i=1}^{3} s_{i+1}s_{i+2}(s_{i+1}^2 - s_{i+2}^2)$$
$$\times \frac{s_i}{(y_{i+2} - y_{i+1})(x - x_{i+1}) - (x_{i+2} - x_{i+1})(y - y_{i+1})} = 0 \quad (8)$$

$$\sum_{i=1}^{3} \frac{(s_{i+1}^2 - s_{i+2}^2)}{(y_{i+2} - y_{i+1})(x - x_{i+1}) - (x_{i+2} - x_{i+1})(y - y_{i+1})}$$
$$= 0. \quad (9)$$

Bringing this equation over a common DENOMINATOR then gives a quadratic in x and y, which is a CONIC SECTION (in fact, a HYPERBOLA). The curve can also be written as $\csc(A+t) : \csc(B+t) : \csc(C+t)$, as t varies over $[-\pi/4, \pi/4]$.

Kiepert's hyperbola passes through the triangle's CENTROID M $(\phi = 0)$, ORTHOCENTER H $(\phi = \pi/2)$, VERTICES A $(\phi = -\alpha$ if $\alpha \leq \pi/2$ and $\phi = \pi - \alpha$ if $\alpha > \pi/2)$, B $(\phi = -\beta)$, C $(\phi = -\gamma)$, FERMAT POINTS F_1 $(\phi = \pi/3)$ and F_2 $(\phi = -\pi/3)$, ISOGONAL CONJUGATE of the BROCARD MIDPOINT $(\phi = \omega)$, and BROCARD'S THIRD POINT Z_3 $(\phi = \omega)$, where ω is the BROCARD ANGLE (Eddy and Fritsch 1994, p. 193).

The ASYMPTOTES of Kiepert's hyperbola are the SIMSON LINES of the intersections of the BROCARD AXIS with the CIRCUMCIRCLE. Kiepert's hyperbola is a RECTANGULAR HYPERBOLA. In fact, all nondegenerate conics through the VERTICES and ORTHOCENTER of a TRIANGLE are RECTANGULAR HYPERBOLAS the centers of which lie halfway between the FERMAT POINTS and on the NINE-POINT CIRCLE. The LOCUS of centers of these HYPERBOLAS is the NINE-POINT CIRCLE.

The ISOGONAL CONJUGATE curve of Kiepert's hyperbola is the BROCARD AXIS. The center of the INCIRCLE of the TRIANGLE constructed from the MIDPOINTS of the sides of a given TRIANGLE lies on Kiepert's hyperbola of the original TRIANGLE.

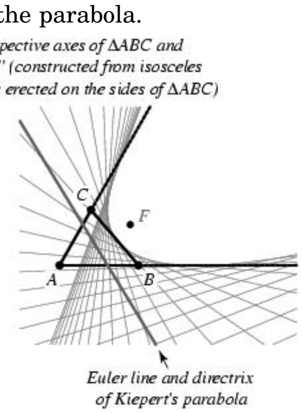
Kiepert's Parabola



Let three similar ISOSCELES TRIANGLES $\Delta A'BC$, $\Delta AB'C$, and $\Delta ABC'$ be constructed on the sides of a TRIANGLE ΔABC. Then ΔABC and $\Delta A'B'C''$ are PERSPECTIVE TRIANGLES, and the ENVELOPE of their PERSPECTIVE AXIS as the vertex angle of the erected triangles is varied is a PARABOLA known as Kiepert's parabola. It has equation

$$\frac{\sin A(\sin^2 B - \sin^2 C)}{u} + \frac{\sin B(\sin^2 C - \sin^2 A)}{v}$$
$$+ \frac{\sin C(\sin^2 A - \sin^2 B)}{w} = 0 \quad (1)$$

$$\frac{a(b^2 - c^2)}{u} + \frac{b(c^2 - a^2)}{v} + \frac{c(a^2 - b^2)}{w} = 0, \quad (2)$$

where $[u, v, w]$ are the TRILINEAR COORDINATES for a line tangent to the parabola.

Kiepert's parabola is tangent to the sides of the TRIANGLE (or their extensions), the line at infinity, and the LEMOINE LINE. The FOCUS has TRIANGLE CENTER FUNCTION

$$\alpha = \csc(B - C). \quad (3)$$

The EULER LINE of a triangle is the DIRECTRIX of Kiepert's parabola. In fact, the DIRECTRICES of all parabolas inscribed in a TRIANGLE pass through the ORTHOCENTER. The BRIANCHON POINT for Kiepert's parabola is the STEINER POINT of ΔABC.

See also BRIANCHON POINT, ENVELOPE, EULER LINE, ISOSCELES TRIANGLE, LEMOINE LINE, PARABOLA, STEINER POINTS

Kieroid

Let the center B of a CIRCLE of RADIUS a move along a line BA. Let O be a fixed point located a distance c away from AB. Draw a SECANT LINE through O and D, the MIDPOINT of the chord cut from the line DE (which is parallel to AB) and a distance b away. Then the LOCUS of the points of intersection of OD and the CIRCLE P_1 and P_2 is called a kieroid.

Special Case	Curve
$b = 0$	CONCHOID OF NICOMEDES
$b = a$	CISSOID plus asymptote
$b = a = -c$	STROPHOID plus ASYMPTOTE

Killing Form

The Killing form is an INNER PRODUCT on a finite dimensional LIE ALGEBRA $\mathfrak{g}$ defined by

$$B(X,\ Y) = \mathrm{Tr}(\mathrm{ad})(X)\ \mathrm{ad}(Y)) \quad (1)$$

in the ADJOINT REPRESENTATION, where ad(X) is the adjoint representation of X. (1) is adjoint-invariant in the sense that

$$B(\mathrm{ad}(X)Y,\ Z) = -B(Y,\ \mathrm{ad}(X)Z). \quad (2)$$

When $\mathfrak{g}$ is a SEMISIMPLE LIE ALGEBRA, the Killing form is NONDEGENERATE.

For example, the SPECIAL LINEAR LIE ALGEBRA $\mathfrak{sl}_2(\mathbb{C})$ has three basis vectors $\{X,\ Y,\ H\}$, where $[X,\ Y] = 2H$:

$$X = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \quad (3)$$

$$Y = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix} \quad (4)$$

$$H = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}. \quad (5)$$

The other brackets are given by $[X,\ H] = 2Y$ and $[Y,\ H] = 2X$. In the adjoint representation, with the ordered basis $\{X,\ Y,\ H\}$, these elements are represented by

$$\mathrm{ad}(X) = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 2 \\ 0 & 2 & 0 \end{bmatrix} \quad (6)$$

$$\mathrm{ad}(Y) = \begin{bmatrix} 0 & 0 & 2 \\ 0 & 0 & 0 \\ -2 & 0 & 0 \end{bmatrix} \quad (7)$$

$$\mathrm{ad}(H) = \begin{bmatrix} 0 & -2 & 0 \\ -2 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \quad (8)$$

and so $B(u, v) = u^{\mathrm{T}} B v$ where

$$B = \begin{bmatrix} 8 & 0 & 0 \\ 0 & -8 & 0 \\ 0 & 0 & 8 \end{bmatrix}. \quad (9)$$

Killing Vectors

If any set of points is displaced by $X^i\ dx_i$ where all distance relationships are unchanged (i.e., there is an ISOMETRY), then the VECTOR FIELD is called a Killing vector.

$$g_{ab} = \frac{\partial x'^c}{\partial x^a} \frac{\partial x'^d}{\partial x^b} g_{cd}(x'), \quad (1)$$

so let

$$x'^a = x^a + \epsilon x^a \quad (2)$$

$$\frac{\partial x'^a}{\partial x^b} = \delta^a_b + \epsilon x^a{}_{,b} \quad (3)$$

$$g_{ab}(x) = (\delta^c_a + \epsilon x^c{}_{,a})(\delta^d_b + \epsilon x^d{}_{,b}) g_{cd}(x^e + \epsilon X^e)$$
$$= (\delta^c_a + \epsilon x^c{}_{,a})(\delta^d_b + \epsilon x^d{}_{,b})[g_{cd}(x) + \epsilon X^e g_{cd}(x)_{,e} + \ldots]$$

$$= g_{ab}(x) + \epsilon[g_{ad}X^d{}_{,b} + g_{bd}X^d{}_{,a} + X^e g_{ab,e}] + \mathcal{O}(\epsilon^2)$$

$$= g_{ab} + \mathcal{L}_X g_{ab}$$

$$= g'_{ab}, \tag{4}$$

where $\mathcal{L}$ is the LIE DERIVATIVE.

An ordinary derivative can be replaced with a COVARIANT DERIVATIVE in a LIE DERIVATIVE, so we can take as the definition

$$g_{ab;\ c=0} \tag{5}$$

$$g_{ab}g^{bc} = \delta^c_a, \tag{6}$$

which gives KILLING'S EQUATION

$$\mathcal{L}_X g_{ab} = X_{a;\ b} + X_{b;\ a} = 2X_{(a;\ b)} = 0, \tag{7}$$

where $X_{(a;\ b)}$ denotes the SYMMETRIC TENSOR part and $X_{a;\ b}$ is a COVARIANT DERIVATIVE.

A Killing vector X^b satisfies

$$g^{bc}X_{c;\ ab} - R_{ab}X^b = 0 \tag{8}$$

$$X_{a;\ bc} = R_{abcd}X^d \tag{9}$$

$$X^{a;\ b}{}_{;b} + R^a_c X^c = 0, \tag{10}$$

where R_{ab} is the RICCI TENSOR and R_{abcd} is the RIEMANN TENSOR.

A 2-sphere with METRIC

$$ds^2 = d\theta^2 + \sin^2\theta\, d\phi^2 \tag{11}$$

has three Killing vectors, given by the angular momentum operators

$$\tilde{L}_x = -\cos\phi \frac{\partial}{\partial\theta} + \cot\theta\sin\phi \frac{\partial}{\partial\phi} \tag{12}$$

$$\tilde{L}_y = \sin\phi \frac{\partial}{\partial\theta} + \cot\theta\cos\phi \frac{\partial}{\partial\phi} \tag{13}$$

$$\tilde{L}_z = \frac{\partial}{\partial\phi}. \tag{14}$$

The Killing vectors in Euclidean 3-space are

$$x^1 = \frac{\partial}{\partial x} \tag{15}$$

$$x^2 = \frac{\partial}{\partial y} \tag{16}$$

$$x^3 = \frac{\partial}{\partial z} \tag{17}$$

$$x^4 = y\frac{\partial}{\partial z} - z\frac{\partial}{\partial y} \tag{18}$$

$$x^5 = z\frac{\partial}{\partial x} - x\frac{\partial}{\partial z} \tag{19}$$

$$x^6 = x\frac{\partial}{\partial y} - y\frac{\partial}{\partial x}. \tag{20}$$

In MINKOWSKI SPACE, there are 10 Killing vectors

$$X^\mu_i = a^\mu_i \quad \text{for } i = 1, 2, 3, 4 \tag{21}$$

$$X^0_k = 0 \tag{22}$$

$$X^l_k = \epsilon^{lkm}x_m \quad \text{for } k = 1, 2, 3 \tag{23}$$

$$X^k_\mu = \delta_\mu^{[0_z k]} \quad \text{for } k = 1, 2, 3. \tag{24}$$

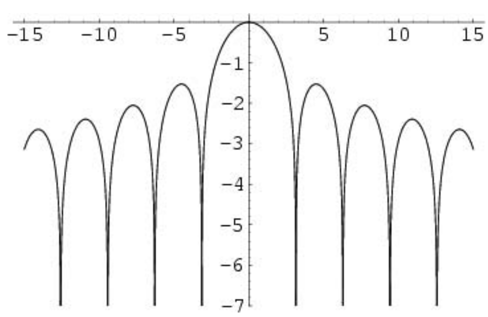
The first group is TRANSLATION, the second ROTATION, and the final corresponds to a "boost. "

See also KILLING'S EQUATION, LIE DERIVATIVE

Killing's Equation

The equation defining KILLING VECTORS.

$$\mathcal{L}_X g_{ab} = X_{a;\ b} + X_{b;\ a} = 2X_{(a;\ b)} = 0,$$



where $\mathcal{L}$ is the LIE DERIVATIVE and $X_{b;\ a}$ is a COVARIANT DERIVATIVE.

See also KILLING VECTORS, LIE DERIVATIVE

Kilroy Curve

The curve defined by the Cartesian equation

$$f(x) = \ln\left|\frac{\sin x}{x}\right| = \ln|\text{sinc}\, x|.$$

The Kilroy curve arises in the study of spread spectra plotted on a logarithmic (decibel) scale, and is so named because it resembles Kilroy looking over a wall.

See also SINC FUNCTION

Kimberling Sequence

A sequence generated by beginning with the POSITIVE INTEGERS, then iteratively applying the following algorithm:

1. In iteration i, discard the ith element,
2. Alternately write the $i+k$ and $i-k$th elements until $k=i$,
3. Write the remaining elements in order.

The first few iterations are therefore

$\boxed{1}$	2	3	4	5	6	7	8	9	10	11
2	$\boxed{3}$	4	5	6	7	8	9	10	11	12
4	2	$\boxed{5}$	6	7	8	9	10	11	12	13.
6	2	7	$\boxed{4}$	8	9	10	11	12	13	14
8	7	9	2	$\boxed{10}$	6	11	12	13	14	15

The diagonal elements form the sequence 1, 3, 5, 4, 10, 7, 15, ... (Sloane's A007063).

Kimberling Shuffle

KIMBERLING SEQUENCE

King Walk

DELANNOY NUMBER

Kings Problem

Kg		Kg		Kg		Kg	
Kg		Kg		Kg		Kg	
Kg		Kg		Kg		Kg	
Kg		Kg		Kg		Kg	

The problem of determining how many nonattacking kings can be placed on an $n \times n$ CHESSBOARD. For $n=8$, the solution is 16, as illustrated above (Madachy 1979). In general, the solutions are

$$K(n) = \begin{cases} \frac{1}{4}n^2 & n \text{ even} \\ \frac{1}{4}(n+1)^2 & n \text{ odd} \end{cases} \tag{1}$$

(Madachy 1979), giving the sequence of doubled squares 1, 1, 4, 4, 9, 9, 16, 16, ... (Sloane's A008794). This sequence has GENERATING FUNCTION

$$\frac{1+x^2}{(1-x^2)^2(1-x)} = 1 + x + 4x^2 + 4x^3 + 9x^4 + 9x^5 + \ldots. \tag{2}$$

Kg			Kg			Kg	
Kg			Kg			Kg	
Kg			Kg			Kg	

The minimum number of kings needed to attack or occupy all squares on an 8×8 CHESSBOARD is nine, illustrated above (Madachy 1979).

Kirkman Triple System

A Kirkman triple system of order $v=6n+3$ is a STEINER TRIPLE SYSTEM with parallelism (Ball and Coxeter 1987), i.e., one with the following additional stipulation: the set of $b=(2n+1)(3n+1)$ triples is partitioned into $(3n+1)$ components such that each component is a $(2n+1)$-subset of triples and each of the v elements appears exactly once in each component. The STEINER TRIPLE SYSTEMS of order 3 and 9 are Kirkman triple systems with $n=0$ and 1. Solution to KIRKMAN'S SCHOOLGIRL PROBLEM requires construction of a Kirkman triple system of order $n=2$.

Ray-Chaudhuri and Wilson (1971) showed that there exists at least one Kirkman triple system for every NONNEGATIVE order n. Earlier editions of Ball and Coxeter (1987) gave constructions of Kirkman triple systems with $9 \le v < 99$. For $n=1$, there is a single unique (up to an isomorphism) solution, while there are 7 different systems for $n=2$ (Mulder 1917, Cole 1922, Ball and Coxeter 1987).

Kirkman's Schoolgirl Problem

In a boarding school there are fifteen schoolgirls who always take their daily walks in rows of threes. How can it be arranged so that each schoolgirl walks in the same row with every other schoolgirl exactly once a week? Solution of this problem is equivalent to constructing a KIRKMAN TRIPLE SYSTEM of order $n=2$. The following table gives one of the 7 distinct (up to permutations of letters) solutions to the problem.

Sun	Mon	Tue	Wed	Thu	Fri	Sat
ABC	ADE	AFG	AHI	AJK	ALM	ANO
DHL	BIK	BHJ	BEG	CDF	BEF	BDG

EJN	CMO	CLN	CMN	BLO	CIJ	CHK
FIO	FHN	DIM	DJO	EHM	DKN	EIL
GKM	GJL	EKO	FKL	GIN	GHO	FJM

(The table of Dörrie 1965 contains four omissions in which the $a_1 = B$ and $a_2 = C$ entries for Wednesday and Thursday are written simply as a.)

Kissing Circles Problem

Descartes Circle Theorem, Soddy Circles

Kissing Number

The number of equivalent hyperspheres in n-D which can touch an equivalent hypersphere without any intersections, also sometimes called the Newton number, contact number, coordination number, or ligancy. Newton correctly believed that the kissing number in 3-D was 12, but the first proofs were not produced until the 19th century (Conway and Sloane 1993, p. 21) by Bender (1874), Hoppe (1874), and Günther (1875). More concise proofs were published by Schütte and van der Waerden (1953) and Leech (1956). After packing 12 spheres around the central one (which can be done, for example, by arranging the spheres so that their points of tangency with the central sphere correspond to the vertices of an icosahedron), there is a significant amount of free space left (above figure), although not enough to fit a 13th sphere.

Exact values for *lattice packings* are known for $n = 1$ to 9 and $n = 24$ (Conway and Sloane 1992, Sloane and Nebe). Odlyzko and Sloane (1979) found the exact value for 24-D.

The arrangement of n points on the surface of a sphere, corresponding to the placement of n identical spheres around a central sphere (not necessarily of the same radius) is called a spherical packing.

The following table gives the largest known kissing numbers in dimension D for lattice (L) and nonlattice (NL) packings (if a nonlattice packing with higher number exists). In nonlattice packings, the kissing number may vary from sphere to sphere, so the largest value is given below (Conway and Sloane 1993, p. 15). A more extensive and up-to-date tabulation is maintained by Sloane and Nebe.

D	L	NL	D	L	NL
1	2		13	≥ 918	$\geq 1{,}130$

2	6		14	$\geq 1{,}422$	$\geq 1{,}582$
3	12		15	$\geq 2{,}340$	
4	24		16	$\geq 4{,}320$	
5	40		17	$\geq 5{,}346$	
6	72		18	$\geq 7{,}398$	
7	126		19	$\geq 10{,}668$	
8	240		20	$\geq 17{,}400$	
9	272	≥ 306	21	$\geq 27{,}720$	
10	≥ 336	≥ 500	22	$\geq 49{,}896$	
11	≥ 438	≥ 582	23	$\geq 93{,}150$	
12	≥ 756	≥ 840	24	196,560	

The lattices having maximal packing numbers in 12- and 24-D have special names: the COXETER-TODD LATTICE and LEECH LATTICE, respectively. The general form of the lower bound of n-D lattice densities given by

$$\eta \geq \frac{\zeta(n)}{2^{n-1}},$$

where $\zeta(n)$ is the RIEMANN ZETA FUNCTION, is known as the MINKOWSKI-HLAWKA THEOREM.

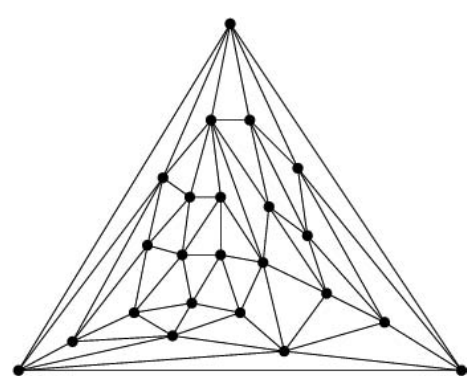
Kite

A planar convex QUADRILATERAL consisting of two adjacent sides of length a and the other two sides of length b. The RHOMBUS is a special case of the kite, and the LOZENGE is a special case of the RHOMBUS. The AREA of a kite is given by

$$A = \tfrac{1}{2} pq,$$



where p and q are the lengths of the DIAGONALS, which are PERPENDICULAR.

Klein Bottle

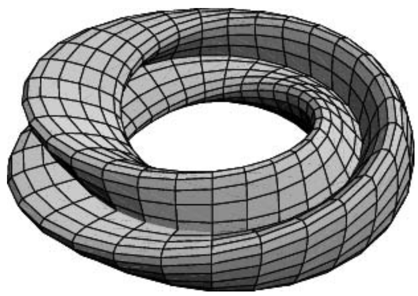
Klein bottle

A closed NONORIENTABLE SURFACE of EULER CHARACTERISTIC 0 (Dodson and Parker 1997, p. 125) that has no inside or outside. It can be constructed by gluing both pairs of opposite edges of a RECTANGLE together giving one pair a half-twist, but can be physically realized only in 4-D, since it must pass through itself without the presence of a HOLE. Its TOPOLOGY is equivalent to a pair of CROSS-CAPS with coinciding boundaries (Francis and Weeks 1999). It can be cut in half along its length to make two MÖBIUS STRIPS (Dodson and Parker 1997, p. 88), but can also be cut into a *single* MÖBIUS STRIP (Gardner 1984, pp. 14 and 17).

The above picture is an IMMERSION of the Klein bottle in $\mathbb{R}^3$ (3-space). There is also another possible IMMERSION called the "figure-8" IMMERSION (Geometry Center).

The equation for the usual IMMERSION is given by the implicit equation

$$(x^2+y^2+z^2+2y-1)[(x^2+y^2+z^2+2y-1)^2-8z^2]$$



$$+16xz(x^2+y^2+z^2-2y-1)=0 \quad (1)$$

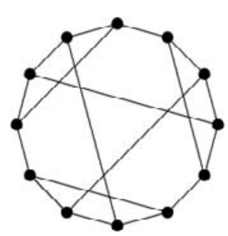
(Stewart 1991). Nordstrand gives the parametric form

$$x = \cos u\left[\cos\left(\tfrac{1}{2}u\right)\left(\sqrt{2}+\cos v\right)+\sin\left(\tfrac{1}{2}u\right)\sin v\cos v\right] \quad (2)$$

$$y = \sin u\left[\cos\left(\tfrac{1}{2}u\right)\left(\sqrt{2}+\cos v\right)+\sin\left(\tfrac{1}{2}u\right)\sin v\cos v\right] \quad (3)$$

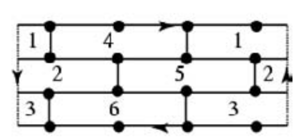
$$z = -\sin\left(\tfrac{1}{2}u\right)\left(\sqrt{2}+\cos v\right)+\cos\left(\tfrac{1}{2}u\right)\sin v\cos v. \quad (4)$$

The "figure-8" form of the Klein bottle is obtained by rotating a figure eight about an axis while placing a twist in it, and is given by PARAMETRIC EQUATIONS



$$x(u,\ v) = \left[a + \cos\left(\tfrac{1}{2}u\right)\ \sin(v) - \sin\left(\tfrac{1}{2}u\right)\ \sin(2v)\right]\cos(u) \quad (5)$$

$$y(u,\ v) = \left[a + \cos\left(\tfrac{1}{2}u\right)\ \sin(v) - \sin\left(\tfrac{1}{2}u\right)\ \sin(2v)\right]\ \sin(u) \quad (6)$$



$$z(u,\ v) = \sin\left(\tfrac{1}{2}u\right)\ \sin(v) + \cos\left(\tfrac{1}{2}u\right)\ \sin(2v) \quad (7)$$

for $u \in [0,\ 2\pi)$, $v \in [0,\ 2\pi)$, and $a > 2$ (Gray 1997).

The image of the CROSS-CAP map of a TORUS centered at the ORIGIN is a Klein bottle (Gray 1997, p. 339). The MÖBIUS SHORTS are topologically equivalent to a Klein bottle with a hole (Gramain 1984, Stewart 2000).

Franklin graph

coloring of the Klein bottle

Any set of regions on the Klein bottle can be colored using six colors only (Franklin 1934, Saaty and Kainen 1986), providing the sole exception to the HEAWOOD CONJECTURE (Bondy and Murty 1976, p. 244).

Klein Bottle Dissection

Every MÖBIUS STRIP DISSECTION of unequal squares can be glued along its edge to produce a dissection of the Klein bottle. There are no other ways to tile a Klein bottle with six or fewer squares, the situation is unknown for seven or eight squares, but it is known that other types of dissections do exists for nine squares (Stewart 1997).

Klein's Absolute Invariant

Let ω_1 and ω_2 be periods of a DOUBLY PERIODIC FUNCTION, with $\tau = \omega_2/\omega_1$ the HALF-PERIOD RATIO a number with $\Im[\tau] \neq 0$. Then Klein's absolute invariant (also called Klein's modular function) is defined as

$$J(\omega_1,\ \omega_2) \equiv \frac{g_2^3(\omega_1,\ \omega_2)}{\Delta(\omega_1,\ \omega_2)}, \tag{1}$$

where g_2 and g_3 are the invariants of the WEIERSTRASS ELLIPTIC FUNCTION with MODULAR DISCRIMINANT

$$\Delta \equiv g_2^3 - 27g_3^2 \tag{2}$$

(Klein 1877). If $\tau \in H$, where H is the UPPER HALF-PLANE, then

$$J(\tau) \equiv J(1,\ \tau) = J(\omega_1,\ \omega_2) \tag{3}$$

is a function of the ratio τ only, as are g_2, g_3, and Δ. Furthermore, $g_2(\tau)$, $g_3(\tau)$, $\Delta(\tau)$, and $J(\tau)$ are analytic in H (Apostol 1997, p. 15).

$J(\tau)$ is invariant under a UNIMODULAR TRANSFORMATION, so

$$J\left(\frac{a\tau + b}{c\tau + d}\right) = J(\tau), \tag{4}$$

and $J(\tau)$ is a MODULAR FUNCTION. $J(\tau)$ takes on the special values

$$J(\rho = e^{2\pi i/3}) = 0 \tag{5}$$

$$J(i) = 1 \tag{6}$$

$$J(i\infty) = \infty. \tag{7}$$

Every RATIONAL FUNCTION of J is a MODULAR FUNCTION, and every MODULAR FUNCTION can be expressed as a RATIONAL FUNCTION of J (Apostol 1997, p. 40). The FOURIER SERIES of $J(\tau)$, modulo a constant multiplicative factor, is called the j-FUNCTION.

Klein's invariant can be given explicitly by

$$J(q) \equiv \frac{4}{27}\frac{[1 - \lambda(q) + \lambda^2(q)]^3}{\lambda^2(q)[1 - \lambda(q)]^2} = \frac{[E_4(q)]^3}{[E_4(q)]^3 - [E_6(q)]^2} \tag{8}$$

(Klein 1878/79, Cohn 1994), where $q \equiv e^{i\pi t}$ is the NOME, $\lambda(q)$ is the ELLIPTIC LAMBDA FUNCTION

$$\lambda(q) \equiv k^2(q) = \left[\frac{\vartheta_2(q)}{\vartheta_3(q)}\right]^4, \tag{9}$$

$\vartheta_i(q)$ is a JACOBI THETA FUNCTION, and the $E_i(q)$ are RAMANUJAN-EISENSTEIN SERIES.

Klein's Equation

If a real ALGEBRAIC CURVE has no singularities except nodes and CUSPS, BITANGENTS, and INFLECTION POINTS, then

$$n + 2\tau_2' + \iota' = m + 2\delta_2' + \kappa',$$

where n is the order, τ' is the number of conjugate tangents, ι' is the number of REAL inflections, m is the class, δ' is the number of REAL conjugate points, and κ' is the number of REAL CUSPS. This is also called KLEIN'S THEOREM.

KLEIN'S ABSOLUTE INVARIANT

Klein's Theorem

KLEIN'S EQUATION

Klein-Beltrami Model

The Klein-Beltrami model of HYPERBOLIC GEOMETRY consists of an OPEN DISK in the Euclidean plane whose open chords correspond to hyperbolic lines. Two lines l and m are then considered parallel if their chords fail to intersect and are PERPENDICULAR under the following conditions,

1. If at least one of l and m is a diameter of the DISK, they are hyperbolically perpendicular IFF they are perpendicular in the Euclidean sense.
2. If neither is a diameter, l is perpendicular to m IFF the Euclidean line extending l passes through the pole of m (defined as the point of intersection of the tangents to the disk at the "endpoints" of m).

There is an isomorphism between the POINCARÉ HYPERBOLIC DISK model and the Klein-Beltrami model. Consider a Klein disk in Euclidean 3-space with a SPHERE of the same radius seated atop it, tangent at the ORIGIN. If we now project chords on the disk orthogonally upward onto the SPHERE's lower HEMISPHERE, they become arcs of CIRCLES orthogonal to the equator. If we then stereographically project the SPHERE's lower HEMISPHERE back onto the plane of the Klein disk from the north pole, the equator will map onto a disk somewhat larger than the Klein disk, and the chords of the original Klein disk will now be arcs of CIRCLES orthogonal to this larger disk. That is, they will be Poincaré lines. Now we can say that two Klein lines or angles are congruent IFF their corresponding Poincaré lines and angles under this isomorphism are congruent in the sense of the Poincaré model.

KleinInvariantJ

KLEIN'S ABSOLUTE INVARIANT

Kloosterman's Sum

$$S(u,\ v,\ n)\equiv\sum_n \exp\left[\frac{2\pi i(uh+v\bar{h})}{n}\right], \tag{1}$$

where h runs through a complete set of residues RELATIVELY PRIME to n, and $\bar{h}$ is defined by

$$h\bar{h}\equiv 1\ (\text{mod } n). \tag{2}$$

If $(n, n)=1$ (if n and (n') are RELATIVELY PRIME), then

$$S(u, v, n)S(u, v', n') = S(u, vn'^2 + v'n^2, nn'). \quad (3)$$

Kloosterman's sum essentially solves the problem introduced by Ramanujan of representing sufficiently large numbers by QUADRATIC FORMS $ax_1^2 + bx_2^2 + cx_3^2 + dx_4^2$. Weil improved on Kloosterman's estimate for Ramanujan's problem with the best possible estimate

$$|S(u, v, n)| \leq 2\sqrt{n} \quad (4)$$

(Duke 1997).

k-Matrix

A k-matrix is a kind of CUBE ROOT of the IDENTITY MATRIX (distinct from the IDENTITY MATRIX) which is defined by the COMPLEX MATRIX

$$\mathsf{k} = \begin{bmatrix} 0 & 0 & -i \\ i & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}.$$

It satisfies

$$\mathsf{k}^3 = \mathsf{I}$$

where I is the IDENTITY MATRIX.

See also COMPLEX MATRIX, CUBE ROOT, IDENTITY MATRIX, QUATERNION

K-Means Clustering Algorithm

An algorithm for partitioning (or clustering) N data points into K disjoint subsets $\mathcal{S}_j$ containing N_j data points so as to minimize the sum-of-squares criterion

$$J = \sum_{j=1}^{K} \sum_{n \in \mathcal{S}_j} ||x_n - \mu_j||^2,$$

where x_n is a vector representing the nth data point and μ_j is the CENTROID of the data points in $\mathcal{S}_j$. In general, the algorithm does not achieve a GLOBAL MINIMUM of J over the assignments. In fact, since the algorithm uses discrete assignment rather than a set of continuous parameters, the "minimum" it reaches cannot even be properly called a LOCAL MINIMUM. Despite these limitations, the algorithm is used fairly frequently as a result of its ease of implementation.

The algorithm consists of a simple re-estimation procedure as follows. First, the data points are assigned at random to the K sets. Then the centroid is computed for each set. These two steps are alternated until a stopping criterion is met, i.e., when there is no further change in the assignment of the data points.

Knapsack Problem

Given a SUM and a set of WEIGHTS, find the WEIGHTS which were used to generate the SUM. The values of the weights are then encrypted in the sum. This system relies on the existence of a class of knapsack problems which can be solved trivially (those in which the weights are separated such that they can be "peeled off" one at a time using a GREEDY-like algorithm), and transformations which convert the trivial problem to a difficult one and vice versa. Modular multiplication is used as the TRAPDOOR ONE-WAY FUNCTION. The simple knapsack system was broken by Shamir in 1982, the Graham-Shamir system by Adleman, and the iterated knapsack by Ernie Brickell in 1984.

Knight's Tour

A knight's tour of a CHESSBOARD (or any other grid) is a sequence of moves by a knight CHESS piece (which may only make moves which simultaneously shift one square along one axis and two along the other) such that each square of the board is visited exactly once (i.e., a HAMILTONIAN CIRCUIT). If the final position is a knight's move away from the first position, the tour is called re-entrant. The above figures shows six knight's tours on an 8×8 CHESSBOARD, all but the first of which are re-entrant. The final tour has the additional property that it is a SEMIMAGIC SQUARE with row and column sums of 260 and main diagonal sums of 348 and 168 (Steinhaus 1983, p. 30).

BACKTRACKING algorithms (in which the knight is allowed to move as far as possible until it comes to a blind alley, at which point it backs up some number of steps and then tries a different path) can be used to find knight's tours, but such methods can be very slow. Warnsdorff (1823) proposed an algorithm that finds a path without any backtracking by computing ratings for "successor" steps at each position. Here, successors of a position are those squares that have not yet been visited and can be reached by a single move from the given position. The rating is highest for the successor whose number of successors is least. In this way, squares tending to be isolated are visited first and therefore prevented from being isolated (Roth). The time needed for this algorithm grows roughly linearly with the number of squares of the chessboard, but unfortunately computer implementation show that this algorithm runs into blind alleys for chessboards bigger than 76×76, despite the fact that it works well on smaller boards (Roth).

Recently, Conrad *et al.* (1994) discovered another linear time algorithm and proved that it solves the problem for all $n \geq 5$. The Conrad *et al.* algorithm works by decomposition of the chessboard into smaller chessboards (not necessarily square) for which explicit solutions are known. This algorithm is rather complicated because it has to deal with many special cases, but has been implemented in *Mathematica* by A. Roth. Example tours are illustrated above for $n \times n$ boards with $n = 5$ to 8.

Löbbing and Wegener (1996) computed the number of cycles covering the directed knight's graph for an 8×8 CHESSBOARD. They obtained α^2, where $\alpha = 2{,}849{,}759{,}680$, i.e., 8,121,130,233,753,702,400. They also computed the number of undirected tours, obtaining an incorrect answer 33,439,123,484,294 (which is not divisible by 4 as it must be), and so are currently redoing the calculation.

The following results are given by Kraitchik (1942). The number of possible tours on a $4k \times 4k$ board for $k = 3, 4, \ldots$ are 8, 0, 82, 744, 6378, 31088, 189688, 1213112, ... (Kraitchik 1942, p. 263). There are 14 tours on the 3×7 rectangle, two of which are symmetrical. There are 376 tours on the 3×8 rectangle, none of which is closed. There are 16 symmetric tours on the 3×9 rectangle and 8 closed tours on the 3×10 rectangle. There are 58 symmetric tours on the 3×11 rectangle and 28 closed tours on the 3×12 rectangle. There are five doubly symmetric tours on the 6×6 square. There are 1728 tours on the 5×5 square, 8 of which are symmetric. The longest "uncrossed" knight's tours on an $n \times n$ board for $n = 3, 4, \ldots$ are 2, 5, 10, 17, 24, 35, ... (Sloane's A003192).

The problem of determining how many nonattacking knights $K(n)$ can be placed on an $n \times n$ CHESSBOARD. For $n = 8$, the solution is 32 (illustrated above). In general, the solutions are

$$K(n) = \begin{cases} \frac{1}{2}n^2 & n > 2 \text{ even} \\ \frac{1}{2}(n^2+1) & n > 1 \text{ odd}, \end{cases}$$

giving the sequence 1, 4, 5, 8, 13, 18, 25, ... (Sloane's A030978, Dudeney 1970, p. 96; Madachy 1979).

Knödel Numbers

For every $k \geq 1$, let C_k be the set of COMPOSITE NUMBERS $n > k$ such that if $1 < a < n$, $\text{GCD}(a, n) = 1$ (where GCD is the GREATEST COMMON DIVISOR), then $a^{n-k} \equiv 1 \pmod{n}$. C_1 is the set of CARMICHAEL NUMBERS. Makowski (1962/1963) proved that there are infinitely many members of C_k for $k \geq 2$.

Knot

A knot is defined as a closed, non-self-intersecting curve embedded in 3-D. A knot is a single component LINK. Knot theory was given its first impetus when Lord Kelvin proposed a theory that atoms were vortex loops, with different chemical elements consisting of different knotted configurations (Thompson 1867). P. G. Tait then cataloged possible knots by trial and error. Much progress has been made in the intervening years.

Klein proved that knots cannot exist in an EVEN-numbered dimensional space ≥ 4. It has since been shown that a knot cannot exist in *any* dimension ≥ 4. Two distinct knots cannot have the same KNOT COMPLEMENT (Gordon and Luecke 1989), but two LINKS can! (Adams 1994, p. 261). Schubert (1949) showed that every knot can be uniquely decomposed (up to the order in which the decomposition is performed) as a KNOT SUM of a class of knots known as PRIME KNOTS, which cannot themselves be further decomposed. Combining PRIME KNOTS gives no new knot types for knots of three to five crossing, but one additional COMPOSITE KNOT each for knots of six and seven crossings.

Knots are most commonly cataloged based on the minimum number of crossings present (the so-called CROSSING NUMBER. Thistlethwaite has used DOWKER NOTATION to enumerate the number of PRIME KNOTS of up to 13 crossings, and ALTERNATING KNOTS up to 14 crossings. In this compilation, MIRROR IMAGES are counted as a single knot type. Hoste *et al.* (1998) subsequently tabulated all prime knots up to 16 crossings. Hoste and Weeks are currently begun compiling a list of 17-crossing knots (Hoste *et al.* 1998).

The following table gives the number of distinct PRIME, ALTERNATING, NONALTERNATING, TORUS, and SATELLITE KNOTS, in addition to the number of chiral noninvertible c, + amphichiral noninvertible, − amphichiral noninvertible, chiral invertible i, and fully amphichiral and invertible knots a for $n = 3$ to 16 (Hoste *et al.* 1998).

A pictorial enumeration of PRIME KNOTS of up to 10 crossings appears in Rolfsen (1976, Appendix C). Note, however, that in this table, the PERKO PAIR 10–161 and 10–162 are actually identical, and the uppermost crossing in 10–144 should be changed (Jones 1987). The kth knot having n crossings in this (arbitrary) ordering of knots is given the symbol n_k. Another possible representation for knots uses the BRAID GROUP. A knot with $n+1$ crossings is a member of the BRAID GROUP n.

There is no general ALGORITHM to determine if a tangled curve is a knot or if two given knots are interlocked. Haken (1961) and Hemion (1979) have given ALGORITHMS for rigorously determining if two knots are equivalent, but they are too complex to apply even in simple cases (Hoste *et al.* 1998).

If a knot is AMPHICHIRAL, the "amphichirality" is $A=1$, otherwise $A=0$ (Jones 1987). ARF INVARIANTS are designated a. BRAID WORDS are denoted b (Jones 1987). CONWAY'S KNOT NOTATION C for knots up to 10 crossings is given by Rolfsen (1976). Hyperbolic volumes are given (Adams, Hildebrand, and Weeks 1991; Adams 1994). The BRAID INDEX i is given by Jones (1987). ALEXANDER POLYNOMIALS Δ are given in Rolfsen (1976), but with the POLYNOMIALS for 10–083 and 10–086 reversed (Jones 1987). The ALEXANDER POLYNOMIALS are normalized according to Conway, and given in abbreviated form $[a_1, a_2, \ldots$ for $a_1 + a_2(x^{-1}+x)+\ldots$.

The JONES POLYNOMIALS W for knots of up to 10 crossings are given by Jones (1987), and the JONES POLYNOMIALS V can be either computed from these, or taken from Adams (1994) for knots of up to 9 crossings (although most POLYNOMIALS are associated with the wrong knot in the first printing). The JONES POLYNOMIALS are listed in the abbreviated form $\{n\}a_0a_1\ldots$ for $t^{-n}(a_0+a_1t+\ldots)$, and correspond either to the knot depicted by Rolfsen or its MIRROR IMAGE, whichever has the lower POWER of t^{-1}. The HOMFLY POLYNOMIAL $P(\ell, m)$ and KAUFFMAN POLYNOMIAL $F(a, x)$ are given in Lickorish and Millett (1988) for knots of up to 7 crossings.

M. B. Thistlethwaite has tabulated the HOMFLY POLYNOMIAL and KAUFFMAN POLYNOMIAL F for KNOTS of up to 13 crossings.

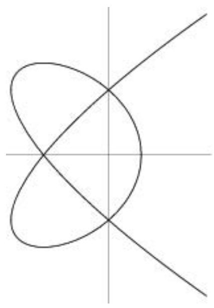
Knot Complement

Let $\mathbb{R}^3$ be the space in which a KNOT K sits. Then the space "around" the knot, i.e., everything but the knot itself, is denoted $\mathbb{R}^3 - K$ and is called the knot complement of K (Adams 1994, p. 84).



If a knot complement is hyperbolic (in the sense that it admits a complete Riemannian metric of constant GAUSSIAN CURVATURE -1), then this metric is unique (Prasad 1973, Hoste *et al.* 1998).

Knot Determinant

The determinant of a knot is $|\Delta(-1)|$, where $\Delta(z)$ is the Alexander polynomial.

Knot Diagram

A picture of a projection of a knot onto a plane. Usually, only double points are allowed (no more than two points are allowed to be superposed), and the double or crossing points must be "genuine crossings" which transverse in the plane. This means that double points must look like the above left diagram, and not the above right one. Also, it is usually demanded that a knot diagram contain the information if the crossings are overcrossings or undercrossings so that the original knot can be reconstructed. The knot diagram of the trefoil knot is illustrated below.

Knot polynomials can be computed from knot diagrams. Such polynomials often (but not always) allow the knots corresponding to given diagrams to be uniquely identified.

Knot Exterior

The exterior of a knot K is the complement of an open solid torus knotted like K. The removed open solid torus is called a tubular neighborhood (Adams 1994, p. 258).

Knot Invariant

A knot invariant is a function from the set of all knots to any other set such that the function does not change as the knot is changed (up to isotopy). In other words, a knot invariant always assigns the same value to equivalent knots (although different knots may have the same knot invariant). Standard knot invariants include the fundamental group of the knot complement, numerical knot invariants (such as Vassiliev invariants), polynomial invariants (knot polynomials such as the Alexander polynomial, Jones polynomial, Kauffman polynomial F, and Kauffman polynomial X), and torsion invariants (such as the torsion number).

Knot Linking

In general, it is possible to link two n-D hyperspheres in $(n+2)$-D space in an infinite number of inequivalent ways. In dimensions greater than $n+2$ in the piecewise linear category, it is true that these spheres are themselves unknotted. However, they may still form nontrivial links. In this way, they are something like higher dimensional analogs of two 1-spheres in 3-D. The following table gives the number of nontrivial ways that two n-D hyperspheres can be linked in k-D.

D of spheres	D of space	Distinct Linkings
23	40	239
31	48	959
102	181	3

102	182	10438319
102	183	3

Two 10-D HYPERSPHERES link up in 12, 13, 14, 15, and 16-D, then unlink in 17-D, link up again in 18, 19, 20, and 21-D. The proof of these results consists of an "easy part" (Zeeman 1962) and a "hard part" (Ravenel 1986). The hard part is related to the calculation of the (stable and unstable) HOMOTOPY GROUPS of SPHERES.

Knot Move

An operation on a knot or link diagram which preserves its crossing number. Thistlethwaite used 13 different moves in generating a list of 16-crossing alternating knots (Hoste *et al.* 1998). While these moves eliminate all duplicate knots up to 13 crossings with only a single exception, there are 9,868 duplicates in his list of 1,018,774 16-crossing knots (Hoste *et al.* 1998).

Knot Problem

The problem of deciding if two KNOTS in 3-space are equivalent such that one can be continuously deformed into another.

Knot Shadow

A KNOT DIAGRAM which does not specify whether crossings are under- or overcrossings.

Knot Sum

Two oriented knots (or links) can be summed by placing them side by side and joining them by straight bars so that orientation is preserved in the sum. This operation is denoted #, so the knot sum of knots K_1 and K_2 is written

$$K_1 \# K_2 = K_2 \# K_1.$$

The KNOT SUM of any number of knots cannot be the UNKNOT unless each knot in the sum is the UNKNOT (Schubert 1949; Steinhaus 1983, p. 265).

See also CONNECTED SUM

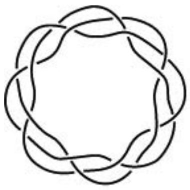
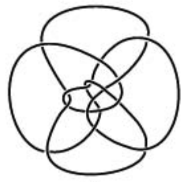
Knot Symmetry

A symmetry of a knot K is a homeomorphism of $\mathbb{R}^3$ which maps K onto itself. More succinctly, a knot symmetry is a homeomorphism of the pair of spaces $(\mathbb{R}^3, K)$. Hoste *et al.* (1998) consider four types of symmetry based on whether the symmetry preserves or reverses orienting of $\mathbb{R}^3$ and K,



1. preserves $\mathbb{R}^3$, preserves K (identity operation),
2. preserves $\mathbb{R}^3$, reverses K,
3. reverses $\mathbb{R}^3$, preserves K,
4. reverses $\mathbb{R}^3$, reverses K.



This then gives the five possible classes of symmetry summarized in the table below.

class	symmetries	knot symmetries
c	1	chiral, noninvertible
$+$	1, 3	$+$ amphichiral, noninvertible
$-$	1, 4	$-$ amphichiral, noninvertible
i	1, 2	chiral, invertible
a	1, 2, 3, 4	$+$ and $-$ amphichiral, invertible

In the case of HYPERBOLIC KNOTS, the symmetry group must be finite and either CYCLIC or DIHEDRAL (Riley 1979, Kodama and Sakuma 1992, Hoste *et al.* 1998). The classification is slightly more complicated for nonhyperbolic knots. Furthermore, all knots with ≤ 8 crossings are either amphichiral or invertible

(Hoste *et al.* 1998). Any symmetry of a prime alternating link must be visible up to flypes in any alternating diagram of the link (Bonahon and Siebermann, Menasco and Thistlethwaite 1993, Hoste *et al.* 1998).

D_{16}

D_9

The following tables (Hoste *et al.* 1998) give the numbers of n-crossing knots belonging to cyclic symmetry groups $\mathbb{Z}_k$ (Sloane's A052411 for $\mathbb{Z}_1$ and A052412 for $\mathbb{Z}_2$) and dihedral symmetry groups D_k (Sloane's A052415 through A052422). Of knots with 16 or fewer crossings, there are only one each having symmetry groups $\mathbb{Z}_3$, D_{14}, and D_{16} (above left). There are only two knots with symmetry group D_9, one hyperbolic (above right), and one a satellite knot. In addition, there are 2, 4, and 10 satellite knots having 14-, 15-, and 16-crossings, respectively, which belong to the dihedral group D_∞.

Knot Theory

The mathematical study of KNOTS. Knot theory considers questions such as the following:

1. Given a tangled loop of string, is it really knotted or can it, with enough ingenuity and/or luck, be untangled without having to cut it?
2. More generally, given two tangled loops of string, when are they deformable into each other?
3. Is there an effective algorithm (or any algorithm to speak of) to make these determinations?

Although there has been almost explosive growth in the number of important results proved since the

discovery of the JONES POLYNOMIAL, there are still many "knotty" problems and conjectures whose answers remain unknown.

Köbe Function

The function

$$f_\theta(z) \equiv \frac{z}{(1 + e^{i\theta} z)^2} \tag{1}$$

defined on the UNIT DISK $|z| < 1$. For $\theta \in [0, 2\pi)$, the Köbe function is a SCHLICHT FUNCTION

$$f(z) = z + \sum_{j=2}^{\infty} a_j z^j \tag{2}$$

with $|a_j| = j$ for all j (Krantz 1999, p. 149). For $\theta = 0$,

$$f_0(z) = \frac{z}{(z-1)^2}, \tag{3}$$

illustrated above.

Koch Antisnowflake

A FRACTAL derived from the KOCH SNOWFLAKE. The base curve and motif for the fractal are illustrated below.

The AREA after the nth iteration is

$$A_n = A_{n-1} - \frac{1}{3} \frac{\ell_{n-1}}{a} \frac{\Delta}{3^n},$$

where Δ is the area of the original EQUILATERAL

TRIANGLE, so from the derivation for the KOCH SNOWFLAKE,

$$A \equiv \lim_{n\to\infty} A_n = (1-\tfrac{3}{5})\Delta = \tfrac{2}{5}\Delta.$$

Koch Island

KOCH SNOWFLAKE

Koch Snowflake

A FRACTAL, also known as the KOCH ISLAND, which was first described by Helge von Koch in 1904. It is built by starting with an EQUILATERAL TRIANGLE, removing the inner third of each side, building another EQUILATERAL TRIANGLE at the location where the side was removed, and then repeating the process indefinitely. The Koch snowflake can be simply encoded as a LINDENMAYER SYSTEM with initial string "F-F-F", STRING REWRITING rule "F" -> "F+F-F+F", and angle 60°. The zeroth through third iterations of the construction are shown above. The fractal can also be constructed using a base curve and motif, illustrated below.

Let N_n be the number of sides, L_n be the length of a single side, ℓ_n be the length of the PERIMETER, and A_n the snowflake's AREA after the nth iteration. Further, denote the AREA of the initial $n=0$ TRIANGLE Δ, and the length of an initial $n=0$ side 1. Then

$$N_n = 3 \cdot 4^n \tag{1}$$

$$L_n = \left(\tfrac{1}{3}\right)^n = 3^{-n} \tag{2}$$

$$\ell_n \equiv N_n L_n = 3\left(\tfrac{4}{3}\right)^n \tag{3}$$

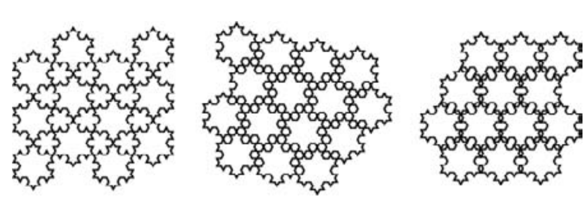
$$\begin{aligned} A_n &= A_{n-1} + \tfrac{1}{4} N_n L_n^2 \Delta = A_{n-1} + \frac{3\cdot 4^n}{4}\left(\frac{1}{3}\right)^{2n}\Delta \\ &= A_{n-1} + \frac{3\cdot 4^{n-1}}{9^n}\Delta = A_{n-1} + \frac{3\cdot 4^{4-1}}{9\cdot 9^{n-1}}\Delta \\ &= A_{n-1} + \tfrac{1}{3}\left(\tfrac{4}{9}\right)^{n-1}\Delta. \end{aligned} \tag{4}$$

The CAPACITY DIMENSION is then

$$\begin{aligned} d_{\text{cap}} &= -\lim_{n\to\infty} \frac{\ln N_n}{\ln L_n} = -\lim_{n\to\infty} \frac{\ln(3\cdot 4)^n}{\ln(3^{-n})} \\ &= \lim_{n\to\infty} \frac{\ln 3 + n\ln 4}{n \ln 3} = \frac{\ln 4}{\ln 3} = \frac{2\ln 2}{\ln 3} \\ &= 1.261859507\ldots. \end{aligned} \tag{5}$$

Now compute the AREA explicitly,

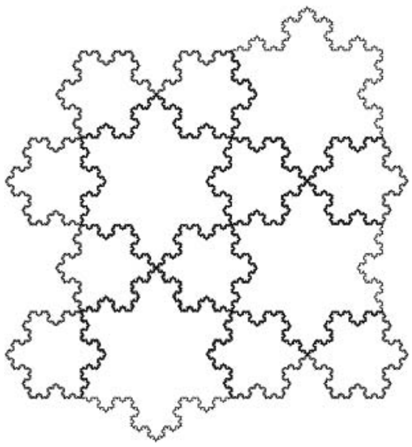
$$A_0 = \Delta \tag{6}$$



$$A_1 = A_0 + \frac{1}{3}\left(\frac{4}{9}\right)^0 \Delta = \Delta\left\{1 + \frac{1}{3}\left(\frac{4}{9}\right)^0\right\} \tag{7}$$

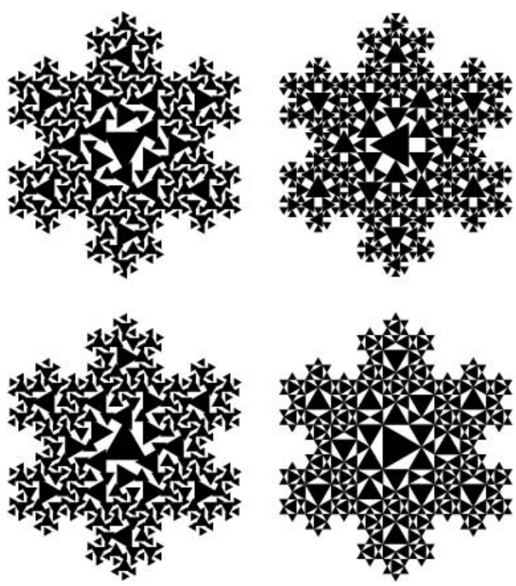
$$A_2 = A_1 + \frac{1}{3}\left(\frac{4}{9}\right)^1 \Delta = \Delta\left\{1 + \frac{1}{3}\left[\left(\frac{4}{9}\right)^0 + \left(\frac{4}{9}\right)^1\right]\right\} \tag{8}$$

$$A_n = \left[1 + \frac{1}{3}\sum_{k=0}^{n}\left(\frac{4}{9}\right)^k\right]\Delta, \tag{9}$$



so as $n \to \infty$,

$$\begin{aligned} A \equiv A_\infty &= \left[1 + \frac{1}{3}\sum_{k=1}^{\infty}\left(\frac{4}{9}\right)^k\right] = \left(1 + \tfrac{1}{3}\,\frac{1}{1-\frac{4}{9}}\right)\Delta \\ &= \tfrac{8}{5}\,\Delta. \end{aligned} \tag{10}$$



Some beautiful TILINGS, a few examples of which are illustrated above, can be made with iterations toward

Koch snowflakes.

In addition, two sizes of Koch snowflakes in AREA ratio 1:3 TILE the PLANE, as shown above (Mandelbrot).

Another beautiful modification of the Koch snowflake involves inscribing the constituent triangles with filled-in triangles, possibly rotated at some angle. Some sample results are illustrated above for 3 and 4 iterations.

Kochansky's Approximation

The approximation for PI given by

$$\pi \approx \sqrt{\frac{40}{3} - 2\sqrt{3}} = \tfrac{1}{3}\sqrt{120 - 18\sqrt{3}} = 3.141533\ldots.$$

In the above figure, let $OA = AF = 1$, and construct the circle centered at $A = (0, 0)$ of radius 1. This intersects O at point $B = (-\sqrt{3}/2,\ 1/2)$. Now construct the circle about B with radius 1. The circles A and B intersect in $C = (-\sqrt{3}/2,\ -1/2)$, and the line

CO intersects the perpendicular to OA through A in the point $D=(-\sqrt{3}/3,\ 0)$. Now construct the point $E=(3-\sqrt{3}/3,\ 0)$ to be a distance 3 along DA. The line segment EF is then of length

$$\sqrt{2^2+\left(3-\tfrac{1}{2}\sqrt{3}\right)^2}=\sqrt{\frac{40}{3}-2\sqrt{3}}.$$

This construction was given by the Polish Jesuit priest Kochansky (Steinhaus 1983).

Kolakoski Sequence

The self-describing sequence consisting of "blocks" of single and double 1s and 2s, where a "block" is a single or double digit that is different from the digit in the preceding block. To construct the sequence, start with the single digit 1 (the first "block"). Here, the single 1 means that block of length one follows the first block. Therefore, require that the next block is 2, giving the sequence 12.

Now, the 2 means that the next (third) block will have length two, so append 11 and obtain the sequence 1211. We have added two 1s, so the fourth and fifth blocks have length one each, giving 12112 and then 121121. As a result of adding 21, we obtain 121121221. As a result of adding 221, we obtain 12112122122112, and so on, giving the sequence 1, 2, 1, 1, 2, 1, 2, 2, 1, 2, 2, 1, 1, 2, ... (Sloane's A006928). The sequence after successive iterations is given by 1, 12, 1211, 121121, 121121221, ..., and the lengths of this sequence after steps $n=1$, 2, ... are given by 1, 2, 4, 6, 9, 14, 22, ... (Sloane's A042942).

If the sequence is started with 1, 2, 2 and the above procedure is undertaken beginning with the last 2, then the virtually identical sequence 1, 2, 2, 1, 1, 2, 1, 2, 2, 1, 2, 2, 1, 1, 2, ... (Sloane's A000002) is obtained. (It is the same as Sloane's A006928, except that the second 2 is doubled.) When presented in this form, the term $a(n)$ gives the length of the nth RUN in the sequence. The lengths after steps $n=1$, 2, ... are then 1, 2, 3, 5, 7, 10, 15, ... (Sloane's A001083), essentially one less than Sloane's A042942.

The question of whether the number of 1s is "asymptotically" equal to the number of 2s is unsettled, although the above plot (which shows the fraction of 1s as a function of number of digits) is certainly consistent with 1 and 2 being equidistributed.

Kolmogorov Criterion

STRONG LAW OF LARGE NUMBERS

Kolmogorov Entropy

Also known as METRIC ENTROPY. Divide PHASE SPACE into D-dimensional HYPERCUBES of CONTENT ϵ^D. Let $P_{i_0,\ldots,i_n}$ be the probability that a trajectory is in HYPERCUBE i_0 at $t=0$, i_1 at $t=T$, i_2 at $t=2T$, etc. Then define

$$K_n = h_K = -\sum_{i_0,\ldots,i_n} P_{i_0,\ldots,i_n} \ln P_{i_0,\ldots,i_n}, \tag{1}$$

where $K_{N+1}-K_N$ is the information needed to predict which HYPERCUBE the trajectory will be in at $(n+1)T$ given trajectories up to nT. The Kolmogorov entropy is then defined by

$$K \equiv \lim_{T\to 0} \lim_{\epsilon\to 0^+} \lim_{N\to\infty} \frac{1}{NT} \sum_{n=0}^{N-1} (K_{n+1}-K_n). \tag{2}$$

The Kolmogorov entropy is related to LYAPUNOV CHARACTERISTIC EXPONENTS by

$$h_K = \int_P \sum_{\sigma_i>0} \sigma_i \, d\mu. \tag{3}$$

Kolmogorov-Arnold-Moser Theorem

A theorem outlined in 1954 by Kolmogorov which was subsequently proved in the 1960s by Arnold and Moser (Tabor 1989, p. 105). It gives conditions under which CHAOS is restricted in extent. Moser's 1962 proof was valid for TWIST MAPS

$$\theta' = \theta + 2\pi f(I) + g(\theta, I) \tag{1}$$

$$I' = I + f(\theta, I). \tag{2}$$

In 1963, Arnold produced a proof for Hamiltonian systems

$$H = H_0(\mathbf{I}) + \epsilon H_1(\mathbf{I}). \tag{3}$$

The original theorem required perturbations $\epsilon \sim 10^{-48}$, although this has since been significantly increased. Arnold's proof required C^∞, and Moser's original proof required C^{333}. Subsequently, Moser's version has been reduced to C^6, then $C^{2+\epsilon}$, although counterexamples are known for C^2. Conditions for applicability of the KAM theorem are:

1. small perturbations,
2. smooth perturbations, and
3. sufficiently irrational WINDING NUMBER.

Moser considered an integrable Hamiltonian function H_0 with a TORUS T_0 and set of frequencies ω having an incommensurate frequency vector $\boldsymbol{\omega}^*$ (i.e., $\boldsymbol{\omega} \cdot \mathbf{k} \neq 0$ for all INTEGERS k_i). Let H_0 be perturbed by some periodic function H_1. The KAM theorem states that, if H_1 is small enough, then for almost every ω^* there exists an invariant TORUS $T(\omega^*)$ of the perturbed system such that $T(\omega^*)$ is "close to" $T_0(\omega^*)$. Moreover, the TORI $T(\omega^*)$ form a set of POSITIVE measures whose complement has a measure which tends to zero as $|H_1| \to 0$. A useful paraphrase of the KAM theorem is, "For sufficiently small perturbation, almost all TORI (excluding those with rational frequency vectors) are preserved." The theorem thus explicitly excludes TORI with rationally related frequencies, that is, $n-1$ conditions of the form

$$\boldsymbol{\omega} \cdot \mathbf{k} = 0. \tag{4}$$

These TORI are destroyed by the perturbation. For a system with two DEGREES OF FREEDOM, the condition of closed orbits is

$$\sigma = \frac{\omega_1}{\omega_2} = \frac{r}{s}. \tag{5}$$

For a QUASIPERIODIC ORBIT, σ is IRRATIONAL. KAM shows that the preserved TORI satisfy the irration-

ality condition

$$\left|\frac{\omega_1}{\omega_2} - \frac{r}{s}\right| > \frac{K(\epsilon)}{s^{2.5}} \tag{6}$$

for all r and s, although not much is known about $K(\epsilon)$.

The KAM theorem broke the deadlock of the small divisor problem in classical perturbation theory, and provides the starting point for an understanding of the appearance of CHAOS. For a HAMILTONIAN SYSTEM, the ISOENERGETIC NONDEGENERACY condition

$$\left|\frac{\partial^2 H_0}{\partial I_j\, \partial I_j}\right| \neq 0 \tag{7}$$

guarantees preservation of most invariant TORI under small perturbations $\epsilon \ll 1$. The Arnold version states that

$$\left|\sum_{k=1}^{n} m_k \omega_k\right| > K(\epsilon)\left(\sum_{k=1}^{n} |m_k|\right)^{-n-1} \tag{8}$$

for all $m_k \in \mathbb{Z}$. This condition is less restrictive than Moser's, so fewer points are excluded.

Kolmogorov-Sinai Entropy

KOLMOGOROV ENTROPY, METRIC ENTROPY

Kolmogorov-Smirnov Test

A goodness-of-fit test for any STATISTICAL DISTRIBUTION. The test relies on the fact that the value of the sample cumulative density function is asymptotically normally distributed.

To apply the Kolmogorov-Smirnov test, calculate the cumulative frequency (normalized by the sample size) of the observations as a function of class. Then calculate the cumulative frequency for a true distribution (most commonly, the NORMAL DISTRIBUTION). Find the greatest discrepancy between the observed and expected cumulative frequencies, which is called the "D-STATISTIC." Compare this against the critical D-STATISTIC for that sample size. If the calculated D-STATISTIC is greater than the critical one, then reject the NULL HYPOTHESIS that the distribution is of the expected form. The test is an R-ESTIMATE.

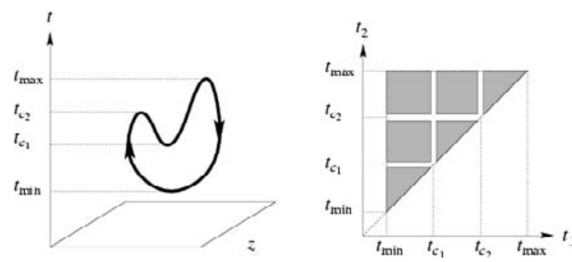
Kontsevich Integral

This entry contributed by SERGEI DUZHIN AND S. CHMUTOV

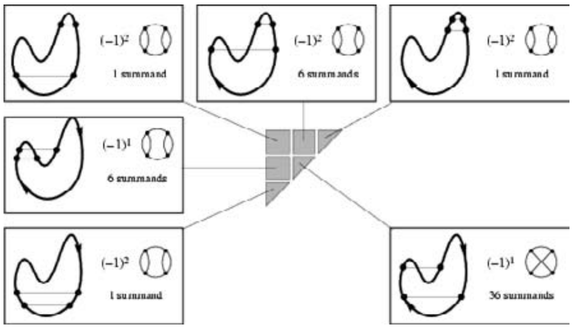


Kontsevich's integral is a far-reaching generalization of the GAUSS INTEGRAL for the LINKING NUMBER, and provides a tool to construct the UNIVERSAL VASSILIEV INVARIANT of a KNOT. In fact, any VASSILIEV KNOT INVARIANT can be derived from it.

To construct the Kontsevich integral, represent the three-dimensional space $\mathbb{R}^3$ as a DIRECT PRODUCT of a complex line $\mathbb{C}$ with coordinate z and a real line $\mathbb{R}$ with coordinate t. The integral is defined for MORSE KNOTS, i.e., knots K embedded in $\mathbb{R}^3 = \mathbb{C}_z \times \mathbb{R}_t$ in such a way that the coordinate t is a MORSE FUNCTION on K, and its values belong to the GRADED COMPLETION $\bar{\mathscr{A}}$ of the ALGEBRA OF CHORD DIAGRAMS $\mathscr{A}$.

The Kontsevich integral $Z(K)$ of the knot K is defined as

$$Z(K) = \sum_{m=0}^{\infty} \frac{1}{(2\pi i)^m} \int_{\substack{t_{\min} < t_1 < \ldots < t_m < t_{\max} \\ t_j \text{ are noncritical}}} \sum_{P = \{(z_j, z_j')\}} (-1)^{\downarrow} D_P \times \bigwedge_{j=1}^{m} \frac{dz_j - dz_j'}{z_j - z_j'}, \quad (1)$$



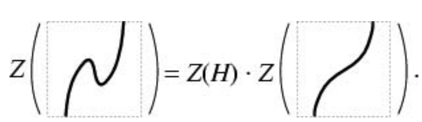
where the ingredients of this formula have the following meanings. The real numbers $t_{\min}$ and $t_{\max}$ are the minimum and the maximum of the function t on K.

The integration domain is the m-dimensional simplex $t_{\min} < t_1 < \ldots < t_m < t_{\max}$ divided by the critical values into a certain number of connected components. For example, for the embedding of the unknot and $m = 2$ (left figure), the corresponding integration domain has six connected components, illustrated in the right figure above.

The number of summands in the integrand is constant in each connected component of the integration domain, but can be different for different components. In each plane $\{t = t_j\} \subset \mathbb{R}^3$, choose an unordered pair of distinct points (z_j, t_j) and (z_j', t_j) on K so that $z_j(t_j)$ and $z_t'(t_j)$ are continuous functions. Denote by $P = \{(z_j, z_j')\}$ the set of such pairs for $j = 1, \ldots, m$, then the integrand is the sum over all choices of P. In the example above, for the component $\{t_{\min} < t_1 < t_{c_1},\ t_{c_2} < t_2 < t_{\max}\}$, we have only one possible pair of points on the levels $\{t = t_1\}$ and $\{t = t_2\}$. Therefore, the sum over P for this component consists of only one summand. In contrast, in the component $\{t_{\min} < t_1 < t_{c_1}, t_{c_1} < t_2 < t_{c_2}\}$, we still have only one possibility for the level $\{t = t_1\}$, but the plane $\{t = t_2\}$ intersects our knot K in four points. So we have $\binom{4}{2} = 6$ possible pairs (z_2, z_2'), and the total number of summands is six (see the picture below).

For a pairing P the symbol "$\downarrow$" denotes the number of points (z_j, t_j) or (z_j', t_j) in P where the coordinate t decreases along the ORIENTATION of K.

Fix a pairing P, consider the knot K as an oriented circle, and connect the points (z_j, t_j) and (z'_j, t_j) by a chord to obtain a chord diagram with m chords. The corresponding element of the algebra $\mathscr{A}$ is denoted D_P. In the picture above, one of the possible pairings, the corresponding CHORD DIAGRAM with the sign $(-1)^{\downarrow}$, and the number of summands of the integrand (some of which are equal to zero in $\mathscr{A}$ due to a ONE-TERM RELATION) are shown for each connected component.



Over each connected component, z_j and z'_j are SMOOTH FUNCTIONS in t_j. By

$$\bigwedge_{j=1}^{m} \frac{dz_j - dz'_j}{z_j - z'_j}$$

we mean the PULLBACK of this form to the integration domain of variables $t_1, ..., t_m$. The integration domain is considered with the ORIENTATION of the space $\mathbb{R}^m$ defined by the natural order of the coordinates $t_1, ..., t_m$.

By convention, the term in the Kontsevich integral corresponding to $m = 0$ is the (only) CHORD DIAGRAM of order 0 with coefficient one. It represents the unit of the algebra $\mathscr{A}$.

The Kontsevich integral is convergent thanks to ONE-TERM RELATIONS. It is invariant under DEFORMATIONS of the knot in the class of MORSE KNOTS. Unfortunately, the Kontsevich integral is not invariant under deformations that change the number of critical points of the function t. However, the formula shows how the integral changes under such deformations:

In the above equation, the graphical arguments of Z represent two embeddings of an arbitrary knot, differing only in the illustrated fragment,

H is the *hump* (i.e, the UNKNOT embedded in $\mathbb{R}^3$ in the specified way; illustrated above), and the product is the product in the completed algebra $\bar{\mathscr{A}}$ of CHORD DIAGRAMS. The last equality allows the definition of the UNIVERSAL VASSILIEV INVARIANT by the formula

$$I(K) = \frac{Z(K)}{Z(H)^{c/2}}, \tag{2}$$

where c denotes the number of critical points of K and quotient means division in the algebra $\bar{\mathscr{A}}$ according to the rule $(1+a)^{-1} = 1 - a + a^2 - a^3 + \ldots$. The UNIVERSAL VASSILIEV INVARIANT $I(K)$ is invariant under an arbitrary DEFORMATION of K.

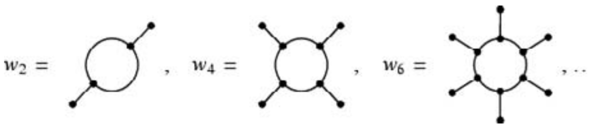
Consider a function w on the set of CHORD DIAGRAMS with m chords satisfying ONE- AND FOUR-TERM RELATIONS (a WEIGHT SYSTEM). Applying this function to the UNIVERSAL VASSILIEV INVARIANT $w(I(K))$, we get a numerical knot invariant. This invariant will be a VASSILIEV INVARIANT of order m, and any VASSILIEV INVARIANT can be obtained in this way.

The Kontsevich integral behaves in a nice way with respect to the natural operations on knots, such as mirror reflection, changing the orientation of the knot, and mutation of knots. In a proper normalization it is multiplicative under the CONNECTED SUM of knots:

$$I'(K_1 \# K_2) = I'(K_1)I'(K_2), \tag{3}$$

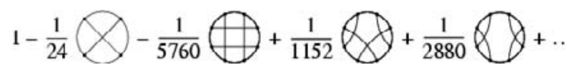
where $I'(K) = Z(H)I(K)$. For any knot K the coefficients in the expansion of $Z(K)$ over an arbitrary basis consisting of CHORD DIAGRAMS are rational (Kontsevich 1993, Le and Murakami 1996).

The task of computing the Kontsevich integral is very difficult. The explicit expression of the universal Vassiliev invariant $I(K)$ is currently known only for the UNKNOT,



$$I(O) = \exp\left(\sum_{n=0}^{\infty} b_{2n} w_{2n}\right) \tag{4}$$

$$= 1 + \left(\sum_{n=0}^{\infty} b_{2n} w_{2n}\right) + \frac{1}{2}\left(\sum_{n=0}^{\infty} b_{2n} w_{2n}\right)^2 + \ldots. \tag{5}$$



(Bar-Natan *et al.* 1997). Here, b_{2n} are MODIFIED BERNOULLI NUMBERS, i.e., the coefficients of the TAYLOR SERIES

$$\sum_{n=0}^{\infty} b_{2n} x^{2n} = \frac{1}{2} \ln\left(\frac{e^{x/2} - e^{-x/2}}{\frac{1}{2}x}\right) \tag{6}$$

($b_2 = 1/48$, $b_4 = -1/5760$, ...; Sloane's A057868), and w_{2n} are the *wheels*, i.e., diagrams of the form

The linear combination is understood as an element of the ALGEBRA OF CHINESE CHARACTERS $\mathcal{B}$, which is isomorphic to the ALGEBRA OF CHORD DIAGRAMS $\mathcal{A}$. Expressed through CHORD DIAGRAMS, the beginning of this series looks as follows:

The Kontsevich integral was invented by Kontsevich (1993), and detailed expositions can be found in Arnol'd (1994), Bar-Natan (1995), and Chmutov and Duzhin (2000).

Korteweg-de Vries Equation

The PARTIAL DIFFERENTIAL EQUATION

$$u_t + u_{xxx} - 6uu_x = 0 \tag{1}$$

(Lamb 1980; Zwillinger 1997, p. 131), often abbreviated "KdV."

The so-called generalized KdV equation is given by

$$u_t + uu_x - u_{xxxxx} = 0 \tag{2}$$

(Boyd 1986; Zwillinger 1997, p. 131). The so-called deformed KdV equation is given by

$$u_t + \frac{\partial}{\partial x}\left(u_{xx} - 2\eta u^3 - \frac{3}{2}\,\frac{uu_x^2}{\eta + u^2}\right) = 0 \tag{3}$$

(Dodd and Fordy 1983; Zwillinger 1997, p. 133), and the modified KdV equation is given by

$$u_t + u_{xxx} \pm 6u^2 u_x = 0 \tag{4}$$

(Calogero and Degasperis 1982, p. 51; Tabor 1990, p. 304; Zwillinger 1997, p. 133), or

$$u_t + u_{xxx} - \tfrac{1}{8}\,u_x^3 + u_x(Ae^u + B + Ce^{-u}) = 0 \tag{5}$$

(Dodd and Fordy 1983; Zwillinger 1997, p. 133).

The cylindrical KdV equation is given by

$$u_t + u_{xxx} - 6uu_x + \frac{u}{2t} = 0 \tag{6}$$

(Calogero and Degasperis 1982, p. 50; Zwillinger 1997, p. 131), and the spherical KdV by

$$u_t + u_{xxx} - 6uu_x + \frac{u}{t} = 0 \tag{7}$$

(Calogero and Degasperis 1982, p. 51; Zwillinger 1997, p. 132).

Kramp's Symbol

The symbol defined by

$$c^{a/b} \equiv c(c+b)(c+2b)\cdots[c+(a-1)b] \quad (1)$$

$$= b^a \left(\frac{c}{b}\right)_a \quad (2)$$

$$= \frac{b^a \Gamma\left(a + \frac{c}{b}\right)}{\Gamma\left(\frac{c}{b}\right)}, \quad (3)$$

where $(a)_n$ is the POCHHAMMER SYMBOL and $\Gamma(z)$ is the GAMMA FUNCTION. Note that the definition by Erdélyi *et al.* (1981, p. 52) incorrectly gives the PREFACTOR of (3) as b^{a-1}.

Krattenthaler Matrix Inversion Formula

Let (a_i) and (b_i) be sequences of complex numbers such that $b_j \neq b_k$ for $j \neq k$, and let the LOWER TRIANGULAR MATRICES $F = (F(n, k))$ and $G = (G(n, k))$ be defined as

$$F(n, k) = \frac{\prod_{j=k}^{n-1}(a_j + k)}{\prod_{j=k+1}^{n}(b_j - b_k)}$$

and

$$G(n, k) = \frac{a_k + b_k}{a_n + b_n} \frac{\prod_{j=k+1}^{n}(a_j + b_n)}{\prod_{j=k}^{n-1}(b_j - b_n)},$$

where the product over an EMPTY SET is 1. Then F and G are MATRIX INVERSES (Bhatnagar 1995, pp. 16–17). This result simplifies to the GOULD AND HSU MATRIX INVERSION FORMULA when $b_k = k$, to Carlitz's q-analog for $b_k = q^k$ (Carlitz 1972), and to Bressoud's matrix theorem for $b_k = q^{-k} + aq^k$ and $a_k = -(aq^{-j}/b) - bq^j$ (Bressoud 1983).

The formula can be extended to a summation theorem which generalizes Gosper's bibasic sum (Gasper and Rahman 1990, p. 240; Bhatnagar 1995, p. 19).

Krawtchouk Polynomial

Let $\alpha(x)$ be a STEP FUNCTION with the JUMP

$$j(x) = \binom{N}{x} p^x q^{N-x} \quad (1)$$

at $x = 0, 1, ..., N$, where $p > 0$, $q > 0$, and $p + q = 1$. Then the Krawtchouk polynomial is defined by

$$k_n^{(p)}(x, N) = \sum_{\nu=0}^{n} (-1)^{n-\nu} \binom{N-x}{n-\nu} \binom{x}{\nu} p^{n-\nu} q^{\nu}, \quad (2)$$

$$= (-1)^n \binom{N}{n} p^n {}_2F_1(-n, -x; -N; 1/p) \quad (3)$$

$$= \frac{(-1)^n p^n}{n!} \frac{\Gamma(N-x+1)}{\Gamma(N-x-n+1)}$$

$$\times {}_2F_1(-n, -x; N-x-n+1; (p-1)/p). \quad (4)$$

for $n = 0, 1, ..., N$. The first few Krawtchouk polynomials are

$$k_0^{(p)}(x, N) = 1$$

$$k_1^{(p)}(x, N) = -Np + x$$

$$k_2^{(p)}(x, N) = \tfrac{1}{2}[N^2p^2 + x(2p + x - 1) - Np(p + 2x)].$$

Koekoek and Swarttouw (1998) define the Krawtchouk polynomial without the leading coefficient as

$$K_n(x; p, N) = {}_2F_1(-n, -x; -N; 1/p). \quad (5)$$

The Krawtchouk polynomials have WEIGHT FUNCTION

$$w = \frac{N! p^x q^{N-x}}{\Gamma(1+x)\Gamma(N+1-x)}, \quad (6)$$

where $\Gamma(x)$ is the GAMMA FUNCTION, RECURRENCE RELATION

$$(n+1)k_{n+1}^{(p)}(x, N) + pq(N-n+1)k_{n-1}^{(p)}(x, N)$$

$$= [x - n - (N-2)]k_n^{(p)}(x, N), \quad (7)$$

and squared norm

$$\frac{N!}{n!(N-n)!}(pq)^n. \quad (8)$$

It has the limit

$$\lim_{n\to\infty}\left(\frac{2}{Npq}\right)^{n/2} n!k_n^{(p)}(Np+\sqrt{2Npq}\,s,\ N)=H_n(s), \quad (9)$$

where $H_n(x)$ is a HERMITE POLYNOMIAL.

The Krawtchouk polynomials are a special case of the MEIXNER POLYNOMIALS OF THE FIRST KIND.

Kronecker Decomposition Theorem

Every FINITE ABELIAN GROUP can be written as a GROUP DIRECT PRODUCT of CYCLIC GROUPS of PRIME POWER ORDERS. In fact, the number of nonisomorphic ABELIAN FINITE GROUPS $a(n)$ of any given ORDER n is given by writing n as

$$n=\prod_i p_i^{\alpha_i},$$

where the p_i are distinct PRIME FACTORS, then

$$a(n)=\prod_i P(\alpha_i),$$

where $P(n)$ is the PARTITION FUNCTION. This gives 1, 1, 1, 2, 1, 1, 1, 3, 2, ... (Sloane's A000688).

See also ABELIAN GROUP, FINITE GROUP, ORDER (GROUP), PARTITION FUNCTION P

Kronecker Delta

The simplest interpretation of the Kronecker delta is as the discrete version of the DELTA FUNCTION defined by

$$\delta_{ij}\equiv\begin{cases}0 & \text{for } i\neq j\\ 1 & \text{for } i=j.\end{cases} \quad (1)$$

It has the COMPLEX GENERATING FUNCTION

$$\delta_{mn} = \frac{1}{2\pi i} \int z^{m-n-1}\, dz, \qquad (2)$$

where m and n are INTEGERS. In 3-space, the Kronecker delta satisfies the identities

$$\delta_{ii} = 3 \qquad (3)$$

$$\delta_{ij}\epsilon_{ijk} = 0 \qquad (4)$$

$$\epsilon_{ipq}\epsilon_{jpg} = 2\delta_{ij} \qquad (5)$$

$$\epsilon_{ijk}\epsilon_{pqk} = \delta_{ip}\delta_{jq} - \delta_{iq}\delta_{jp}, \qquad (6)$$

where EINSTEIN SUMMATION is implicitly assumed, $i, j = 1, 2, 3$, and ϵ_{ijk} is the PERMUTATION SYMBOL.

Technically, the Kronecker delta is a TENSOR defined by the relationship

$$\delta_l^k \frac{\partial x_i'}{\partial x_k} \frac{\partial x_l}{\partial x_j'} = \frac{\partial x_i'}{\partial x_k} \frac{\partial x_k}{\partial x_j'} = \frac{\partial x_j'}{\partial x_j'}. \qquad (7)$$

Since, by definition, the coordinates x_i and x_j are independent for $i \neq j$,

$$\frac{\partial x_i'}{\partial x_j'} = \delta_j'^i, \qquad (8)$$

so

$$\delta_j'^i = \frac{\partial x_i'}{\partial x_k} \frac{\partial x_l}{\partial x_j'} \delta_l^k, \qquad (9)$$

and δ_j^i is really a mixed second-RANK TENSOR. It satisfies

$$\delta_{ab}^{jk} = \epsilon_{abi}\epsilon^{jki} = \delta_a^j\delta_b^k - \delta_a^k\delta_b^j \qquad (10)$$

$$\delta_{abjk} = g_{aj}g_{bk} - g_{ak}g_{bj} \qquad (11)$$

$$\epsilon_{aij}\epsilon^{bij} = \delta_{ai}^{bi} = 2\delta_a^b. \qquad (12)$$

The generalization of the Kronecker delta viewed as a tensor is called the PERMUTATION TENSOR.

See also DELTA FUNCTION, PERMUTATION SYMBOL, PERMUTATION TENSOR

Kronecker Product

MATRIX DIRECT PRODUCT

Kronecker Symbol

An extension of the JACOBI SYMBOL (n/m) to all INTEGERS. It is variously written as (n/m) or $\left(\frac{n}{m}\right)$ (Cohn 1980) or $(n|m)$ (Dickson 1957). The Kronecker symbol can be computed using the normal rules for the JACOBI SYMBOL

$$\left(\frac{ab}{cd}\right) = \left(\frac{a}{cd}\right)\left(\frac{b}{cd}\right) = \left(\frac{ab}{c}\right)\left(\frac{ab}{d}\right)$$
$$= \left(\frac{a}{c}\right)\left(\frac{b}{c}\right)\left(\frac{a}{d}\right)\left(\frac{b}{d}\right) \qquad (1)$$

plus additional rules for $m = -1$,

$$(n/-1) = \begin{cases} -1 & \text{for } n < 0 \\ 1 & \text{for } n > 0, \end{cases} \qquad (2)$$

and $m = 2$. The definition for $(n/2)$ is variously written as

$$(n/2) = \begin{cases} 0 & \text{for } n \text{ even} \\ 1 & \text{for } n \text{ odd, } n \equiv \pm 1 \pmod 8 \\ -1 & \text{for } n \text{ odd, } n \equiv \pm 3 \pmod 8 \end{cases} \qquad (3)$$

or

$$(n/2) \equiv \begin{cases} 0 & \text{for } 4|n \\ 1 & \text{for } n \equiv 1 \pmod 8 \\ -1 & \text{for } n \equiv 5 \pmod 8 \\ \text{undefined} & \text{otherwise} \end{cases} \qquad (4)$$

(Cohn 1980). Cohn's form "undefines" $(n/2)$ for SINGLY EVEN NUMBERS $n \equiv 2 \pmod 4$ and $n \equiv -1, 3 \pmod 8$, probably because no other values are needed in applications of the symbol involving the DISCRIMINANTS d of QUADRATIC FIELDS, where $m > 0$ and d always satisfies $d \equiv 0, 1 \pmod 4$.

The KRONECKER SYMBOL is a REAL CHARACTER modulo n, and is, in fact, essentially the only type of REAL PRIMITIVE CHARACTER (Ayoub 1963).

Kronecker's Algorithm

A POLYNOMIAL FACTORIZATION algorithm that proceeds by considering the vector of coefficients of a polynomial P, calculating $b_i = P(i)/a_i$, constructing the LAGRANGE INTERPOLATING POLYNOMIALS from the conditions $A(i) = a_i$ and $B(i) = b_i$, and checking to see which are factorizations.

See also POLYNOMIAL FACTORIZATION

Kronecker's Approximation Theorem

If θ is a given IRRATIONAL NUMBER, then the sequence of numbers $\{n\theta\}$, where $\{x\} \equiv x - \lfloor x \rfloor$, is DENSE in the unit interval. Explicitly, given any α, $0 \leq \alpha \leq 1$, and given any $\epsilon > 0$, there exists a POSITIVE INTEGER k such that

$$|\{k\theta\} - \alpha| < \epsilon.$$

Therefore, if $h = \lfloor k\theta \rfloor$, it follows that $|k\theta - h - \alpha| < \epsilon$. The restriction on α can be removed as follows. Given *any* real α, any irrational θ, and any $\epsilon > 0$, there exist integers h and k with $k > 0$ such that

$$|k\theta - h - \alpha| < \epsilon.$$

Krull Dimension

If R is a RING (commutative with 1), the height of a PRIME IDEAL p is defined as the SUPREMUM of all n so that there is a chain $p_0 \subset \cdots p_{n-1} \subset p_n = p$ where all p_i are distinct PRIME IDEALS. Then, the Krull dimension of R is defined as the SUPREMUM of all the heights of all its PRIME IDEALS.

KS Entropy

METRIC ENTROPY

k-Statistic

The ith k-statistic k_i is an UNBIASED ESTIMATOR of the CUMULANT κ_i of a given DISTRIBUTION, i.e., k_i is defined so that $\langle k_i \rangle = \kappa_i$, where $\langle x \rangle$ denotes the EXPECTATION VALUE of x (Kenney and Keeping 1951, p. 189). For a SAMPLE SIZE n, the first few k-statistics are given by

$$k_1 = \mu \quad (1)$$

$$k_2 = \frac{n}{n-1} m_2 \quad (2)$$

$$k_3 = \frac{n^2}{(n-1)(n-2)} m_3 \quad (3)$$

$$k_4 = \frac{n^2[(n+1)m_4 - 3(n-1)m_2^2]}{(n-1)(n-2)(n-3)}, \quad (4)$$

where μ is the sample MEAN, m_2 is the SAMPLE VARIANCE, and m_i is the sample ith CENTRAL MOMENT

(Kenney and Keeping 1951, pp. 109–110, 163–165, and 189; Kenney and Keeping 1962).

The k-statistics can be obtained by defining the sums of the rth powers of the data points as

$$s_r \equiv \sum_{i=1}^{n} X_i^r, \tag{5}$$

then the CENTRAL MOMENTS m_i are given in terms of the s_r by

$$m_2 = -\frac{s_1^2}{n^2} + \frac{s_2}{n} \tag{6}$$

$$m_3 = \frac{2s_1^3}{n^3} - \frac{3s_1s_2}{n^2} + \frac{s_3}{n} \tag{7}$$

$$m_4 = -\frac{3s_1^4}{n^4} + \frac{6s_1^2s_2}{n^3} - \frac{4s_1s_3}{n^2} + \frac{s_4}{n}. \tag{8}$$

Taking the raw expectations of these equations and expressing the answers in terms of moments m_i using

$$m_i = \frac{s_i}{n} \tag{9}$$

then gives the expectation values of the *observed* central moments m_i in terms of the population central moments as

$$\langle m_2 \rangle = \frac{n-1}{n}\,\mu^2 \tag{10}$$

$$\langle m_3 \rangle = \frac{(n-1)(n-2)}{n^2}\,\mu_3 \tag{11}$$

$$\langle m_4 \rangle = \frac{(n-1)[(n^2-3n+3)\mu_4 + 3(2n-3)\mu_2^2]}{n^3}, \tag{12}$$

together with

$$\langle m_2^2 \rangle = \frac{(n-1)[(n-1)\mu_4 + (n^2-2n+3)\mu_2^2]}{n^3} \tag{13}$$

(Kenney and Keeping 1951, p. 189). Solving for the population central moments μ_i in terms of the expectation values of the observed central moments then gives the formulas for the k-statistics, e.g., (10) becomes

$$\mu_2 = \frac{n}{n-1}\langle m_2 \rangle, \tag{14}$$

so

$$k_2 = \frac{n}{n-1}\,m_2 \tag{15}$$

is an UNBIASED ESTIMATOR for $\kappa_2 = \mu_2$.

In terms of the power sums, the k-statistics can then be written as

$$k_2 = \frac{ns_2 - s_1^2}{n(n-1)} \tag{16}$$

$$k_3 = \frac{2s_1^3 - 3ns_1s_2 + n^2s_3}{n(n-1)(n-2)} \tag{17}$$

$$k_4 = \frac{-6s_1^4 + 12ns_1^2s_2 - 3n(n-1)s_2^2 - 4n(n+1)s_1s_3 + n^2(n+1)s_4}{n(n-1)(n-2)(n-3)}. \tag{18}$$

The VARIANCE $\mathrm{var}(k_2)$ of k_2 is given by the second central expectation of k_2 which, when expressed in terms of CUMULANTS, becomes

$$\mathrm{var}(k_2) = \frac{\kappa_4}{n} + \frac{2\kappa_2^2}{n-1}. \tag{19}$$

The UNBIASED ESTIMATOR of $\mathrm{var}(k_2)$ is

$$\widehat{\mathrm{var}(k_2)} = \frac{2k_2^2n + (n-1)k_4}{n(n+1)} \tag{20}$$

(Kenney and Keeping 1951, p. 189).

The VARIANCE of k_3 can be expressed in terms of CUMULANTS by

$$\mathrm{var}(k_3) = \frac{\kappa_6}{n} + \frac{9\kappa_2\kappa_4}{n-1} + \frac{9\kappa_3^2}{n-1} + \frac{6n\kappa_2^3}{(n-1)(n-2)}, \tag{21}$$

and the UNBIASED ESTIMATOR for $\mathrm{var}(k_3)$ is

$$\widehat{\mathrm{var}(k_3)} = \frac{6k_2^2n(n-1)}{(n-2)(n+1)(n+3)} \tag{22}$$

(Kenney and Keeping 1951, p. 190).

For a *finite* population, let a SAMPLE SIZE n be taken from a population size N. Then UNBIASED ESTIMATORS M_1 for the population MEAN μ, M_2 for the population VARIANCE μ_2, G_1 for the population SKEWNESS γ_1, and G_2 for the population KURTOSIS γ_2 are

$$M_1 = \mu \tag{23}$$

$$M_2 = \frac{N-n}{n(N-1)}\,\mu_2 \tag{24}$$

$$G_1 = \frac{N-2n}{N-2}\sqrt{\frac{N-1}{n(N-n)}}\,\gamma_1 \tag{25}$$

$$G_2 = \frac{(N-1)(N^2-6Nn+N+6n^2)\gamma_2}{n(N-2)(N-3)(N-n)} - \frac{6N(Nn+N-n^2-1)}{n(N-2)(N-3)(N-n)} \tag{26}$$

(Church 1926, p. 357; Carver 1930; Irwin and Kendall 1944; Kenney and Keeping 1951, p. 143), where γ_1 is the sample SKEWNESS and γ_2 is the sample KURTOSIS.

k-Subset

A k-subset is a SUBSET of a set on n elements containing exactly k elements. The number of k-subsets on n elements is therefore given by the BINOMIAL COEFFICIENT $\binom{n}{k}$. For example, there are $\binom{3}{2}=3$ 2-subsets of $\{1, 2, 3\}$, namely $\{1, 2\}$, $\{1, 3\}$, and $\{2, 3\}$. The k-subsets on a list can be enumerated using `KSubsets[`*list*`, `*k*`]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``).

The total number of distinct k-subsets on a set of n elements (i.e., the number of SUBSETS) is given by

$$\sum_{k=0}^{n}\binom{n}{k}=2^n.$$

K-Theory

A branch of mathematics which brings together ideas from ALGEBRAIC GEOMETRY, LINEAR ALGEBRA, and NUMBER THEORY. In general, there are two main types of K-theory: topological and algebraic.

Topological K-theory is the "true" K-theory in the sense that it came first. Topological K-theory has to do with VECTOR BUNDLES over TOPOLOGICAL SPACES. Elements of a K-theory are STABLE EQUIVALENCE classes of VECTOR BUNDLES over a TOPOLOGICAL SPACE. You can put a RING structure on the collection of STABLY EQUIVALENT bundles by defining ADDITION through the WHITNEY SUM, and MULTIPLICATION through the TENSOR PRODUCT of VECTOR BUNDLES. This defines "the reduced real topological K-theory of a space."

"The reduced K-theory of a space" refers to the same construction, but instead of REAL VECTOR BUNDLES, COMPLEX VECTOR BUNDLES are used. Topological K-theory is significant because it forms a generalized COHOMOLOGY theory, and it leads to a solution to the vector fields on spheres problem, as well as to an understanding of the J-homeomorphism of HOMOTOPY THEORY.

Algebraic K-theory is somewhat more involved. Swan (1962) noticed that there is a correspondence between the CATEGORY of suitably nice TOPOLOGICAL SPACES (something like regular HAUSDORFF SPACES) and C*-ALGEBRAS. The idea is to associate to every SPACE the C*-ALGEBRA of CONTINUOUS MAPS from that SPACE to the REALS.

A VECTOR BUNDLE over a SPACE has sections, and these sections can be multiplied by CONTINUOUS FUNCTIONS to the REALS. Under Swan's correspondence, VECTOR BUNDLES correspond to modules over the C*-ALGEBRA of CONTINUOUS FUNCTIONS, the MODULES being the modules of sections of the VECTOR BUNDLE. This study of MODULES over C*-ALGEBRA is the starting point of algebraic K-theory.

The QUILLEN-LICHTENBAUM CONJECTURE connects algebraic K-theory to Étale cohomology.

k-Tuple Conjecture

The first of the HARDY-LITTLEWOOD CONJECTURES. The k-tuple conjecture states that the asymptotic number of PRIME CONSTELLATIONS can be computed explicitly. In particular, unless there is a trivial divisibility condition that stops p, $p+a_1$, ..., $p+a_k$ from consisting of PRIMES infinitely often, then such PRIME CONSTELLATIONS will occur with an asymptotic density which is computable in terms of a_1, ..., a_k. Let $0<m_1<m_2<\ldots<m_k$, then the k-tuple conjecture predicts that the number of PRIMES $p\le x$ such that

$p+2m_1, p+2m_2, ..., p+2m_k$ are all PRIME is

$$P(x;\ m_1,\ m_2,\ \ldots,\ m_k) \sim C(m_1,\ m_2,\ \ldots,\ m_k)\int_2^x \frac{dt}{\ln^{k+1} t}, \qquad (1)$$

where

$$C(m_1,\ m_2,\ \ldots,\ m_k) = 2k \prod_q \frac{1-\frac{w(q;\ m_1,\ m_2,\ldots,\ m_k)}{q}}{\left(1-\frac{1}{q}\right)^{k+1}}, \qquad (2)$$

the product is over ODD PRIMES q, and

$$w(q;\ m_1,\ m_2,\ \ldots,\ m_k) \qquad (3)$$

denotes the number of distinct residues of 0, m_1, ..., m_k (mod q) (Halberstam and Richert 1974, Odlyzko). If $k=1$, then this becomes

$$C(m) = 2\prod_q \frac{q(q-2)}{(q-1)^2}\prod_{q|m}\frac{q-1}{q-2}. \qquad (4)$$

This conjecture is generally believed to be true, but has not been proven (Odlyzko *et al.*). The following special case of the conjecture is sometimes known as the PRIME PATTERNS CONJECTURE. Let S be a FINITE set of INTEGERS. Then it is conjectured that there exist infinitely many k for which $\{k+s : s\in S\}$ are all PRIME IFF S does not include all the RESIDUES of any PRIME. The TWIN PRIME CONJECTURE is a special case of the prime patterns conjecture with $S=\{0,2\}$. This conjecture also implies that there are arbitrarily long ARITHMETIC PROGRESSIONS of PRIMES.

See also ARITHMETIC PROGRESSION, DIRICHLET'S THEOREM, HARDY-LITTLEWOOD CONJECTURES, K-TUPLE CONJECTURE, PRIME ARITHMETIC PROGRESSION, PRIME CONSTELLATION, PRIME QUADRUPLET, PRIME PATTERNS CONJECTURE, TWIN PRIME CONJECTURE, TWIN PRIMES

Kuen Surface

A special case of ENNEPER'S NEGATIVE CURVATURE SURFACES which can be given parametrically by

$$x = \frac{2(\cos u + u\sin u)\sin v}{1+u^2\sin^2 v} \qquad (1)$$

$$= \frac{2\sqrt{1+u^2}\cos(u-\tan^{-1}u)\sin v}{1+u^2\sin^2 v} \qquad (2)$$

$$y = \frac{2(\sin u + u\cos u)\sin v}{1+u^2\sin^2 v} \qquad (3)$$

$$= \frac{2\sqrt{1+u^2}\sin(u-\tan^{-1}u)\sin v}{1+u^2\sin^2 v} \qquad (4)$$

$$z = \ln\left[\tan\left(\tfrac{1}{2}v\right)\right] + \frac{2\cos v}{1+u^2\sin^2 v} \qquad (5)$$

for $v\in[0,\ \pi)$, $u\in[0,\ 2\pi)$ (Reckziegel *et al.* 1986; Gray 1997, p. 496).

The coefficients of the FIRST FUNDAMENTAL FORM are

$$E = \frac{16u^2\sin^2 v}{[2+u^2-u^2\cos^2(2v)]^2} \qquad (6)$$

$$F = 0 \qquad (7)$$

$$G = \csc^2 v - \frac{16u^2\sin^2 v}{[2+u^2-u^2\cos^2(2v)]^2}, \qquad (8)$$

the SECOND FUNDAMENTAL FORM coefficients are

$$e = \frac{4u[2-u^2+u^2\cos^2(2v)]\sin v}{[2+u^2-u^2\cos^2(2v)]^2}, \qquad (9)$$

$$f = 0 \qquad (10)$$

$$g = \frac{4u[2-u^2+u^2\cos^2(2v)]\csc v}{[2+u^2-u^2\cos^2(2v)]^2}, \qquad (11)$$

and the surface area element is

$$dS = \frac{4u[2-u^2+u^2\cos^2(2v)]}{[2+u^2-u^2\cos^2(2v)]^2}. \qquad (12)$$

The GAUSSIAN and MEAN CURVATURES are

$$K = -1 \quad (13)$$

$$H = -\frac{\csc v}{4u} + \frac{1}{4} u \sin v \left[1 + \frac{8}{2 - u^2 + u^2 \cos(2v)}\right], \quad (14)$$

so the Kuen surface has constant NEGATIVE GAUSSIAN CURVATURE, and the PRINCIPAL CURVATURES are

$$\kappa_1 = \frac{4u \sin v}{2 - u^2 + u^2 \cos(2v)} \quad (15)$$

$$\kappa_2 = -\frac{[2 - u^2 + u^2 \cos(2v)] \csc v}{4u} \quad (16)$$

(Gray 1997, p. 496).

Kuhn-Tucker Theorem

A theorem in nonlinear programming which states that if a regularity condition holds and f and the functions h_j are convex, then a solution x^0 which satisfies the conditions h_j for a VECTOR of multipliers λ is a GLOBAL MINIMUM. The Kuhn-Tucker theorem is a generalization of LAGRANGE MULTIPLIERS. FARKAS'S LEMMA is key in proving this theorem.

See also FARKAS'S LEMMA, LAGRANGE MULTIPLIER

Kuiper Statistic

A statistic defined to improve the KOLMOGOROV-SMIRNOV TEST in the TAILS.

See also ANDERSON-DARLING STATISTIC

Kulikowski's Theorem

For every POSITIVE INTEGER n, there exists a SPHERE which has exactly n LATTICE POINTS on its surface. The SPHERE is given by the equation

$$(x-a)^2 + (y-b)^2 + (z-\sqrt{2})^2 = c^2 + 2,$$

where a and b are the coordinates of the center of the so-called SCHINZEL CIRCLE

$$\begin{cases} \left(x - \frac{1}{2}\right)^2 + y^2 = \frac{1}{4}\, 5^{k-1} & \text{for } n = 2k \text{ even} \\ \left(x - \frac{1}{3}\right)^2 + y^2 = \frac{1}{9}\, 5^{2k} & \text{for } n = 2k+1 \text{ odd} \end{cases}$$

and c is its RADIUS.

Kullback-Leibler Distance

RELATIVE ENTROPY

Kummer Extension

References

Koch, H. "Kummer Extensions." §6.8 in *Number Theory: Algebraic Numbers and Functions.* Providence, RI: Amer. Math. Soc., pp. 195–199, 2000.

Kummer Group

A GROUP of LINEAR FRACTIONAL TRANSFORMATIONS which transform the arguments of Kummer solutions to the HYPERGEOMETRIC DIFFERENTIAL EQUATION into each other. Define

$$A(z) = 1 - z$$

$$B(z) = 1/z,$$

then the elements of the group are $\{I, A, B, AB, BA, ABA = BAB\}$..

Kummer Surface

The Kummer surfaces are a family of QUARTIC SURFACES given by the algebraic equation

$$(x^2+y^2+z^2-\mu^2 w^2)^2-\lambda pqrs=0, \tag{1}$$

where

$$\lambda \equiv \frac{3\mu^2-1}{3-\mu^2}, \tag{2}$$

p, q, r, and s are the TETRAHEDRAL COORDINATES

$$p=w-z-\sqrt{2}x \tag{3}$$

$$q=w-z+\sqrt{2}x \tag{4}$$

$$r=w+z+\sqrt{2}y \tag{5}$$

$$s=w+z-\sqrt{2}y, \tag{6}$$

and w is a parameter which, in the above plots, is set to $w=1$. The above plots correspond to $\mu^2=1/3$

$$(3x^2+3y^2+3z^2+1)^2=0, \tag{7}$$

(double sphere), 2/3, 1

$$x^4-2x^2y^2+y^4+4x^2z+4y^2z+4x^2z^2+4y^2z^2=0 \tag{8}$$

(ROMAN SURFACE), $\sqrt{2}$, $\sqrt{3}$

$$[(z-1)^2-2x^2][y^2-(z+1)^2]=0 \tag{9}$$

(four planes), 2, and 5. The case $0 \le \mu^2 \le 1/3$ corresponds to four real points.

The following table gives the number of ORDINARY DOUBLE POINTS for various ranges of μ^2, corresponding to the preceding illustrations.

$0 \le \mu^2 \le \frac{1}{3}$	4	12
$\mu^2=\frac{1}{3}$		
$\frac{1}{3} \le \mu^2 < 1$	4	12
$\mu^2=1$		
$1<\mu^2<3$	16	0
$\mu^2=3$		
$\mu^2>3$	16	0

The Kummer surfaces can be represented parametrically by hyperelliptic THETA FUNCTIONS. Most of the Kummer surfaces admit 16 ORDINARY DOUBLE POINTS, the maximum possible for a QUARTIC SURFACE. A special case of a Kummer surface is the TETRAHEDROID.

Nordstrand gives the implicit equations as

$$x^4+y^4+z^4-x^2-y^2-z^2-x^2y^2-x^2z^2-y^2z^2+1=0 \tag{10}$$

or

$$x^4+y^4+z^4+a(x^2+y^2+z^2)+b(x^2y^2+x^2z^2+y^2z^2) +cxyz-1=0. \tag{11}$$

Kummer's Conjecture

A conjecture concerning PRIMES.

Kummer's Differential Equation

CONFLUENT HYPERGEOMETRIC DIFFERENTIAL EQUATION

Kummer's Formulas

Kummer's first formula is

$${}_2F_1\left(\tfrac{1}{2}+m-k,\ -n;\ 2m+1;\ 1\right) = \frac{\Gamma(2m+1)\Gamma\left(m+\frac{1}{2}+k+n\right)}{\Gamma(m+\frac{1}{2}+k)\Gamma(2m+1+n)}, \tag{1}$$

where ${}_2F_1(a, b; c; z)$ is the HYPERGEOMETRIC FUNCTION with $m \neq -1/2, -1, -3/2, \ldots$, and $\Gamma(z)$ is the GAMMA FUNCTION. The identity can be written in the more symmetrical form as

$$ {}_2F_1(a, b; c; -1) = \frac{\Gamma\left(\frac{1}{2}b+1\right)\Gamma(b-a+1)}{\Gamma(b+1)\Gamma\left(\frac{1}{2}b-a+1\right)}, \quad (2) $$

where $a-b+c=1$ and b is a positive integer (Bailey 1935, p. 35; Petkovsek *et al.* 1996; Koepf 1998, p. 32; Hardy 1999, p. 106). If b is a negative integer, the identity takes the form

$$ {}_2F_1(a, b; c; -1) = 2\cos\left(\tfrac{1}{2}\pi b\right)\frac{\Gamma(|b|)\Gamma(b-a+1)}{\Gamma\left(\frac{1}{2}b-a+1\right)} \quad (3) $$

(Petkovsek *et al.* 1996).

Kummer's second formula is

$$ {}_1F_1\left(\tfrac{1}{2}+m;\ 2m+1;\ z\right) = M_{0,m}(z) $$
$$ = z^{m+1/2}\left[1+\sum_{p=1}^{\infty}\frac{z^{2p}}{2^{4p}p!(m+1)(m+2)\cdots(m+p)}\right], \quad (4) $$

where ${}_1F_1(a; b; z)$ is the CONFLUENT HYPERGEOMETRIC FUNCTION and $m \neq -1/2, -1, -3/2, \ldots$.

Kummer's Function

CONFLUENT HYPERGEOMETRIC FUNCTION

Kummer's Quadratic Transformation

A transformation of a HYPERGEOMETRIC FUNCTION,

$$ {}_2F_1\left(\alpha,\ \beta;\ 2\beta;\ \frac{4z}{(1+z)^2}\right) = (1+z)^{2\alpha}\,{}_2F_1\left(\alpha,\ \alpha+\tfrac{1}{2}-\beta;\ \beta+\tfrac{1}{2};\ z^2\right). $$

Kummer's Relation

An identity which relates HYPERGEOMETRIC FUNCTIONS,

$$ {}_2F_1\left(2a,\ 2b;\ a+b+\tfrac{1}{2};\ x\right) = {}_2F_1\left(a,\ b;\ a+b+\tfrac{1}{2},\ 4x(1-x)\right). $$

Kummer's Series

HYPERGEOMETRIC FUNCTION

Kummer's Series Transformation

Let $\Sigma_{k=0}^{\infty} a_k = a$ and $\Sigma_{k=0}^{\infty} c_k = c$ be convergent series such that

$$ \lim_{k\to\infty}\frac{a_k}{c_k} = \lambda \neq 0. $$

Then

$$ a = \lambda c + \sum_{k=0}^{\infty}\left(1-\lambda\frac{c_k}{a_k}\right)a_k. $$

Kummer's Test

Given a SERIES of POSITIVE terms u_i and a sequence of finite POSITIVE constants a_i, let

$$ \rho \equiv \lim_{n\to\infty}\left(a_n\frac{u_n}{u_{n+1}} - a_{n+1}\right). $$

1. If $\rho > 0$, the series converges.
2. If $\rho < 0$, the series diverges.
3. If $\rho = 0$, the series may converge or diverge.

The test is a general case of BERTRAND'S TEST, the ROOT TEST, GAUSS'S TEST, and RAABE'S TEST. With $a_n = n$ and $a_{n+1} = n+1$, the test becomes RAABE'S TEST.

Kummer's Theorem

The identity

$$ {}_2F_1(x, -x; x+n+1; -1) = \frac{\Gamma(x+n+1)\Gamma\left(\frac{1}{2}n+1\right)}{\Gamma\left(x+\frac{1}{2}n+1\right)\Gamma(n+1)}, $$

or equivalently

$$ {}_2F_1(\alpha, \beta; 1+\alpha-\beta; -1) = \frac{\Gamma(1+\alpha-\beta)\Gamma\left(1+\frac{1}{2}\alpha\right)}{\Gamma(1+\alpha)\Gamma\left(1+\frac{1}{2}\alpha-\beta\right)}, $$

where ${}_2F_1(a, b; c; z)$ is a HYPERGEOMETRIC FUNCTION and $\Gamma(z)$ is the GAMMA FUNCTION. This formula was first stated by Kummer (1836, p. 53).

Kuratowski Reduction Theorem

Every nonplanar graph is a SUPERGRAPH of an expansion of the UTILITY GRAPH $UG = K_{3,3}$ (i.e., the COMPLETE BIPARTITE GRAPH on two sets of three vertices) or the COMPLETE GRAPH K_5. This theorem was also proven earlier by Pontryagin (1927–1928), and later by Frink and Smith (1930). Kennedy *et al.* (1985) give a detailed history of the theorem, and there exists a generalization known as the ROBERTSON-SEYMOUR THEOREM.

Kuratowski's Closure-Component Problem

Let X be an arbitrary TOPOLOGICAL SPACE. Denote the CLOSURE of a SUBSET A of X by A^- and the COMPLEMENT of A by A'. Then at most 14 different SETS can be derived from A by repeated application of closure and complementation (Berman and Jordan 1975, Fife 1991). The problem was first proved by Kuratowski (1922) and popularized by Kelley (1955).

Kurschák's Tile

An attractive tiling of the SQUARE composed of two types of triangular tiles. It consists of 16 EQUILATERAL TRIANGLES and 32 15°-15°-150° ISOSCELES TRIANGLES arranged in the shape of a DODECAGON.

The composition of Kürschák's tile is motivated by drawing inward-pointing EQUILATERAL TRIANGLES on each side of a UNIT SQUARE and then connecting adjacent vertices to form a smaller SQUARE rotated 45° with respect to the original SQUARE. Joining the midpoints of the square together with the intersections of the EQUILATERAL TRIANGLES then gives a DODECAGON (Wells 1991) with CIRCUMRADIUS

$$R = \sin\left(\frac{\pi}{12}\right) = \tfrac{1}{4}(\sqrt{6}-\sqrt{2}).$$

See also DODECAGON, EQUILATERAL TRIANGLE, ISOSCELES TRIANGLE

Kurtosis

The degree of peakedness of a distribution, also called the "excess" or "excess coefficient." Kurtosis is a normalized form of the fourth CENTRAL MOMENT of a distribution. There are several flavors of kurtosis

commonly encountered, including FISHER KURTOSIS (denoted γ_2 or b_2) and PEARSON KURTOSIS (denoted β_2 or α_4). If not specifically qualified, then term "kurtosis" is generally taken to refer to FISHER KURTOSIS. A distribution with a high peak ($\gamma_2 > 0$) is called LEPTOKURTIC, a flat-topped curve ($\gamma_2 < 0$) is called PLATYKURTIC, and the normal distribution ($\gamma_2 = 0$) is called MESOKURTIC.

Let μ_i denote the ith CENTRAL MOMENT. Then the FISHER KURTOSIS is defined by

$$\gamma_2 \equiv \frac{\mu_4}{\mu_2^2} - 3 = \frac{\mu_4}{\sigma^4} - 3, \tag{1}$$

where σ^2 is the VARIANCE. Similarly, the PEARSON KURTOSIS is defined by

$$\beta_2 \equiv \frac{\mu_4}{\mu_2^2} = \frac{\mu_4}{\sigma^4}. \tag{2}$$

An ESTIMATOR for the FISHER KURTOSIS γ_2 is given by

$$\hat{g}_2 = \frac{k_4}{k_2^2}, \tag{3}$$

where the ks are K-STATISTIC. For a normal distribution, the variance of this estimator is

$$\operatorname{var}(g_2) \approx \frac{24}{N}. \tag{4}$$

The following table lists the FISHER KURTOSIS for a number of common distributions.

distribution	FISHER KURTOSIS
BERNOULLI DISTRIBUTION	$\frac{1}{1-p}+\frac{1}{p}-6$
BETA DISTRIBUTION	$\frac{6[a^3+a^2(1-2b)+b^2(1+b)-2ab(2+b)]}{ab(2+a+b)(3+a+b)}$
BINOMIAL DISTRIBUTION	$\frac{6p^2-6p+1}{np(1-p)}$
CHI-SQUARED DISTRIBUTION	$\frac{12}{r}$
EXPONENTIAL DISTRIBUTION	6
FISHER-TIPPETT DISTRIBUTION	$\frac{12}{5}$
GAMMA DISTRIBUTION	$\frac{6}{a}$
GEOMETRIC DISTRIBUTION	$5-p+\frac{1}{1-p}$
HALF-NORMAL DISTRIBUTION	$\frac{8(\pi-3)}{(\pi-2)^2}$
LAPLACE DISTRIBUTION	3
LOG NORMAL DISTRIBUTION	$e^{4S^2}+2e^{3S^2}+3e^{2S^2}-6$
MAXWELL DISTRIBUTION	$-\frac{4}{3}$
NEGATIVE BINOMIAL DISTRIBUTION	$\frac{6-p(6-p)}{r(1-p)}$
NORMAL DISTRIBUTION	0
POISSON DISTRIBUTION	$\frac{1}{\nu}$
RAYLEIGH DISTRIBUTION	$\frac{6\pi(4-\pi)-16}{(\pi-4)^2}$
STUDENT'S T-DISTRIBUTION	$\frac{6}{n-4}$
continuous UNIFORM DISTRIBUTION	$-\frac{6}{5}$
discrete UNIFORM DISTRIBUTION	$\frac{6(n^2+1)}{5(n^2-1)}$

L

L1-Norm

A VECTOR NORM defined for a VECTOR

$$\mathbf{x} = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{bmatrix},$$

with COMPLEX entries by

$$\|\mathbf{x}\|_1 = \sum_{r=1}^{n} |x_r|.$$

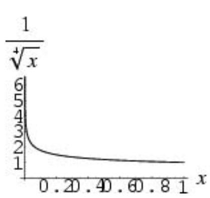
The vector norm $\|\mathbf{x}\|_1$ is implemented as `VectorNorm[`m`, 1]` in the *Mathematica* add-on package `LinearAlgebra'MatrixMultiplication'` (which can be loaded with the command `<<LinearAlgebra'`).

See also L1-SPACE, L2-NORM, L-INFINITY-NORM, VECTOR NORM

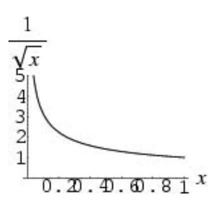
References

Gradshteyn, I. S. and Ryzhik, I. M. *Tables of Integrals, Series, and Products, 6th ed.* San Diego, CA: Academic Press, pp. 1114–125, 2000.

L1-Space



See also L1-NORM



L2-Function

Informally, an L^2-function is a function $f : X \to \mathbb{R}$ that is SQUARE INTEGRABLE, i.e.,

$$\|f\|^2 = \int_X |f|^2 \, d\mu$$

with respect to the MEASURE μ, exists (and is finite), in which case $\|f\|$ is its L2-NORM. Here X is a MEASURE SPACE and the integral is the LEBESGUE INTEGRAL. The collection of L^2 functions on X is called $L^2(X)$ (ell-two) of L2-SPACE, which is a HILBERT SPACE.

On the unit interval $(0, 1)$, the functions $f(x) = 1/x^p$ are in L^2 for $p < 1/2$. However, the function $f(x) = x^{-1/2}$ is not in L^2 since

$$\int_0^1 (x^{-1/2})^2 \, dx = \int_0^1 \frac{dx}{x}$$

does not exist.

More generally, there are L^2-COMPLEX FUNCTIONS obtained by replacing the ABSOLUTE VALUE of a REAL NUMBER in the definition with the NORM of the COMPLEX NUMBER. In fact, this generalizes to functions from a MEASURE SPACE X to any NORMED SPACE.

L^2-functions play an important role in many areas of ANALYSIS. They also arise in physics, and especially quantum mechanics, where probabilities are given as the integral of the absolute square of a wavefunction ψ. In this and in the context of energy density, L^2-functions arise due to the requirement that these quantities remain finite.

See also HILBERT SPACE, LEBESGUE INTEGRAL, LP-SPACE, L2-SPACE, MEASURE, MEASURE SPACE, SQUARE INTEGRABLE

L2-Inner Product

The L^2-inner product of two REAL FUNCTIONS f and g on a MEASURE SPACE X with respect to the MEASURE μ is given by

$$\langle f, g \rangle_{L^2} = \int_X fg \, d\mu,$$

sometimes also called the bracket product, where the symbol $\langle f, g \rangle$ are called ANGLE BRACKETS. If the functions are COMPLEX, the generalization of the HERMITIAN INNER PRODUCT

$$\int_X f\bar{g} \, d\mu$$

is used.

See also ANGLE BRACKET, BRA, HILBERT SPACE, KET, LEBESGUE INTEGRAL, L2-FUNCTION, L2-SPACE

L2-Norm

A VECTOR NORM defined for a VECTOR

$$\mathbf{x} = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{bmatrix}, \tag{1}$$

with COMPLEX entries by

$$\|\mathbf{x}\|_2 = \sqrt{\sum_{r=1}^{n} |x_r|^2}. \tag{2}$$

This discrete norm for a vector is sometimes called the l_2-norm, while the L_2-norm (denoted with an upper-case L) is reserved for application with a function $\phi(x)$, where it is defined by

$$\|\phi\|^2 \equiv \phi \cdot \phi \equiv \langle \phi | \phi \rangle \equiv \int |\phi(x)|^2 \, dx, \tag{3}$$

with $\langle f | g \rangle$ denoting an ANGLE BRACKET.

The L_2-norm $\|\mathbf{x}\|_2$ is also called the Euclidean norm, and is implemented as `VectorNorm[`m`, 2]` in the *Mathematica* add-on package `LinearAlgebra`MatrixMultiplication`` (which can be loaded with the command `<<LinearAlgebra``).

See also Angle Bracket, Complete Set of Functions, L1-Norm, L2-Space, L-Infinity-Norm, Parallelogram Law, Vector Norm

References

Gradshteyn, I. S. and Ryzhik, I. M. *Tables of Integrals, Series, and Products, 6th ed.* San Diego, CA: Academic Press, pp. 1114–125, 2000.

L2-Space

On a measure space X, the set of square integrable L2-functions is an L^2-space. Taken together with the L2-inner product (a.k.a. bracket product) with respect to a measure μ,

$$\langle f, g\rangle \equiv \int_X fg\, d\mu \tag{1}$$

the L^2-space forms a Hilbert space. The functions in an L^2-space satisfy

$$\langle \phi|\psi\rangle \equiv \int \bar{\psi}\phi\, dx \tag{2}$$

and

$$\overline{\langle \phi|\psi\rangle} = \langle \psi|\phi\rangle \tag{3}$$

$$\langle \phi|\lambda_1\psi_1 + \lambda_2\psi_2\rangle = \lambda_1\langle \phi|\psi_1\rangle + \lambda_2\langle \phi|\psi_2\rangle \tag{4}$$

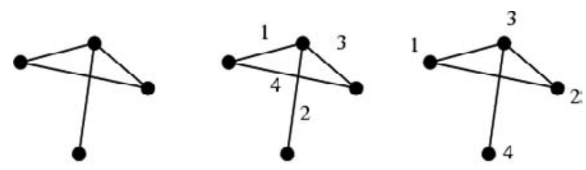
$$\langle \lambda_1\phi_1 + \lambda_2\phi_2|\psi\rangle = \bar{\lambda}_1\langle \phi_1|\psi\rangle + \bar{\lambda}_2\langle \phi_2|\psi\rangle \tag{5}$$

$$\langle \psi|\psi\rangle \in \mathbb{R} \geq 0 \tag{6}$$

$$|\langle \psi_1|\psi_2\rangle|^2 \leq \langle \psi_1|\psi_1\rangle\langle \psi_2|\psi_2\rangle. \tag{7}$$

The inequality (7) is called Schwarz's inequality.

The basic example is when $X = \mathbb{R}$ with Lebesgue measure. Another important example is when X is the positive integers, in which case it is denoted as l^2, or "little ell-two." These are the square summable series.



Strictly speaking, L^2-space really consists of equivalence classes of functions. Two functions represent the same L^2-function if the set where they differ has measure zero. It is not hard to see that this makes $\langle f, g\rangle$ an inner product, because $\langle f, f\rangle = 0$ if and only if $f = 0$ almost everywhere. A good way to think of an L^2-function is as a density function, so only its integral on sets with positive measure matter.

In practice, this does not cause much trouble, except that some care has to be taken with boundary conditions in differential equations. The problem is that for any particular point p, the value $f(p)$ isn't well defined for an L^2-function f.

If an L^2-function in Euclidean space can be represented by a continuous function f, then f is the only continuous representative. In such a case, it is not harmful to consider the L^2-function as the continuous function f. Also, it is often convenient to think of $L^2(\mathbb{R}^n)$ as the completion of the continuous functions with respect to the L2-norm.

Labeled Graph

unlabeled graph *edge-labeled graph* *vertex-labeled graph*

A labeled graph $G = (V, E)$ is a finite series of vertices V with a set of edges E of 2-subsets of V. Given a vertex set $V_n = \{1, 2, \ldots, n\}$, the number of vertex-labeled graphs is given by $2^{n(n-1)/2}$. Two graphs G and H with vertices $V_n = \{1, 2, \ldots, n\}$ are said to be isomorphic if there is a permutation p of V_n such that $\{u, v\}$ is in the set of edges $E(G)$ iff $\{p(u), p(v)\}$ is in the set of edges $E(H)$.

The term "labeled graph" when used without qualification means a graph with each node labeled differently (but arbitrarily), so that all nodes are considered distinct for purposes of enumeration. The *total* number of (not necessarily connected) labeled n-node graphs is given 1, 2, 8, 64, 1024, 32768, ... (Sloane's A006125; illustrated above), and the numbers of connected labeled graphs on n-nodes are given by the logarithmic transform of the preceding sequence, 1, 1, 4, 38, 728, 26704, ... (Sloane's A001187; Sloane and Plouffe 1995, p. 19).

Labeled Tree

A TREE with its nodes labeled. The number of labeled trees on n nodes is n^{n-2}, the first few values of which are 1, 1, 3, 16, 125, 1296, ... (Sloane's A000272). Cayley (1889) provided the first proof of the number of labeled trees (Skiena 1990, p. 151), and a constructive proof was subsequently provided by Prüfer (1918). Prüfer's result gives an encoding for labeled trees known as PRÜFER CODE (indicated underneath the trees above, where the trees are depicted using an embedding with root at the node labeled 1).

The probability that a random labeled tree is CENTERED is asymptotically equal to 1/2 (Szekeres 1983; Skiena 1990, p. 167).

Lagrange Bracket

Let F and G be infinitely differentiable functions of x, u, and p. Then the Lagrange bracket is defined by

$$[F,\ G] = \sum_{v=1}^{n} \left[\frac{\partial F}{\partial p_v} \left(\frac{\partial G}{\partial x_p} + p_v \frac{\partial G}{\partial u} \right) - \frac{\partial G}{\partial p_v} \left(\frac{\partial F}{\partial x_v} + p_v \frac{\partial F}{\partial u} \right) \right]. \qquad (1)$$

The Lagrange bracket satisfies

$$[F,\ G] = -[G,\ F] \qquad (2)$$

$$[[F,\ G],\ H] + [[G,\ H],\ F] + [[H,\ F],\ G] = \frac{\partial F}{\partial u}[G,\ H] + \frac{\partial G}{\partial u}[H,\ F] + \frac{\partial H}{\partial u}[F,\ G]. \qquad (3)$$

If F and G are functions of x and p only, then the Lagrange bracket $[F,\ G]$ collapses the POISSON BRACKET $(F,\ G)$.

Lagrange-Bürmann Expansion

LAGRANGE INVERSION THEOREM

Lagrange-Bürmann Theorem

LAGRANGE INVERSION THEOREM

Lagrange Expansion

Let $y = f(x)$ and $y_0 = f(x_0)$ where $f'(x_0) \neq 0$, then

$$x = x_0 + \sum_{k=1}^{\infty} \frac{(y-y_0)^k}{k!} \left\{ \frac{d^{k-1}}{dx^{k-1}} \left[\frac{x-x_0}{f(x)-y_0} \right]^k \right\}_{x=x_0}$$

$$g(x) = g(x_0) + \sum_{k=1}^{\infty} \frac{(y-y_0)^k}{k!} \times \left\{ \frac{d^{k-1}}{dx^{k-1}} \left[g'(x) \left(\frac{x-x_0}{f(x)-y_0} \right)^k \right] \right\}_{x=x_0}.$$

Expansions of this form were first considered by Lagrange (1770; Lagrange 1868, pp. 680–93).

Lagrange Interpolating Polynomial

The Lagrange interpolating polynomial is the POLYNOMIAL of degree $n-1$ which passes through the n points $y_1 = f(x_1)$, $y_2 = f(x_2)$, ..., $y_n = f(x_n)$. It is given by

$$P(x) = \sum_{j=1}^{n} P_j(x), \qquad (1)$$

where

$$P_j(x) = \prod_{\substack{k=1 \\ k \neq j}}^{n} \frac{x - x_k}{x_j - x_k} y_j. \qquad (2)$$

Written explicitly,

$$P(x) = \frac{(x-x_2)(x-x_3)\cdots(x-x_n)}{(x_1-x_2)(x_1-x_3)\cdots(x_1-x_n)} y_1 + \frac{(x-x_1)(x-x_3)\cdots(x-x_n)}{(x_2-x_1)(x_2-x_3)\cdots(x_2-x_n)} y_2 + \cdots + \frac{(x-x_1)(x-x_2)\cdots(x-x_{n-1})}{(x_n-x_1)(x_n-x_2)\cdots(x_n-x_{n-1})} y_n. \qquad (3)$$

The formula was first published by Waring (1779), rediscovered by Euler in 1783, and published by Lagrange in 1795 (Jeffreys and Jeffreys 1988).

For $n = 3$ points,

$$P(x) = \frac{(x-x_2)(x-x_3)}{(x_1-x_2)(x_1-x_3)} y_1 + \frac{(x-x_1)(x-x_3)}{(x_2-x_1)(x_2-x_3)} y_2 + \frac{(x-x_1)(x-x_2)}{(x_3-x_1)(x_3-x_2)} y_3 \qquad (4)$$

$$P'(x) = \frac{2x - x_2 - x_3}{(x_1 - x_2)(x_1 - x_3)} y_1 + \frac{2x - x_1 - x_3}{(x_2 - x_1)(x_2 - x_3)} y_2 + \frac{2x - x_1 - x_2}{(x_3 - x_1)(x_3 - x_2)} y_3 \quad (5)$$

Note that the function $P(x)$ passes through the points (x_i, y_i), as can be seen for the case $n = 3$,

$$P(x_1) = \frac{(x_1 - x_2)(x_1 - x_3)}{(x_1 - x_2)(x_1 - x_3)} y_1 + \frac{(x_1 - x_1)(x_1 - x_3)}{(x_2 - x_1)(x_2 - x_3)} y_2 + \frac{(x_1 - x_1)(x_1 - x_2)}{(x_3 - x_1)(x_3 - x_2)} y_3 = y_1 \quad (6)$$

$$P(x_2) = \frac{(x_2 - x_2)(x_2 - x_3)}{(x_1 - x_2)(x_1 - x_3)} y_1 + \frac{(x_2 - x_1)(x_2 - x_3)}{(x_2 - x_1)(x_2 - x_3)} y_2 + \frac{(x_2 - x_1)(x_2 - x_2)}{(x_3 - x_1)(x_3 - x_2)} y_3 = y_2 \quad (7)$$

$$P(x_3) = \frac{(x_3 - x_2)(x_3 - x_3)}{(x_1 - x_2)(x_1 - x_3)} y_1 + \frac{(x_3 - x_1)(x_3 - x_3)}{(x_2 - x_1)(x_2 - x_3)} y_2 + \frac{(x_3 - x_1)(x_3 - x_2)}{(x_3 - x_1)(x_3 - x_2)} y_3 = y_3. \quad (8)$$

Generalizing to arbitrary n,

$$P(x_j) = \sum_{k=1}^{n} P_k(x_j) = \sum_{k=1}^{n} \delta_{jk} y_k = y_j. \quad (9)$$

The Lagrange interpolating polynomials can also be written using what Szego (1975) called Lagrange's fundamental interpolating polynomials. Let

$$\pi(x) \equiv \prod_{k=1}^{n} (x - x_k), \quad (10)$$

$$\pi(x_j) \equiv \prod_{k=1}^{n} (x_j - x_k), \quad (11)$$

$$\pi'(x_j) = \left[\frac{d\pi}{dx}\right]_{x=x_j} = \prod_{\substack{k=1 \\ k \neq j}}^{n} (x_j - x_k) \quad (12)$$

so that $\pi(x)$ is an nth degree POLYNOMIAL with zeros at $x_1, ..., x_n$. Then define the fundamental polynomials by

$$\pi_\nu(x) = \frac{\pi(x)}{\pi'(x_\nu)(x - x_\nu)}, \quad (13)$$

which satisfy

$$\pi_\nu(x_\mu) = \delta_{\nu\mu}, \quad (14)$$

where $\delta_{\nu\mu}$ is the KRONECKER DELTA. Now let $y_1 = P(x_1)$, ..., $y_n = P(x_n)$, then the expansion

$$P(x) = \sum_{k=1}^{n} \pi_k(x) y_k = \sum_{k=1}^{n} \frac{\pi(x)}{(x - x_k)\pi'(x_k)} y_k \quad (15)$$

gives the unique Lagrange interpolating polynomial assuming the values y_k at x_k. More generally, let $d\alpha(x)$ be an arbitrary distribution on the interval $[a, b]$, $\{p_n(x)\}$ the associated ORTHOGONAL POLYNOMIALS, and $l_1(x)$, ..., $l_n(x)$ the fundamental POLYNOMIALS corresponding to the set of zeros of a polynomial $P_n(x)$. Then

$$\int_a^b l_\nu(x) l_\mu(x) \, d\alpha(x) = \lambda_\mu \delta_{\nu\mu} \quad (16)$$

for $\nu, \mu = 1, 2, ..., n$, where λ_ν are CHRISTOFFEL NUMBERS.

Lagrange interpolating polynomials give no error estimate. A more conceptually straightforward method for calculating them is NEVILLE'S ALGORITHM.

Lagrange Interpolation

LAGRANGE INTERPOLATING POLYNOMIAL

Lagrange Inversion Theorem

Let z be defined as a function of w in terms of a parameter α by

$$z = w + \alpha\phi(z).$$

Then any function of z can be expressed as a POWER SERIES in α which converges for sufficiently small α and has the form

$$F(z) = F(w) + \frac{\alpha}{1}\,\phi(w)F'(w) + \frac{\alpha^2}{1\cdot 2}\,\frac{\partial}{\partial w}\{[\phi(w)]^2F'(w)\}$$

$$+\ldots+\frac{\alpha^{n+1}}{(n+1)!}\,\frac{\partial^n}{\partial w^n}\{[\phi(w)]^{n+1}F'(w)\}+\ldots.$$

Lagrange Multiplier

Used to find the EXTREMUM of $f(x_1, x_2, \ldots, x_n)$ subject to the constraint $g(x_1, x_2, \ldots, x_n) = C$, where f and g are functions with continuous first PARTIAL DERIVATIVES on the OPEN SET containing the curve $g(x_1, x_2, \ldots, x_n) = 0$, and $\nabla g \neq 0$ at any point on the curve (where ∇ is the GRADIENT). For an EXTREMUM to exist,

$$df = \frac{\partial f}{\partial x_1}\,dx_1 + \frac{\partial f}{\partial x_2}\,dx_2 + \ldots + \frac{\partial f}{\partial x_n}\,dx_n = 0. \qquad (1)$$

But we also have

$$dg = \frac{\partial g}{\partial x_1}\,dx_1 + \frac{\partial g}{\partial x_2}\,dx_2 + \ldots + \frac{\partial g}{\partial x_n}\,dx_n = 0. \qquad (2)$$

Now multiply (2) by the as yet undetermined parameter λ and add to (1),

$$\left(\frac{\partial f}{\partial x_1} + \lambda\,\frac{\partial q}{\partial x_1}\right)dx_1 + \left(\frac{\partial f}{\partial x_2} + \lambda\,\frac{\partial q}{\partial x_2}\right)dx_2$$

$$+\ldots+\left(\frac{\partial f}{\partial x_n} + \lambda\,\frac{\partial q}{\partial x_n}\right)dx_n = 0. \qquad (3)$$

Note that the differentials are all independent, so we can set any combination equal to 0, and the remainder must still give zero. This requires that

$$\frac{\partial f}{\partial x_k} + \lambda\,\frac{\partial g}{\partial x_k} = 0 \qquad (4)$$

for all $k = 1, \ldots, n$. The constant λ is called the Lagrange multiplier. For multiple constraints, $g_1 = 0$, $g_2 = 0$, ...,

$$\nabla f = \lambda_1 \nabla g_1 + \lambda_2 \nabla g_2 + \ldots. \qquad (5)$$

Lagrange Number (Diophantine Equation)

Given a FERMAT DIFFERENCE EQUATION (a quadratic DIOPHANTINE EQUATION)

$$x^2 - r^2y^2 = 4$$

with r a QUADRATIC SURD, assign to each solution $x|y$ the Lagrange number

$$z \equiv \tfrac{1}{2}(x + yr).$$

The product and quotient of two Lagrange numbers are also Lagrange numbers. Furthermore, every Lagrange number is a POWER of the smallest Lagrange number with an integral exponent.

See also PELL EQUATION

References

Dörrie, H. *100 Great Problems of Elementary Mathematics: Their History and Solutions.* New York: Dover, pp. 94–5, 1965.

Lagrange Number (Rational Approximation)

HURWITZ'S IRRATIONAL NUMBER THEOREM gives the best rational approximation possible for an arbitrary irrational number $-\beta$ as

$$\phi$$

The $\sqrt{8}$ are called Lagrange numbers and get steadily larger for each "bad" set of irrational numbers which is excluded.

n	Exclude	$\sqrt{8}$

1	none	$\sqrt{2}$
2	$\frac{\sqrt{221}}{5}$	$\sqrt{9-\frac{4}{3}}$,
3	m	$f(x)=f(x_0)+(x-x_0)f'(x_0)+\frac{(x-x_0)^2}{2!}f''(x_0)+\ldots$

Lagrange numbers are OF THE FORM

$$+\frac{(x-x_0)^n}{n!}f^{(n)}(x_0)+R_n,$$

where m is a MARKOV NUMBER. The Lagrange numbers form a SPECTRUM called the LAGRANGE SPECTRUM.

See also HURWITZ'S IRRATIONAL NUMBER THEOREM, IRRATIONALITY MEASURE, LIOUVILLE'S APPROXIMATION THEOREM, MARKOV NUMBER, ROTH'S THEOREM, SPECTRUM SEQUENCE, THUE-SIEGEL-ROTH THEOREM

Lagrange Polynomial

LAGRANGE INTERPOLATING POLYNOMIAL

Lagrange Remainder

Given a TAYLOR SERIES

$$f(x)=f(x_0)+(x-x_0)f'(x_0)+\frac{(x-x_0)^2}{2!}f''(x_0)+\ldots$$

$$+\frac{(x-x_0)^n}{n!}f^{(n)}(x_0)+R_n, \quad (1)$$

the error R_n after n terms is given by

$$R_n=\int_{x_0}^{x} f^{(n+1)}(t)\frac{(x-t)^n}{n!}\,dt. \quad (2)$$

Using the MEAN-VALUE THEOREM, this can be bounded by

$$R_n=\frac{f^{(n+1)}(x^*)}{(n+1)!}(x-x_0)^{n+1} \quad (3)$$

for some $x^*\in(x_0, x)$ (Abramowitz and Stegun 1972, p. 880).

Note that the Lagrange remainder R_n is also sometimes taken to refer to the remainder when terms up to the $(n-1)$st power are taken in the TAYLOR SERIES, and that a notation in which $h\to x-x_0$, $x^*\to a+\theta h$, and $x-x^*\to 1-\theta$ is sometimes used (Blumenthal 1926; Whittaker and Watson 1990, pp. 95–6).

Lagrange's Four-Square Theorem

A theorem also known as BACHET'S CONJECTURE which was stated but not proven by Diophantus. It states that every POSITIVE INTEGER can be written as the SUM of at most four SQUARES. Although the theorem was proved by Fermat using infinite descent, the proof was suppressed. Euler was unable to prove the theorem. The first published proof was given by Lagrange in 1770 and made use of the EULER FOUR-SQUARE IDENTITY.

Lagrange proved that $g(2)=4$, where 4 may be reduced to 3 except for numbers OF THE FORM $4^n(8k+7)$, as proved by Legendre in 1798 (Nagell 1951, p. 194; Wells 1986, pp. 48 and 56; Hardy 1999, p. 12; Savin 2000).

Lagrange's Group Theorem

This entry contributed by NICOLAS BRAY

Also known as Lagrange's lemma. The most general form of Lagrange's theorem states that for a GROUP G, a SUBGROUP H of G, and a subgroup K of H, $(G:K)=(G:H)(H:K)$, where the products are taken as cardinalities (thus the theorem holds even for INFINITE GROUPS) and (G_H) denotes the INDEX. A frequently stated corollary (which follows from taking $K=\{e\}$, where e is the IDENTITY ELEMENT) is that the order of G is equal to the product of the order of H and the INDEX of H.

The corollary is easily proven in the case of G being a FINITE GROUP, as the LEFT COSETS of H form a partition of G, and so the number of blocks in the partition (which is $(G:H)$) multiplied by the number of elements in each partition (which is just the order of H).

For a FINITE GROUP G, this corollary gives that the order of H must divide the order of G. Then, because the order of an element x of G is the order of the cyclic subgroup generated by x, we must have that the order of any element of G divides the order of G.

The converse of Lagrange's theorem is not, in general, true (Gallian 1993, 1994).

Lagrange's Identity

The algebraic identity

$$\left(\sum_{k=1}^{n} a_k b_k\right)^2 = \left(\sum_{k=1}^{n} a_k^2\right)\left(\sum_{k=1}^{n} b_k^2\right) - \sum_{1\le k<j\le n} (a_k b_j - a_j b_k)^2 \quad (1)$$

(Mitrinovic 1970, p. 41). In determinant form,

$$(\mathbf{a}_1\times\cdots\times\mathbf{a}_{n-1})\cdot(\mathbf{b}_1\times\cdots\times\mathbf{b}_{n-1}) = \begin{vmatrix} \mathbf{a}_1\cdot\mathbf{b}_1 & \cdots & \mathbf{a}_1\cdot\mathbf{b}_{n-1} \\ \vdots & \ddots & \vdots \\ \mathbf{a}_{n-1}\cdot\mathbf{b}_1 & \cdots & \mathbf{a}_{n-1}\cdot\mathbf{b}_{n-1} \end{vmatrix}, \quad (2)$$

where $|\mathsf{A}|$ is the DETERMINANT of A. Lagrange's identity is a special case of the BINET-CAUCHY IDENTITY, and CAUCHY'S INEQUALITY in n-D follows from it. It can be coded in *Mathematica* as follow.

```
<<DiscreteMath`Combinatorica`;
CauchyLagrangeId[n_] := Module[
   {aa = Array[a, n], bb = Array[b, n]},
   Plus @@ (aa^2)Plus @@ (bb^2) ==
   Plus @@ ((a[#1]b[#2] - a[#2]b[#1])^2 & @@@
    KSubsets[Range[n], 2]) +
```

```
  (aa.bb)^2
]
```

Plugging in gives the $n=2$ and $n=3$ identities

$$(a_1^2+a_2^2)(b_1^2+b_2^2)=(a_1b_1+a_2b_2)^2+(a_1b_2-a_2b_1)^2 \quad (3)$$

$$(a_1^2+a_2^2+a_3^2)(b_1^2+b_2^2+b_3^2)=(a_1b_1+a_2b_2+a_3b_3)^2$$
$$+[(a_1b_2-a_2b_1)^2+(a_1b_3-a_3b_1)^2+(a_2b_3-a_3b_2)^2]. \quad (4)$$

Lagrangian Coefficient

coefficients which appear in Lagrange interpolating polynomials where the points are equally spaced along the abscissa.

Lagrangian Derivative

Convective Derivative

Laguerre Differential Equation

$$xy''+(1-x)y'+\lambda y=0. \quad (1)$$

The Laguerre differential equation is a special case of the more general "associated Laguerre differential equation"

$$xy''+(\nu+1-x)y'+\lambda y=0 \quad (2)$$

(Iyanaga and Kawada 1980, p. 1481; Zwillinger 1997, p. 124) with $\nu=0$. The general solution is

$$t=C_1U(-\lambda,\ 1+\nu,\ x)+C_2L_\lambda^\nu(x), \quad (3)$$

where $U(a,\ b,\ x)$ is a confluent hypergeometric function of the first kind and $L_\lambda^\nu(x)$ is an associated Laguerre polynomial.

Note that in the special case $\lambda=0$, the associated Laguerre differential equation is of the form

$$y''(x)+P(x)y'(x)=0, \quad (4)$$

so the solution can be found using an integrating factor

$$\mu=\exp\left(\int P(x)\,dx\right)=\exp\left(\int \frac{\nu+1-x}{x}\,dx\right)$$
$$=\exp[(\nu+1)\ln x-x]=x^{\nu+1}e^{-x}, \quad (5)$$

as

$$y=C_1\int\frac{dx}{\mu}+C_2=C_1\int\frac{e^x}{x^{\nu+1}}\,dx+C_2 \quad (6)$$
$$=C_2-C_1x^{-\nu}E_{1+\nu}(-x), \quad (7)$$

where $E_n(x)$ is the E_n-function.

The associated Laguerre differential equation has a regular singular point at 0 and an irregular singularity at ∞. It can be solved using a series expansion,

$$x\sum_{n=2}^{\infty}n(n-1)a_nx^{n-2}+(\nu+1)\sum_{n=1}^{\infty}na_nx^{n-1}$$
$$-x\sum_{n=1}^{\infty}na_nx^{n-1}+\lambda\sum_{n=0}^{\infty}a_nx^n=0 \quad (8)$$

$$\sum_{n=2}^{\infty}n(n-1)a_nx^{n-1}+(\nu+1)\sum_{n=1}^{\infty}na_nx^{n-1}$$
$$-\sum_{n=1}^{\infty}na_nx^n+\lambda\sum_{n=0}^{\infty}a_nx^n=0 \quad (9)$$

$$\sum_{n=1}^{\infty}(n+1)na_{n+1}x^n+(\nu+1)\sum_{n=0}^{\infty}(n+1)a_{n+1}x^n$$
$$-\sum_{n=1}^{\infty}na_nx^n+\lambda\sum_{n=0}^{\infty}a_nx^n=0 \quad (10)$$

$$[(n+1)a_1+\lambda a_0] + \sum_{n=1}^{\infty}\{[(n+1)n+(\nu+1)(n+1)]a_{n+1}-na_n+\lambda a_n\}x^n = 0 \quad (11)$$

$$[(n+1)a_1+\lambda a_0] + \sum_{n=1}^{\infty}[(n+1)(n+\nu+1)a_{n+1}+(\lambda-n)a_n]x^n = 0. \quad (12)$$

This requires

$$a_1 = -\frac{\lambda}{\nu+1}\,a_0 \quad (13)$$

$$a_{n+1} = \frac{n-\lambda}{(n+1)(n+\nu+1)}\,a_n \quad (14)$$

for $n > 1$. Therefore,

$$a_{n+1} = \frac{n-\lambda}{(n+1)(n+\nu+1)}\,a_n \quad (15)$$

for $n = 1, 2, \ldots$, so

$$y = a_0\left[1-\frac{\lambda}{\nu+1}\,x-\frac{\lambda(1-\lambda)}{2(\nu+1)(\nu+2)}\,x^2 - \frac{\lambda(1-\lambda)(2-\lambda)}{2\cdot 3(\nu+1)(\nu+2)(\nu+3)}+\cdots\right]. \quad (16)$$

If λ is a POSITIVE INTEGER, then the series terminates and the solution is a POLYNOMIAL, known as an associated LAGUERRE POLYNOMIAL (or, if $\nu=0$, simply a LAGUERRE POLYNOMIAL).

See also LAGUERRE POLYNOMIAL

Laguerre-Gauss Quadrature

Also called GAUSS-LAGUERRE QUADRATURE or LAGUERRE QUADRATURE. A GAUSSIAN QUADRATURE over the interval $[0, \infty)$ with WEIGHTING FUNCTION $W(x)=e^{-x}$ (Abramowitz and Stegun 1972, p. 890). The ABSCISSAS for quadrature order n are given by the ROOTS of the LAGUERRE POLYNOMIALS $L_n(x)$. The weights are

$$w_i = -\frac{A_{n+1}\gamma_n}{A_n L_n'(x_i)L_{n+1}(x_i)} = \frac{A_n}{A_{n-1}}\,\frac{\gamma_{n-1}}{L_{n-1}(x_i)L_n'(x_i)}, \quad (1)$$

where A_n is the COEFFICIENT of x^n in $L_n(x)$. For LAGUERRE POLYNOMIALS,

$$A_n = \frac{(-1)^n}{n!}, \quad (2)$$

where $n!$ is a FACTORIAL, so

$$\frac{A_{n+1}}{A_n} = -\frac{1}{n+1} \quad (3)$$

$$\frac{A_n}{A_{n-1}} = -\frac{1}{n}. \quad (4)$$

Additionally,

$$\gamma_n = \int_0^\infty W(x)[L_n(x)]^2\,dx = 1, \quad (5)$$

so

$$w_i = \frac{1}{(n+1)L_n'(x_i)L_{n+1}(x_i)} = -\frac{1}{nL_{n-1}(x_i)L_n'(x_i)}. \quad (6)$$

Using the RECURRENCE RELATION

$$xL_n'(x) = nL_n(x) - nL_{n-1}(x) = (x-n-1)L_n(x)+(n+1)L_{n+1}(x) \quad (7)$$

which, since x_i is a root of $L_n(x)$, gives

$$nL_n(x) = (x-n-1)L_n(x) = 0, \quad (8)$$

so (7) becomes

$$x_i L_n'(x_i) = -nL_{n-1}(x_i) = (n+1)L_{n+1}(x_i) \quad (9)$$

gives

$$w_i = \frac{1}{x_i[L_n'(x_i)]^2} = \frac{x_i}{(n+1)^2[L_{n+1}(x_i)]^2}. \quad (10)$$

The error term is

$$E = \frac{(n!)^2}{(2n)!}\,f^{(2n)}(\xi) \quad (11)$$

(Abramowitz and Stegun 1972, p. 890).

Beyer (1987) gives a table of ABSCISSAS and weights up to $n=6$.

n	x_i	w_i
2	0.585786	0.853553
	3.41421	0.146447
3	0.415775	0.711093
	2.29428	0.278518
	6.28995	0.0103893
4	0.322548	0.603154
	1.74576	0.357419
	4.53662	0.0388879

	9.39507	0.000539295
5	0.26356	0.521756
	1.4134	0.398667
	3.59643	0.0759424
	7.08581	0.00361176
	12.6408	0.00002337

The ABSCISSAS and weights can be computed analytically for small n.

n	x_i	w_i
2	$2-\sqrt{2}$	$\frac{1}{4}(2+\sqrt{2})$
	$2+\sqrt{2}$	$\frac{1}{4}(2-\sqrt{2})$

For the associated Laguerre polynomial $L_n^\beta(x)$ with WEIGHTING FUNCTION $w(x)=x^\beta e^{-x}$,

$$A_n=\frac{(-1)^n}{n!} \tag{12}$$

is the coefficient of x^n in $L_n^\beta(x)$ and

$$\gamma_n=\int_0^\infty x^\beta e^{-x}[L_n^\beta(x)]^2\,dx=\frac{\Gamma(n+\beta+1)}{n!}, \tag{13}$$

where $\Gamma(z)$ is the GAMMA FUNCTION. The weights are then

$$w_i=\frac{\Gamma(n+\beta)x_i}{n!(n+\beta)[L_{n-1}^\beta(x_i)]^2}=\frac{\Gamma(n+\beta+1)x_i}{n!(n+1)^2[L_{n+1}^\beta(x_i)]^2}, \tag{14}$$

and the error term is

$$E_n=\frac{n!\Gamma(n+\beta+1)}{(2n)!}f^{(2n)}(\xi). \tag{15}$$

LaguerreL

LAGUERRE POLYNOMIAL

Laguerre Polynomial

Solutions $L_n(x)$ to the LAGUERRE DIFFERENTIAL EQUATION with $\nu=0$ are called Laguerre polynomials, illustrated above for $x\in[0,\ 1]$ and $n=1,\ 2,\ ...,\ 5$.
The Rodrigues formula for the Laguerre polynomials is

$$L_n(x)=\frac{e^x}{n!}\frac{d^n}{dx^n}(x^n e^{-x}) \tag{1}$$

and the GENERATING FUNCTION for Laguerre polynomials is

$$g(x,\ z)=\frac{\exp\left(-\frac{xz}{1-z}\right)}{1-z}=1+(-x+1)z$$
$$+\left(\tfrac{1}{2}x^2-2x+1\right)z^2+\left(-\tfrac{1}{6}x^3+\tfrac{3}{2}x^2-3x+1\right)z^3+\ldots. \tag{2}$$

A CONTOUR INTEGRAL is given by

$$L_n(x)=\frac{1}{2\pi i}\int\frac{e^{-xz/(1-z)}}{(1-z)z^{n+1}}\,dz. \tag{3}$$

The Laguerre polynomials satisfy the RECURRENCE RELATIONS

$$(n+1)L_{n+1}(x)=(2n+1-x)L_n(x)-nL_{n-1}(x) \tag{4}$$

(Petkovsek *et al.* 1996) and

$$xL_n'(x)=nL_n(x)-nL_{n-1}(x). \tag{5}$$

The first few Laguerre polynomials are

$$L_0(x)=1$$

$$L_1(x)=-x+1$$

$$L_2(x)=\tfrac{1}{2}(x^2-4x+2)$$

$$L_3(x)=\tfrac{1}{6}(-x^3+9x^2-18x+6).$$

Solutions to the associated LAGUERRE DIFFERENTIAL EQUATION with $\nu\neq 0$ are called associated Laguerre polynomials $L_n^k(x)$ or, in older literature, Sonine

polynomials (Sonine 1880, p. 41; Whittaker and Watson 1990, p. 352). In terms of the unassociated Laguerre polynomials,

$$L_n(x) = L_n^0(x). \tag{6}$$

The Rodrigues formula for the associated Laguerre polynomials is

$$L_n^k(x) = \frac{e^x x^{-k}}{n!} \frac{d^n}{dx^n}(e^{-x}x^{n+k}) \tag{7}$$

$$= (-1)^k \frac{d^k}{dx^k}[L_{n+k}(x)] \tag{8}$$

$$= \frac{(-1)^n x^{-(k+1)/2}}{n!} e^{x/2} W_{k/2+n+1/2,\ k/2}(x) \tag{9}$$

$$= \sum_{m=0}^{n} (-1)^m \frac{(n+k)!}{(n-m)!(k+m)!m!} x^m, \tag{10}$$

where $W_{k,\ m}(x)$ is a WHITTAKER FUNCTION. The associated Laguerre polynomials are a SHEFFER SEQUENCE with

$$g(t) = (1-t)^{-k-1} \tag{11}$$

$$f(t) = \frac{t}{t-1}, \tag{12}$$

giving the GENERATING FUNCTION

$$g(x,\ z) = \frac{\exp\left(-\frac{zz}{1-z}\right)}{(1-z)^{k+1}}$$

$$= 1 + (k+1-x)z + \tfrac{1}{2}[x^2 - 2(k+2)x + (k+1)(k+2)]z^2 + \ldots. \tag{13}$$

where the usual factor of $n!$ in the denominator has been suppressed (Roman 1984, p. 31). Many interesting properties of the associated Laguerre polynomials follow from the fact that $f^{-1}(t) = f(t)$ (Roman 1984, p. 31).

The associated Laguerre polynomials are given explicitly by the formula

$$L_n^{(k)}(x) = \frac{1}{n!} \sum_{i=0}^{n} \frac{n!}{i!} \binom{k+n}{n-i,} (-x)^i, \tag{14}$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT, and have Sheffer identity

$$\frac{1}{n!} L_n^{(k)}(x+y) = \sum_{i=0}^{n} \binom{n}{i} \frac{1}{i!} L_i^{(k)}(x) \frac{1}{(n-i)!} L_{n-i}^{(-1)}(y) \tag{15}$$

(Roman 1984, p. 31). The associated Laguerre polynomial can also be written as

$$L_n^{(k)}(x) = \frac{(k+1)_n}{n!} {}_1F_1(-n;\ k+1;\ x), \tag{16}$$

where $(a)_n$ is the POCHHAMMER SYMBOL and ${}_1F_1(a;\ b;\ x)$ is a CONFLUENT HYPERGEOMETRIC FUNCTION (Koekoek and Swarttouw 1998).

The associated Laguerre polynomials are orthogonal over $[0,\ \infty)$ with respect to the WEIGHTING FUNCTION $x^n e^{-x}$.

$$\int_0^\infty e^{-x} x^k L_n^k(x) L_m^k(x)\, dx = \frac{(n+k)!}{n!} \delta_{mn}, \tag{17}$$

where δ_{mn} is the KRONECKER DELTA. They also satisfy

$$\int_0^\infty e^{-x} x^{k+1} [L_n^k(x)]^2\, dx = \frac{(n+k)!}{n!}(2n+k+1). \tag{18}$$

RECURRENCE RELATIONS include

$$\sum_{v=0}^{n} L_v^{(k)}(x) = L_n^{(k+1)}(x) \tag{19}$$

and

$$L_n^{(k)}(x) = L_n^{(k+1)}(x) - L_{n-1}^{(k+1)}(x). \tag{20}$$

The DERIVATIVE is given by

$$\frac{d}{dx} L_n^{(k)}(x) = -L_{n-1}^{(k+1)}(x)$$

$$= x^{-1}[nL_n^{(k)}(x) - (n+k)L_{n-1}^{(k)}(x). \tag{21}$$

An interesting identity is

$$\sum_{n=0}^{\infty} \frac{L_n^{(k)}(x)}{\Gamma(n+k+1)} w^n = e^w (xw)^{-k/2} J_k(2\sqrt{xw}), \tag{22}$$

where $\Gamma(z)$ is the GAMMA FUNCTION and $J_k(z)$ is the BESSEL FUNCTION OF THE FIRST KIND (Szego 1975, p. 102). An integral representation is

$$e^{-x} x^{k/2} L_n^{(k)}(x) = \frac{1}{n!} \int_0^\infty e^{-t} t^{n+k/2} J_k\left(2\sqrt{tx}\right) dt \tag{23}$$

for $n = 0, 1, \ldots$and $k > -1$. The DISCRIMINANT is

$$D_n^{(k)} = \prod_{v=1}^{n} v^{v-2n+2}(v+k)^{v-1} \tag{24}$$

(Szego 1975, p. 143). The KERNEL POLYNOMIAL is

$$K_n^{(k)}(x, y) = \frac{n+1}{\Gamma(k+1)} \times \binom{n+k}{n}^{-1} \times \frac{L_n^{(k)}(x)L_{n+1}^{(k)}(y) - L_{n+1}^{(k)}(x)L_n(k)(y)}{x-y}, \quad (25)$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT (Szego 1975, p. 101).

The first few associated Laguerre polynomials are

$$L_0^k(x) = 1$$
$$L_1^k(x) = -x + k + 1$$
$$L_2^k(x) = \tfrac{1}{2}[x^2 - 2(k+2)x + (k+1)(k+2)]$$
$$L_3^k(x) = \tfrac{1}{6}[-x^3 + 3(k+3)x^2 - 3(k+2)(k+3)x + (k+1)(k+2)(k+3)].$$

Laguerre's Method

A ROOT-finding algorithm which converges to a COMPLEX ROOT from any starting position.

$$P_n(x) = (x-x_1)(x-x_2)\cdots(x-x_n) \quad (1)$$

$$\ln|P_n(x)| = \ln|x-x_1| + \ln|x-x_2| + \ldots + \ln|x-x_n| \quad (2)$$

$$P_n'(x) = (x-x_2)\cdots(x-x_n) + (x-x_1)\cdots(x-x_n) + \ldots = P_n(x)\left(\frac{1}{x-x_1} + \ldots + \frac{1}{x-x_n}\right) \quad (3)$$

$$\frac{d\ln|P_n(x)|}{dx} = \frac{1}{x-x_1} + \frac{1}{x-x_2} + \ldots + \frac{1}{x-x_n} = \frac{P_n'(x)}{P_n(x)} \equiv G(x) \quad (4)$$

$$-\frac{d^2\ln|P_n(x)|}{dx^2} = \frac{1}{(x-x_1)^2} + \frac{1}{(x-x_2)^2} + \ldots + \frac{1}{(x-x_n)^2} = \left[\frac{P_n'(x)}{P_n(x)}\right]^2 - \frac{P_n''(x)}{P_n(x)} \equiv H(x). \quad (5)$$

Now let $a \equiv x - x_1$ and $b \equiv x - x_1$. Then

$$G \equiv \frac{1}{a} + \frac{n-1}{b} \quad (6)$$

$$H \equiv \frac{1}{a^2} + \frac{n-1}{b^2}, \quad (7)$$

so

$$a = \frac{n}{\max\left[G \pm \sqrt{(n-1)(nH - G^2)}\right]}. \quad (8)$$

Setting $n = 2$ gives HALLEY'S IRRATIONAL FORMULA.

STAR OF LAKSHMI

L-Algebraic Number

An L-algebraic number is a number $\theta\in(0,\ 1)$ which satisfies

$$\sum_{k=0}^{n} c_k L(\theta^k)=0, \tag{1}$$

where $L(x)$ is the ROGERS L-FUNCTION and c_k are integers not all equal to 0 (Gordon and Mcintosh 1997). Loxton (1991, p. 289) gives a slew of similar identities having rational coefficients

$$\sum_{k=0}^{n} \frac{e_k}{k}\,L(\theta^k)=0 \tag{2}$$

instead of integers.

The only known L-algebraic numbers of order 1 are

$$L(0)=0 \tag{3}$$

$$L(1-\rho)=\tfrac{2}{5} \tag{4}$$

$$L\left(\tfrac{1}{2}\right)=\tfrac{1}{2} \tag{5}$$

$$L(\rho)=\tfrac{3}{5} \tag{6}$$

$$L(1)=1 \tag{7}$$

(Loxton 1991, pp. 287 and 289; Bytsko 1999), where $\rho=(\sqrt{5}-1)/2.$

The only known rational L-algebraic numbers are $1/2$ and $1/3$:

$$L\left(\tfrac{1}{64}\right)-2L\left(\tfrac{1}{8}\right)-6L\left(\tfrac{1}{4}\right)+2L(1)=0 \tag{8}$$

$$L\left(\tfrac{1}{9}\right)-6L\left(\tfrac{1}{3}\right)+2L(1)=0 \tag{9}$$

(Lewin 1982, pp. 317–18; Gordon and McIntosh 1997).

There are a number of known quadratic L-algebraic numbers. Watson (1937) found

$$L(\alpha)-L(\alpha^2)=\tfrac{1}{42}\pi^2 \tag{10}$$

$$2L(\beta)+L(\beta^2)=\tfrac{5}{21}\pi^2 \tag{11}$$

$$2L(\gamma)+L(\gamma^2)=\tfrac{4}{21}\pi^2, \tag{12}$$

where α, $-\beta$, and $-1/\gamma$ are the roots of

$$x^3+2x^2-1=0, \tag{13}$$

so that

$$\alpha=\tfrac{1}{2}\sec\left(\tfrac{2}{7}\pi\right) \tag{14}$$

$$\beta=\tfrac{1}{2}\sec\left(\tfrac{1}{7}\pi\right) \tag{15}$$

$$\gamma=2\cos\left(\tfrac{3}{7}\pi\right) \tag{16}$$

(Loxton 1991, pp. 287–88).

Higher order algebraic identities include

$$5L(\delta^3)-5L(\delta)+L(1)=0, \quad (17)$$

$$L(\delta^{12})-2L(\delta^6)-6L(\delta^4)+4L(\delta^3)+3L(\delta^2)+4L(\delta) -4L(1)=0 \quad (18)$$

$$3L(\kappa^3)-9L(\kappa^2)-9K(\kappa)+7L(1)=0 \quad (19)$$

$$3L(\lambda^6)-6L(\lambda^3)-27L(\lambda^2)+18L(\lambda)2L(1)=0 \quad (20)$$

$$3L(\mu^6)-6L(\mu^3)-27L(\mu^2)+18L(\mu)-2L(1)=0 \quad (21)$$

$$2L(a^3)-2L(a^2)-11L(a)+3L(1)=0 \quad (22)$$

$$2L(b^6)-4L(b^3)-15L(b^2)+22L(b)-6L(1)=0 \quad (23)$$

$$2L(c^6)-4L(c^3)-15L(c^2)+22L(c)-4L(1)=0,$$

where

$$\delta=\tfrac{1}{2}\left(\sqrt{3+2\sqrt{5}}-1\right) \quad (24)$$

$$\kappa=\tfrac{1}{2}\sec\left(\tfrac{1}{9}\pi\right) \quad (25)$$

$$\lambda=\tfrac{1}{2}\sec\left(\tfrac{2}{9}\pi\right) \quad (26)$$

$$\mu=2\cos\left(\tfrac{4}{9}\pi\right) \quad (27)$$

$$a=2\sqrt{3}\cos\left(\frac{5\pi}{18}\right)-2 \quad (28)$$

$$b=2\sqrt{3}\cos\left(\frac{11\pi}{18}\right)+2 \quad (29)$$

$$c=2\sqrt{3}\cos\left(\frac{7\pi}{18}\right)-1 \quad (30)$$

(Gordon and McIntosh 1997).

Lal's Constant

Let $P(N)$ denote the number of PRIMES OF THE FORM n^2+1 for $1\leq n\leq N$, then

$$P(N)\sim 0.68641\ \text{li}(N), \quad (1)$$

where $\text{li}(N)$ is the LOGARITHMIC INTEGRAL (Shanks 1960, pp. 321–32). Let $Q(N)$ denote the number of PRIMES OF THE FORM n^4+1 for $1\leq n\leq N$, then

$$Q(N)\sim \tfrac{1}{4}s_1\ \text{li}(N)=0.66974\ \text{li}(N) \quad (2)$$

(Shanks 1961, 1962). Let $R(N)$ denote the number of pairs of PRIMES $(n-1)^2+1$ and $(n+1)^2+1$ for $n\leq N-1$, then

$$R(N)\sim 0.487621\ \text{li}_2(N), \quad (3)$$

where

$$\text{li}_2(N)\equiv\int_2^N \frac{dn}{(\ln n)^2} \quad (4)$$

(Shanks 1960, pp. 201–03). Finally, let $S(N)$ denote the number of pairs of PRIMES $(n-1)^4+1$ and $(n+1)^4+1$ for $n\leq N-1$, then

$$S(N)\sim\lambda\ \text{li}_2(N) \quad (5)$$

(Lal 1967), where λ is called Lal's constant. Shanks (1967) showed that $\lambda\approx 0.79220$.

Lambda Elliptic Function

ELLIPTIC LAMBDA FUNCTION

Lambda Function

The lambda function defined by Jahnke and Emden (1945) is

$$\Lambda_\nu(z) \equiv \Gamma(\nu+1) \frac{J_\nu(z)}{\left(\frac{1}{2}z\right)^\nu} \tag{1}$$

where $J_n(z)$ is a BESSEL FUNCTION OF THE FIRST KIND and $\Gamma(x)$ is the GAMMA FUNCTION. $\Lambda_0(z) = J_0(z)$, and taking $\nu = 1$ gives the special case

$$\Lambda_1(z) \equiv \frac{J_1(z)}{\frac{1}{2}z} = 2\,\mathrm{jinc}(z), \tag{2}$$

where $\mathrm{jinc}(z)$ is the JINC FUNCTION.
A two-variable lambda function is defined as

$$\lambda(x,\ y) \equiv \int_0^y \frac{\Gamma(t+1)\,dt}{x^t}, \tag{3}$$

where $\Gamma(z)$ is the GAMMA FUNCTION (McLachlan *et al.* 1950, p. 9; Prudnikov *et al.* 1990, p. 798; Gradshteyn and Ryzhik 2000, p. 1109).

The MANGOLDT FUNCTION is sometimes called the lambda function.

Lambda Group

MODULAR GROUP LAMBDA

Lambda Modular Function

ELLIPTIC LAMBDA FUNCTION

Lambert Azimuthal Equal-Area Projection

A special case of a CYLINDRICAL EQUAL-AREA PROJECTION with standard parallel of $\phi_s = 0^\circ$.

$$x = k' \cos\phi \sin(\lambda - \lambda_0) \tag{1}$$

$$y = k'[\cos\phi_1 \sin\phi - \sin\phi_1 \cos\phi \cos(\lambda - \lambda_0)], \tag{2}$$

where

$$k' = \sqrt{\frac{2}{1 + \sin\phi_1 \sin\phi + \cos\phi_1 \cos\phi \cos(\lambda - \lambda_0)}}. \tag{3}$$

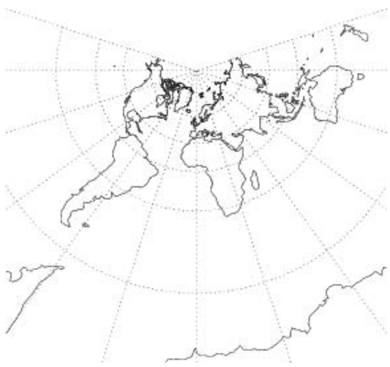
The inverse FORMULAS are

$$\phi = \sin^{-1}\left(\cos c \sin\phi_1 + \frac{y \sin c \cos\phi_1}{\rho}\right) \tag{4}$$

$$\lambda = \lambda_0 + \tan^{-1}\left(\frac{x \sin c}{\rho \cos\phi_1 \cos c - y \sin\phi_1 \sin c}\right), \tag{5}$$

where

$$\rho = \sqrt{x^2 + y^2} \tag{6}$$



$$c = 2\sin^{-1}\left(\tfrac{1}{2}\rho\right). \tag{7}$$

Lambert Conformal Conic Projection

Let λ be the longitude, λ_0 the reference longitude, ϕ the latitude, ϕ_0 the reference latitude, and ϕ_1 and ϕ_2 the standard parallels. Then the transformation of SPHERICAL COORDINATES to the plane via the Lambert conformal conic projection is given by

$$x = \rho \sin[n(\lambda - \lambda_0)] \quad (1)$$

$$y = \rho_0 - \rho \cos[n(\lambda - \lambda_0)], \quad (2)$$

where

$$\rho = F \cot^n\left(\tfrac{1}{4}\pi + \tfrac{1}{2}\phi\right) \quad (3)$$

$$\rho_0 = F \cot^n\left(\tfrac{1}{4}\pi + \tfrac{1}{2}\phi_0\right) \quad (4)$$

$$F = \frac{\cos\phi_1 \tan^n\left(\tfrac{1}{4}\pi + \tfrac{1}{2}\phi_1\right)}{n} \quad (5)$$

$$n = \frac{\ln(\cos\phi_1 \sec\phi_2)}{\ln\left[\tan\left(\tfrac{1}{4}\pi + \tfrac{1}{2}\phi_2\right)\cot\left(\tfrac{1}{4}\pi + \tfrac{1}{2}\phi_1\right)\right]}. \quad (6)$$

The inverse formulas are

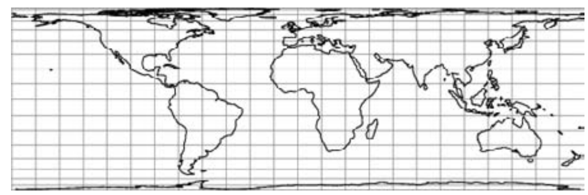
$$\phi = 2\tan^{-1}\left[\left(\frac{F}{\rho_0}\right)^{1/n}\right] - \tfrac{1}{2}\pi \quad (7)$$

$$\lambda = \lambda_0 + \frac{\theta}{n}, \quad (8)$$

where

$$\rho = \operatorname{sgn}(n)\sqrt{x^2 + (\rho_0 - y)^2} \quad (9)$$

$$\theta = \tan^{-1}\left(\frac{x}{\rho_0 - y}\right), \quad (10)$$



with F, ρ_0, and n as defined above.

A CYLINDRICAL EQUAL-AREA PROJECTION with standard parallel $\phi_s = 0°$.

See also CYLINDRICAL EQUAL-AREA PROJECTION

Lambert Series

A series OF THE FORM

$$F(x) \equiv \sum_{n=1}^{\infty} a_n \frac{x_n}{1 - x_n} \quad (1)$$

for $|x| < 1$. Then

$$F(x) = \sum_{n=1}^{\infty} a_n \sum_{m=1}^{\infty} x^{mn} = \sum_{N=1}^{\infty} b_N x^N, \quad (2)$$

where

$$b_N \equiv \sum_{n|N} a_n. \quad (3)$$

Some beautiful series of this type include

$$\sum_{n=1}^{\infty} \frac{\mu(n)x^n}{1 - x^n} = x \quad (4)$$

$$\sum_{n=1}^{\infty} \frac{\phi(n)x^n}{1 - x^n} = \frac{x}{(1 - x)^2} \quad (5)$$

$$\sum_{n=1}^{\infty} \frac{x^n}{1 - x^n} = \sum_{n=1}^{\infty} d(n)x^n \quad (6)$$

$$\sum_{n=1}^{\infty} \frac{n^k x^n}{1 - x^n} = \sum_{n=1}^{\infty} \sigma_k(n)x^n \quad (7)$$

$$\sum_{n=1}^{\infty} \frac{4(-1)^{n+1}x^n}{1 - x^n} = \sum_{n=1}^{\infty} r(n)x^n \quad (8)$$

$$\sum_{n=1}^{\infty} \frac{\lambda(n)x^n}{1 - x^n} = \sum_{n=1}^{\infty} x^{n^2}, \quad (9)$$

where $\mu(n)$ is the MÖBIUS FUNCTION, $\phi(n)$ is the TOTIENT FUNCTION, $d(n) = \sigma_0(n)$ is the number of divisors of n, $\sigma_k(n)$ is the DIVISOR FUNCTION, $r(n)$ is

the number of representations of n in the form $n = A^2 + B^2$ where A and B are rational integers (Hardy and Wright 1979), and $\lambda(n)$ is the LAMBDA FUNCTION.

See also DIVISOR FUNCTION, LAMBDA FUNCTION, MÖBIUS FUNCTION, MÖBIUS TRANSFORM, TOTIENT FUNCTION

Lambert's Transcendental Equation

An equation proposed by Lambert (1758) and studied by Euler in 1779 (Euler 1921).

$$x^\alpha - x^\beta = (\alpha - \beta)vx^{\alpha+\beta}.$$

When $\alpha \to \beta$, the equation becomes

$$\ln x = vx^\beta,$$

which has the solution

$$x = \exp\left[-\frac{W(-\beta v)}{\beta}\right],$$

where $W(x)$ is LAMBERT'S W-FUNCTION.

See also LAMBERT'S W-FUNCTION

Lambert's W-Function

The inverse of the function

$$f(W) = We^W, \tag{1}$$

also called the omega function. The plots above show the function along the REAL AXIS (left figure) and its RIEMANN SURFACE (right figure). The principal value of the Lambert W-function is implemented in *Mathematica* as `ProductLog[z]`. Different branches of the function are available as `ProductLog[k, z]`, where k is any integer and $k = 0$ corresponds to the principal value.

Lambert's W-function can be used to analytically express the value of the POWER TOWER $h(x) = x \uparrow\uparrow \infty = x^{x^{\cdot^{\cdot}}}$, where x^{x^x} is an abbreviation for $x^{(x^x)}$, as

$$h(x) = -\frac{W(-\ln x)}{\ln x}. \tag{2}$$

$W(1)$ is called the OMEGA CONSTANT and can be considered a sort of "GOLDEN RATIO" of exponentials since

$$\exp[-W(1)] = W(1), \tag{3}$$

giving

$$\ln\left[\frac{1}{W(1)}\right] = W(1). \tag{4}$$

Lambert's W-Function has the series expansion

$$W(x) = \sum_{n=1}^{\infty} \frac{(-1)^{n-1} n^{n-2}}{(n-1)!}\, x^n = x - x^2 + \tfrac{3}{2}x^3 - \tfrac{8}{3}x^4 + \tfrac{125}{24}x^5 - \tfrac{54}{5}x^6 + \tfrac{16807}{720}x^7 + \ldots \tag{5}$$

The LAGRANGE INVERSION THEOREM gives the equivalent series expansion

$$W_0(z) = \sum_{n=1}^{\infty} \frac{(-n)^{n-1}}{n!}\, z^n, \tag{6}$$

where $n!$ is a FACTORIAL. However, this series oscil-

lates between ever larger POSITIVE and NEGATIVE values for REAL $z \gtrsim 0.4$, and so cannot be used for practical numerical computation. An asymptotic FORMULA which yields reasonably accurate results for $z \gtrsim 3$ is

$$W(z) = \operatorname{Ln} z - \ln \operatorname{Ln} z + \sum_{k=0}^{\infty} \sum_{m=0}^{\infty} c_{km} (\ln \operatorname{Ln} z)^{m+1} \times (\operatorname{Ln} z)^{-k-m-1}$$

$$= L_1 - L_2 + \frac{L_2}{L_1} + \frac{L_2(-2+L_2)}{2L_1^2} + \frac{L_2(6-9L_2+2L_2^2)}{6L_1^3} + \frac{L_2(-12+36L_2-22L_2^2+3L_2^3)}{12L_1^4} + \frac{L_2(60-300L_2+350L_2^2-125L_2^3+12L_2^4)}{60L_1^5} + \mathcal{O}\left[\left(\frac{L_2}{L_1}\right)^6\right], \quad (7)$$

where

$$L_1 = \operatorname{Ln} z \quad (8)$$

$$L_2 = \ln \operatorname{Ln} z \quad (9)$$

(Corless *et al.* 1996), correcting a typographical error in de Bruijn (1961). Another expansion due to Gosper is the DOUBLE SUM

$$W(x) = a + \sum_{n=0}^{\infty} \left\{ \sum_{k=0}^{n} \frac{S_1(n,\ k)}{\left[\ln\left(\frac{x}{a}\right) - a\right]^{k-1} (n-k+1)!} \right\} \times \left[1 - \frac{\ln\left(\frac{x}{a}\right)}{a}\right]^n, \quad (10)$$

where S_1 is a *nonnegative* STIRLING NUMBER OF THE FIRST KIND and a is a first approximation which can be used to select between branches. Lambert's W-function is two-valued for $-1/e \leq x < 0$. For $W(x) \geq -1$, the function is denoted $W_0(x)$ or simply $W(x)$, and this is called the principal branch. For $W(x) \leq -1$, the function is denoted $W_{-1}(x)$. The DERIVATIVE of W is

$$W'(x) = \frac{1}{[1+W(x)]\exp[W(x)]} = \frac{W(x)}{x[1+W(x)]} \quad (11)$$

for $x \neq 0$. For the principal branch when $z > 0$,

$$\ln W(z) = \ln z - W(z) \quad (12)$$

Lamé Curve

There are two curves commonly known as the Lamé curve: the ELLIPSE EVOLUTE and the SUPERELLIPSE.

See also ELLIPSE EVOLUTE, SUPERELLIPSE

Lamé Function

ELLIPSOIDAL HARMONIC

Lamé's Differential Equation

The ORDINARY DIFFERENTIAL EQUATION

$$(x^2-b^2)(x^2-c^2)\frac{d^2z}{dx^2} + x(x^2-b^2+x^2-c^2)\frac{dz}{dx} - [m(m+1)x^2-(b^2+c^2)p]z = 0. \quad (1)$$

(Byerly 1959, p. 255). The solution is denoted $E_m^p(x)$ and is known as a LAMÉ FUNCTION or an ELLIPSOIDAL HARMONIC. Whittaker and Watson (1990, pp. 554–55) give the alternative forms

$$4\Delta_\lambda \frac{d}{d\lambda}\left[\Delta\lambda \frac{d\Lambda}{d\lambda}\right] = [n(n+1)\lambda + C]\Lambda \quad (2)$$

$$\frac{d^2\Lambda}{d\lambda^2}+\left[\frac{\frac{1}{2}}{a^2+\lambda}+\frac{\frac{1}{2}}{b^2+\lambda}+\frac{\frac{1}{2}}{c^2}\right]\frac{d\Lambda}{d\lambda} = \frac{[n(n+1)\lambda+C]\Lambda}{4\Delta_\lambda} \tag{3}$$

$$\frac{d^2\Lambda}{du^2}=\left[n(n+1)\wp(u)+C-\tfrac{1}{3}n(n+1)(a^2+b^2+c^2)\right]\Lambda \tag{4}$$

$$\frac{d^2\Lambda}{dz^2}=n(n+1)k^2\,\mathrm{sn}^2(z,\ k)+A\Lambda \tag{5}$$

(Whittaker and Watson 1990, pp. 554–55; Ward 1997; Zwillinger 1997, p. 124). Here, $\wp$ is a WEIERSTRASS ELLIPTIC FUNCTION, $\mathrm{sn}(z,\ k)$ is a JACOBI ELLIPTIC FUNCTION, and

$$\Lambda(\theta)\equiv\prod_{q=1}^{m}(\theta-\theta_q) \tag{6}$$

$$\Delta_\lambda\equiv\sqrt{(a^2+\lambda)(b^2+\lambda)(c^2+\lambda)} \tag{7}$$

$$A\equiv\frac{C-\frac{1}{3}n(n+1)(a^2+b^2+c^2)+e_3n(n+1)}{e_1-e_3}. \tag{8}$$

Two other equations named after Lamé are given by

$$y''+\tfrac{1}{2}\left[\frac{1}{x-a_1}+\frac{1}{x-a_2}+\frac{1}{x-a_3}\right]y' +\tfrac{1}{4}\left[\frac{A_0+A_1x}{(x-a_1)(x-a_2)(x-a_3)}\right]y=0 \tag{9}$$

and

$$y''+\tfrac{1}{2}\left[\frac{1}{x}+\frac{1}{x-a_2}+\frac{1}{x-a_3}\right]y' +\tfrac{1}{4}\left[\frac{(a_2^2+a_3^2)q-p(p+1)x+\kappa x^2}{x(x-a_2)(x-a_3)}\right]y=0 \tag{10}$$

(Moon and Spencer 1961, p. 157; Zwillinger 1997, p. 124).

Lamé's Differential Equation Types

Whittaker and Watson (1990, pp. 539–40) write Lamé's differential equation for ELLIPSOIDAL HARMONICS of the four types as

$$4\delta(\theta)\frac{d}{d\theta}\left[f(\theta)\frac{d\lambda(\theta)}{d\theta}\right]=[2m(2m+1)\theta+c]\lambda(\theta) \tag{1}$$

$$4\delta(\theta)\frac{d}{d\theta}\left[f(\theta)\frac{d\lambda(\theta)}{d\theta}\right]=[(2m+1)(2m+2)\theta+c]\lambda(\theta) \tag{2}$$

$$4\delta(\theta)\frac{d}{d\theta}\left[f(\theta)\frac{d\lambda(\theta)}{d\theta}\right]=[(2m+2)(2m+3)\theta+c]\lambda(\theta) \tag{3}$$

$$4\delta(\theta)\frac{d}{d\theta}\left[f(\theta)\frac{d\lambda(\theta)}{d\theta}\right]=[(2m+3)(2m+4)\theta+c]\lambda(\theta), \tag{4}$$

where

$$\delta(\theta)\equiv\sqrt{(a^2+\theta)(b^2+\theta)(c^2+\theta)} \tag{5}$$

$$\lambda(\theta)\equiv\prod_{q=1}^{m}(\theta-\theta_q). \tag{6}$$

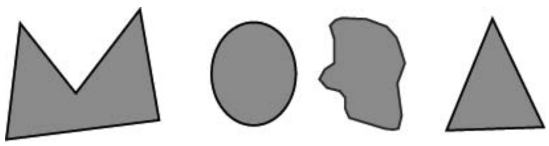
Lamé's Theorem



If a is the smallest INTEGER for which there is a smaller INTEGER b such that a and b generate a EUCLIDEAN ALGORITHM remainder sequence with n steps, then a is the FIBONACCI NUMBER F_{n+2}. Furthermore, the number of steps in the EUCLIDEAN ALGORITHM never exceeds 5 times the number of digits in the smaller number.

Lamp Paradox

THOMPSON LAMP PARADOX

Lam's Problem

Given a 111×111 BINARY MATRIX, fill 11 spaces in each row in such a way that all columns also have 11 spaces filled. Furthermore, each pair of rows must have exactly one filled space in the same column. This problem is equivalent to finding a PROJECTIVE PLANE of order 10. Using a computer program, Lam *et al.* (1989) showed that no such arrangement exists.

Lam's problem is equivalent to finding nine orthogonal LATIN SQUARES of order 10.

Lanczos Approximation

An approximation for the GAMMA FUNCTION $\Gamma(z+1)$ with $z > 0$ is given by

$$\Gamma(z+1) = \sqrt{2\pi} \times \left(z + \sigma + \tfrac{1}{2}\right)^{z+1/2} e^{-(z+\sigma+1/2)} \sum_{k=0}^{\infty} g_k H_k(z), \quad (1)$$

where σ is an arbitrary constant such that $\Re[z + \sigma + 1/2] > 0$,

$$g_k = \frac{e^\sigma \epsilon_k (-1)^k}{\sqrt{2\pi}} \sum_{r=0}^{k} (-1)^r \binom{k}{r} (k)_r \left(\frac{e}{r + \sigma + \frac{1}{2}}\right)^{r+1/2} \quad (2)$$

where $(k)_r$ is a POCHHAMMER SYMBOL and

$$\epsilon_k = \begin{cases} 1 & \text{for } k = 0 \\ 2 & \text{otherwise,} \end{cases} \quad (3)$$

and

$$H_k(z) = \frac{1}{(z+1)_k (z+1)_{-k}} \quad (4)$$

$$= \frac{(-1)^k (-z)^k}{(z+1)_k}, \quad (5)$$

with $H_0(z) = 1$ (Lanczos 1964; Luke 1969, p. 30). g_k satisfies

$$\sum_{k=0}^{\infty} g_k = 1, \quad (6)$$

and if z is a POSITIVE INTEGER, then g_k satisfies the identity

$$\sum_{k=0}^{n} \frac{(-1)^k(-n)_k}{(n+1)_k} g_k = \frac{e^{n+\sigma+1/2} n!}{\sqrt{2\pi}(n+\sigma+1/2)^{n+1/2}} \tag{7}$$

(Luke 1969, p. 30).

A similar result is given by

$$\ln[\Gamma(z)] = \left(z - \tfrac{1}{2}\right)\ln z - z + \tfrac{1}{2}\ln(2\pi) + \tfrac{1}{2}\left[\frac{c_1}{z+1} + \frac{c_2}{2(z+1)(z+2)} + \ldots\right] \tag{8}$$

where

$$c_n = \int_0^1 (x)_n (2x-1)\, dx, \tag{9}$$

with $(x)_n$ a POCHHAMMER SYMBOL. The first few values of c_n are

$$c_1 = \tfrac{1}{6}$$

$$c_2 = \tfrac{1}{3}$$

$$c_3 = \tfrac{59}{60}$$

$$c_4 = \tfrac{58}{15}$$

$$c_5 = \tfrac{533}{28}$$

(Sloane's A054379 and A054380; Whittaker and Watson 1990, p. 253). Note that Whittaker and Watson incorrectly give c_4 as 227/60.

Yet another related result gives

$$\ln[\Gamma(z)] = \left(z - \tfrac{1}{2}\right)\ln z - z + \tfrac{1}{2}\ln(2\pi) + \tfrac{1}{2}\left[\frac{1}{2\cdot 3}\sum_{r=1}^{\infty}\frac{1}{(z+r)^2} + \frac{2}{3\cdot 4}\sum_{r=1}^{\infty}\frac{1}{(z+r)^3} + \frac{3}{4\cdot 5}\sum_{r=1}^{\infty}\frac{1}{(z+r)^4} + \ldots\right] \tag{10}$$

(Whittaker wand Watson 1990, p. 261).

Landau Constant

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Let F be the set of COMPLEX analytic functions f defined on an open region containing the closure of the unit disk $D = \{z : |z| < 1\}$ satisfying $f(0) = 0$ and $df/dz(0) = 1$. For each f in F, let (f) be the SUPREMUM of all numbers r such that $f(D)$ contains a disk of radius r. Then

$$L \equiv \inf\{l(f) : f \in F\}.$$

This constant is called the Landau constant, or the BLOCH-LANDAU CONSTANT. Robinson (1938, unpublished) and Rademacher (1943) derived the bounds

$$\tfrac{1}{2} < L \leq \frac{\Gamma\left(\frac{1}{3}\right)\Gamma\left(\frac{5}{6}\right)}{\Gamma\left(\frac{1}{6}\right)} = 0.5432588\ldots,$$

where $\Gamma(z)$ is the GAMMA FUNCTION, and conjectured that the second inequality is actually an equality,

$$L = \frac{\Gamma\left(\frac{1}{3}\right)\Gamma\left(\frac{5}{6}\right)}{\Gamma\left(\frac{1}{6}\right)} = 0.5432588\ldots.$$

See also BLOCH CONSTANT

References

Landau-Kolmogorov Constants

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Let $\|f\|$ be the SUPREMUM of $|f(x)|$, a real-valued function f defined on $(0, \infty)$. If f is twice differentiable and both f and f'' are bounded, Landau (1913) showed that

$$||f'|| \leq 2||f||^{1/2}||f''||^{1/2}, \tag{1}$$

where the constant 2 is the best possible. Schoenberg (1973) extended the result to the nth derivative of f defined on $(0, \infty)$ if both f and $f^{(n)}$ are bounded,

$$||f^{(k)}|| \leq C(n, k)||f||^{1-k/n}||f(n)||^{k/n}. \tag{2}$$

An explicit FORMULA for $C(n, k)$ is not known, but particular cases are

$$C(3, 1) = \left(\frac{243}{8}\right)^{1/3} \tag{3}$$

$$C(3, 2) = 24^{1/3} \tag{4}$$

$$C(4, 1) = 4.288\ldots \tag{5}$$

$$C(4, 2) = 5.750\ldots \tag{6}$$

$$C(4, 3) = 3.708\ldots. \tag{7}$$

Let $||f||$ be the SUPREMUM of $|f(x)|$, a real-valued function f defined on $(-\infty, \infty)$. If f is twice differentiable and both f and f'' are bounded, Hadamard (1914) showed that

$$||f'|| \leq \sqrt{2}||f||^{1/2}||f''||^{1/2}, \tag{8}$$

where the constant $\sqrt{2}$ is the best possible. Kolmogorov (1962) determined the best constants $C(n, k)$ for

$$||f^{(k)}|| \leq C(n, k)||f||^{1-k/n}||f^{(n)}||^{k/n} \tag{9}$$

in terms of the FAVARD CONSTANTS

$$a_n = \frac{4}{\pi}\sum_{j=0}^{\infty}\left[\frac{(-1)^j}{2j+1}\right]^{n+1} \tag{10}$$

by

$$C(n, k) = a_{n-k}a_n^{-1+k/n}. \tag{11}$$

Special cases derived by Shilov (1937) are

$$C(3, 1) = \left(\frac{9}{8}\right)^{1/3} \tag{12}$$

$$C(3, 2) = 3^{1/3} \tag{13}$$

$$C(4, 1) = \left(\frac{512}{375}\right)^{1/4} \tag{14}$$

$$C(4, 2) = \sqrt{\frac{6}{5}} \tag{15}$$

$$C(4, 3) = \left(\frac{24}{5}\right)^{1/4} \tag{16}$$

$$C(5, 1) = \left(\frac{1953125}{1572864}\right)^{1/5} \tag{17}$$

$$C(5, 2) = \left(\frac{125}{72}\right)^{1/5}. \tag{18}$$

For a real-valued function f defined on $(-\infty, \infty)$, define

$$||f||\sqrt{\int_{-\infty}^{\infty}[f(x)]^2\,dx}. \tag{19}$$

If f is n differentiable and both f and $f^{(n)}$ are bounded, Hardy *et al.* (1934) showed that

$$||f^{(k)}|| \leq ||f||^{1-k/n}||f^{(n)}||^{k/n}, \tag{20}$$

where the constant 1 is the best possible for all n and $0 < k < n$.

For a real-valued function f defined on $(0, \infty)$, define

$$||f|| = \sqrt{\int_0^{\infty}[f(x)]^2\,dx}. \tag{21}$$

If f is twice differentiable and both f and f'' are bounded, Hardy *et al.* (1934) showed that

$$||f'|| \leq \sqrt{2}||f||^{1/2}||f^{(n)}||^{1/2}, \tag{22}$$

where the constant $\sqrt{2}$ is the best possible. This inequality was extended by Ljubic (1964) and Kupcov (1975) to

$$||f^{(k)}|| \leq C(n, k)||f||^{1-k/n}||f^{(n)}||^{k/n} \tag{23}$$

where $C(n, k)$ are given in terms of zeros of POLYNOMIALS. Special cases are

$$C(3, 1) = C(3, 2) = 3^{1/2}[2(2^{1/2}-1)]^{-1/3} = 1.84420\ldots \tag{24}$$

$$C(4, 1) = C(4, 3) = \sqrt{\frac{3^{1/4}+3^{-3/4}}{a}} = 2.27432\ldots \tag{25}$$

$$C(4, 2) = \sqrt{\frac{2}{b}} = 2.97963\ldots \tag{26}$$

$$C(4, 3) = \left(\frac{24}{5}\right)^{1/4} \tag{27}$$

$$C(5, 1) = C(5, 4) = 2.70247\ldots \tag{28}$$

$$C(5, 2) = C(5, 3) = 4.37800\ldots, \tag{29}$$

where a is the least POSITIVE ROOT of

$$x^8 - 6x^4 - 8x^2 + 1 = 0 \tag{30}$$

and b is the least POSITIVE ROOT of

$$x^4 - 2x^2 - 4x + 1 = 0 \tag{31}$$

(Franco *et al.* 1985, Neta 1980). The constants $C(n,\ 1)$ are given by

$$C(n,\ 1) = \sqrt{\frac{(n-1)^{1/n} + (n+1)^{-1+1/n}}{c}}, \tag{32}$$

where c is the least POSITIVE ROOT of

$$\int_0^c \int_0^\infty \frac{dx\, dy}{(x^{2n} - yx^2 + 1)\sqrt{y}} = \frac{\pi^2}{2n}. \tag{33}$$

An explicit FORMULA of this type is not known for $k > 1$.

The cases $p = 1,\ 2,\ \infty$ are the only ones for which the best constants have exact expressions (Kwong and Zettl 1992, Franco *et al.* 1983).

Landau-Ramanujan Constant

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Let $S(x)$ denote the number of POSITIVE INTEGERS not exceeding x which can be expressed as a sum of two squares, then

$$\lim_{x\to\infty} \frac{\sqrt{\ln x}}{x} S(x) = K, \tag{1}$$

as proved by Landau (1908). Ramanujan independently stated the theorem in the slightly different form that the number of numbers between A and x which are either squares of sums of two squares is

$$S(x) = K \int_A^x \frac{dt}{\sqrt{\ln t}} + \theta(x), \tag{2}$$

where $K \approx 0.764$ and $\theta(x)$ is very small compared with the previous integral (Hardy 1999, p. 8; Moree and Cazaran 1999). However, the convergence to the constant K is very slow.

The exact value for

$$K = 0.764223653\ldots \tag{3}$$

(sometimes denoted λ) is given by

$$K = \frac{1}{\sqrt{2}} \prod_{\substack{p \text{ prime} \\ \equiv 3 \pmod 4}} \left(1 - \frac{1}{p^2}\right)^{-1/2} \tag{4}$$

(Landau 1908; Le Lionnais 1983, p. 31; Berndt 1994; Hardy 1999; Moree and Cazaran 1999). An equivalent formula is given by

$$K = \frac{\pi}{4} \prod_{\substack{p \text{ prime} \\ \equiv 1 \pmod 4}} \left(1 - \frac{1}{p^2}\right)^{-1/2}. \tag{5}$$

Flajolet and Vardi (1996) give a beautiful FORMULA with fast convergence

$$K = \frac{1}{\sqrt{2}} \prod_{n=1}^{\infty} \left[\left(1 - \frac{1}{2^{2^n}}\right) \frac{\zeta(2^n)}{\beta(2^n)}\right]^{1/(2^n+1)}, \tag{6}$$

where

$$\beta(s) \equiv \frac{1}{4^s}\left[\zeta\left(s, \tfrac{1}{4}\right) - \varsigma\left(s, \tfrac{3}{4}\right)\right] \tag{7}$$

is the DIRICHLET BETA FUNCTION, and $\zeta(z, a)$ is the HURWITZ ZETA FUNCTION. Landau proved the even stronger fact

$$\lim_{x\to\infty} \frac{(\ln x)^{3/2}}{Kx}\left[S(x) \frac{Kx}{\sqrt{\ln x}}\right] = C, \tag{8}$$

where

$$C \equiv \frac{1}{2}\left[1 - \ln\left(\frac{\pi e^{\gamma}}{L}\right)\right] - \frac{1}{4}\frac{d}{ds}\left[\ln\left(\prod_{\substack{p \text{ prime} \\ p=4k+3}} \frac{1}{p^{-2s}}\right)\right]_{s=1}$$

$$= 0.581948659\ldots. \tag{9}$$

Here,

$$L = 5.2441151086\ldots \tag{10}$$

is the ARC LENGTH of a LEMNISCATE with $a = 1$ (the LEMNISCATE CONSTANT to within a factor of 2 or 4), and γ is the EULER-MASCHERONI CONSTANT.

Landau's method of proof can be extended to show that

$$B(x) \sim K \frac{x}{\sqrt{\ln x}} \tag{11}$$

has an ASYMPTOTIC SERIES

$$B(x) = K \frac{x}{\sqrt{\ln x}} \times \left[1 + \frac{C_1}{\ln x} + \frac{C_2}{(\ln x)^2} + \ldots + \frac{C_n}{(\ln x)^n} + \mathcal{O}\left(\frac{1}{(\ln x)^{n+1}}\right)\right], \tag{12}$$

where n can be arbitrarily large and the C_j are constants (Moree and Cazaran 1999).

Landau's Problems

The four "unattackable" problems mentioned by Landau in the 1912 Fifth Congress of Mathematicians in Cambridge. The four were

1. The GOLDBACH CONJECTURE,
2. TWIN PRIME CONJECTURE,
3. The conjecture that there exists a PRIME p such that $n^2 < p < (n+1)^2$ for every n (Hardy and Wright 1979, p. 415; Ribenboim 1996, pp. 397–98), and
4. The conjecture that there are infinitely many PRIMES p OF THE FORM $p = n^2 + 1$ (Hardy and Wright 1979, p. 19; Ribenboim 1996, pp. 206–08).

The first few PRIMES p which are OF THE FORM $p = n^2 + 1$ are given by 2, 5, 17, 37, 101, 197, 257, 401, ... (Sloane's A002496). These correspond to $n = 1$, 2, 4, 6, 10, 14, 16, 20, ... (Sloane's A005574; Hardy and Wright 1979, p. 19).

Although it is not know if there always exists a PRIME p such that $n^2 < p < (n+1)^2$, Chen (1975) has shown that a number P which is either a PRIME or SEMIPRIME does always satisfy this inequality. Moreover, there is always a prime between $n - n^{\theta}$ and n where $\theta = 23/42$ (Iwaniec and Pintz 1984; Hardy and Wright 1979, p. 415). The smallest PRIMES between n^2 and $(n+1)^2$ for $n = 1$, 2, ..., are 2, 5, 11, 17, 29, 37, 53, 67, 83, ... (Sloane's A007491).

Lane-Emden Differential Equation

A second-order ORDINARY DIFFERENTIAL EQUATION arising in the study of stellar interiors, also called the polytropic differential equations. It is given by

$$\frac{1}{\xi^2}\frac{d}{d\xi}\left(\xi^2\frac{d\theta}{d\xi}\right) + \theta^n = 0 \tag{1}$$

$$\frac{1}{\xi^2}\left(2\xi\frac{d\theta}{d\xi} + \xi^2\frac{d^2\theta}{d\xi^2}\right) + \theta^n = \frac{d^2\theta}{d\xi^2} + \frac{2}{\xi}\frac{d\theta}{d\xi} + \theta^n = 0 \tag{2}$$

(Zwillinger 1997, pp. 124 and 126). It has the BOUNDARY CONDITIONS

$$\theta(0) = 1 \tag{3}$$

$$\left[\frac{d\theta}{d\xi}\right]_{\xi=0} = 0. \tag{4}$$

Solutions $\theta(\xi)$ for $n=0$, 1, 2, 3, and 4 are shown above. The cases $n=0$, 1, and 5 can be solved analytically (Chandrasekhar 1967, p. 91); the others must be obtained numerically.

For $n=0$ ($(\gamma=\infty)$), the LANE-EMDEN DIFFERENTIAL EQUATION is

$$\frac{1}{\xi^2}\frac{d}{d\xi}\left(\xi^2\frac{d\theta}{d\xi}\right)+1=0 \tag{5}$$

(Chandrasekhar 1967, pp. 91–2). Directly solving gives

$$\frac{d}{d\xi}\left(\xi^2\frac{d\theta}{d\xi}\right)+1=-\xi^2 \tag{6}$$

$$\int d\left(\xi^2\frac{d\theta}{d\xi^2}\right)=-\int \xi^2\, d\xi \tag{7}$$

$$\xi^2\frac{d\theta}{d\xi}=c_1-\tfrac{1}{3}\xi^3 \tag{8}$$

$$\frac{d\theta}{d\xi}=\frac{c_1-\frac{1}{3}\xi^3}{\xi^2} \tag{9}$$

$$\theta(\xi)=\int d\theta=\int\frac{c_1-\frac{1}{3}\xi^3}{\xi^2}\,d\xi \tag{10}$$

$$\theta(\xi)=\theta_0-c_1\xi^{-1}-\tfrac{1}{6}\xi^2. \tag{11}$$

The BOUNDARY CONDITION $\theta(0)=1$ then gives $\theta_0=1$ and $c_1=0$, so

$$\theta_1(\xi)=1-\tfrac{1}{6}\xi^2, \tag{12}$$

and $\theta_1(\xi)$ is PARABOLIC.

For $n=1$ ($\gamma=2$), the differential equation becomes

$$\frac{1}{\xi^2}\frac{d}{d\xi}\left(\xi^2\frac{d\theta}{d\xi}\right)+\theta=0 \tag{13}$$

$$\frac{d}{d\xi}\left(\xi^2\frac{d\theta}{d\xi}\right)+\theta\xi^2=0, \tag{14}$$

which is the SPHERICAL BESSEL DIFFERENTIAL EQUATION

$$\frac{d}{dr}\left(r^2\frac{dR}{dr}\right)+[k^2r^2-n(n+1)]R=0 \tag{15}$$

with $k=1$ and $n=0$, so the solution is

$$\theta(\xi)=Aj_0(\xi)+Bn_0(\xi). \tag{16}$$

Applying the BOUNDARY CONDITION $\theta(0)=1$ gives

$$\theta_2(\xi)=j_0(\xi)=\frac{\sin\xi}{\xi}, \tag{17}$$

where $j_0(x)$ is a SPHERICAL BESSEL FUNCTION OF THE FIRST KIND (Chandrasekhar 1967, pp. 92).

For $n=5$, make Emden's transformation

$$\theta=Ax^{\omega}z \tag{18}$$

$$\omega=\frac{2}{n-1}, \tag{19}$$

which reduces the Lane-Emden equation to

$$\frac{d^2z}{dt^2}+(2\omega-1)\frac{dz}{dt}+\omega(\omega-1)z+A^{n-1}z^n=0 \tag{20}$$

(Chandrasekhar 1967, p. 90). After further manipulation (not reproduced here), the equation becomes

$$\frac{d^2z}{dt^2}=\tfrac{1}{4}z(1-z^4) \tag{21}$$

and then, finally,

$$\theta_5(\xi)=\left(1+\tfrac{1}{3}\xi^2\right)^{-1/2}. \tag{22}$$

Langford's Problem

Arrange copies of the n digits 1, ..., n such that there is one digit between the 1s, two digits between the 2s, etc. For example, the unique (modulo reversal) $n=3$ solution is 231213, and the unique (again modulo reversal) $n=4$ solution is 23421314. Solutions to Langford's problem exist only if $n\equiv 0,\ 3 \pmod 4$, so the next solutions occur for $n=7$. There are 26 of these, as exhibited by Lloyd (1971). In lexicographically smallest order (i.e., small digits come first), the first few Langford sequences are 231213, 23421314, 14156742352637, 14167345236275, 15146735423627, ... (Sloane's A050998).

The number of solutions for $n=3,\ 4,\ 5,\ \dots$ (modulo reversal of the digits) are 1, 1, 0, 0, 26, 150, 0, 0, 17792, 108144, ... (Sloane's A014552). No formula is known for the number of solutions of a given order $n\not\equiv 0,\ 3 \pmod 4$..

Langlands Conjectures

LANGLANDS PROGRAM

Langlands Program

A grand unified theory of mathematics which includes the search for a generalization of ARTIN RECIPROCITY (known as LANGLANDS RECIPROCITY) to non-Abelian Galois extensions of NUMBER FIELDS. In a January 1967 letter to André Weil, Langlands proposed that the mathematics of algebra (Galois representations) and analysis (AUTOMORPHIC FORMS) are intimately related, and that congruences over FINITE FIELDS are related to infinite-dimensional representation theory. In particular, Langlands conjectured that the transformations behind general reciprocity laws could be represented by means of MATRICES (Mackenzie 2000).

In 1998, three mathematicians proved Langlands' conjectures for LOCAL FIELDS, and in a November 1999 lecture at the Institute for Advanced Study at Princeton University, L. Lafforgue presented a proof of the conjectures for FUNCTION FIELDS. This leaves only the case of NUMBER FIELDS as unresolved (Mackenzie 2000).

Langlands was a co-recipient of the 1996 Wolf Prize for the web of conjectures underlying this program.

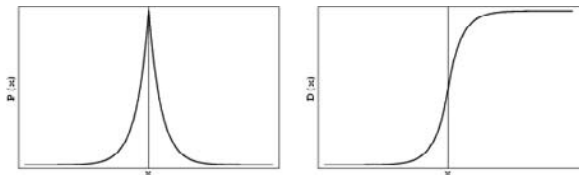
Laplace-Beltrami Operator

A self-adjoint elliptic differential operator defined somewhat technically as



$$\Delta = d\delta + \delta d,$$

where d is the EXTERIOR DERIVATIVE and d and δ are adjoint to each other with respect to the INNER PRODUCT.

References

Iyanaga, S. and Kawada, Y. (Eds.). *Encyclopedic Dictionary of Mathematics.* Cambridge, MA: MIT Press, p. 628, 1980.

Laplace Distribution

Also called the DOUBLE EXPONENTIAL DISTRIBUTION. It is the distribution of differences between two independent variates with identical EXPONENTIAL DISTRIBUTIONS (Abramowitz and Stegun 1972, p. 930).

$$P(x) = \frac{1}{2b}\, e^{-|x-\mu|/b} \qquad (1)$$

$$D(x) = \tfrac{1}{2}[1 + \operatorname{sgn}(x-\mu)(1 - e^{-|x-\mu|/b})]. \qquad (2)$$

The MOMENTS about the MEAN μ_n are related to the MOMENTS about 0 by

$$\mu_n = \sum_{j=0}^{n} \binom{n}{j} (-1)^{n-j} \mu'_j \mu^{n-j}, \qquad (3)$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT, so

$$\mu_n = \sum_{j=0}^{n} \sum_{k=0}^{\lfloor j/2 \rfloor} (-1)^{n-j} \binom{n}{j} \binom{j}{2k} b^{2k} \mu^{n-2k} \Gamma(2k+1)$$

$$= \begin{cases} n! b^n & \text{for } n \text{ even} \\ 0 & \text{for } n \text{ odd,} \end{cases} \tag{4}$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION and $\Gamma(2k+1)$ is the GAMMA FUNCTION. The MOMENTS can also be computed using the CHARACTERISTIC FUNCTION,

$$\phi(t) \equiv \int_{-\infty}^{\infty} e^{itx} P(x) dx = \frac{1}{2b} \int_{-\infty}^{\infty} e^{itx} e^{-|x-\mu|/b} \, dx. \tag{5}$$

Using the FOURIER TRANSFORM OF THE EXPONENTIAL FUNCTION

$$\mathscr{F}[e^{-2\pi k_0 |x|}] = \frac{1}{\pi} \frac{k_0}{k^2 + k_0^2} \tag{6}$$

gives

$$\phi(t) = \frac{e^{i\mu t}}{2b} \frac{\frac{2}{b}}{t^2 + \left(\frac{1}{b}\right)^2} = \frac{e^{i\mu t}}{1 + b^2 t^2} \tag{7}$$

(Abramowitz and Stegun 1972, p. 930). The MOMENTS are therefore

$$\mu_n = (-i)^n \phi(0) = (-i)^n \left[\frac{d^n \phi}{dt^n} \right]_{t=0}. \tag{8}$$

The MEAN, VARIANCE, SKEWNESS, and KURTOSIS are

$$\mu = \mu \tag{9}$$

$$\sigma^2 = 2b^2 \tag{10}$$

$$\gamma_1 = 0 \tag{11}$$

$$\gamma_2 = 3. \tag{12}$$

Laplace-Everett Formula

EVERETT'S FORMULA

Laplace Limit

The value $e = 0.6627434193\ldots$ (Sloane's A033259) for which Laplace's formula for solving KEPLER'S EQUATION begins diverging. The constant is defined as the value e at which the function

$$f(x) = \frac{x \exp(\sqrt{1+x^2})}{1 + \sqrt{1+x^2}}$$

equals $f(\lambda) = 1$. The CONTINUED FRACTION of e is given by [0, 1, 1, 1, 27, 1, 1, 1, 8, 2, 154, ...] (Sloane's A033260). The positions of the first occurrences of n in the CONTINUED FRACTION of e are 2, 10, 35, 13, 15, 32, 101, 9, ... (Sloane's A033261). The incrementally largest terms in the CONTINUED FRACTION are 1, 27, 154, 1601, 2135, ... (Sloane's A033262), which occur at positions 2, 5, 11, 19, 1801, ... (Sloane's A033263).

Laplace's Equation

The scalar form of Laplace's equation is the PARTIAL DIFFERENTIAL EQUATION

$$\nabla^2 \psi = 0. \tag{1}$$

Note that the operator ∇^2 is commonly written as Δ by mathematicians (Krantz 1999, p. 16). Laplace's equation is a special case of the HELMHOLTZ DIFFERENTIAL EQUATION

$$\nabla^2 \psi + k^2 \psi = 0 \tag{2}$$

with $k = 0$, or POISSON'S EQUATION

$$\nabla^2 \psi = -4\pi\rho \tag{3}$$

with $\rho = 0$. The vector Laplace's equation is given by

$$\nabla^2 \mathbf{F} = 0. \tag{4}$$

A function ψ which satisfies Laplace's equation is said to be harmonic. A solution to Laplace's equation has the property that the average value over a spherical surface is equal to the value at the center of the sphere (Gauss's harmonic function theorem). Solutions have no local maxima or minima. Because Laplace's equation is linear, the superposition of any two solutions is also a solution.

A solution to Laplace's equation is uniquely determined if (1) the value of the function is specified on all boundaries (Dirichlet boundary conditions) or (2) the normal derivative of the function is specified on all boundaries (Neumann boundary conditions).

Coordinate System	Variables	Solution Functions
Cartesian	$X(x)Y(y)Z(z)$	exponential functions, circular functions, hyperbolic functions
circular cylindrical	$R(r)\Theta(\theta)Z(z)$	Bessel functions, exponential functions, circular functions
conical		ellipsoidal harmonics, power
ellipsoidal	$\Lambda(\lambda)M(\mu)N(\nu)$	ellipsoidal harmonics
elliptic cylindrical	$U(u)V(v)Z(z)$	Mathieu function, circular functions
oblate spheroidal	$\Lambda(\lambda)M(\mu)N(\nu)$	Legendre polynomial, circular functions
parabolic		Bessel functions, circular functions
parabolic cylindrical		parabolic cylinder functions, Bessel functions, circular functions
paraboloidal	$U(u)V(v)\Theta(\theta)$	circular functions
prolate spheroidal	$\Lambda(\lambda)M(\mu)N(\nu)$	Legendre polynomial, circular functions
spherical	$R(r)\Theta(\theta)\Phi(\phi)$	Legendre polynomial, power, circular functions

Laplace's equation can be solved by separation of variables in all 11 coordinate systems that the Helmholtz differential equation can. The form these solutions take is summarized in the table above. In addition to these 11 coordinate systems, separation can be achieved in two additional coordinate systems by introducing a multiplicative factor. In these coordinate systems, the separated form is

$$\psi = \frac{X_1(u_1)X_2(u_2)X_3(u_3)}{R(u_1,\ u_2,\ u_3)}, \tag{5}$$

and setting

$$\frac{h_1h_2h_3}{h_i^2} = g_i(u_{i+1},\ u_{i+2})f_i(u_i)R^2, \tag{6}$$

where h_i are scale factors, gives the Laplace's equation

$$\sum_{i=1}^{3} \frac{1}{h_i^2 X_i}\left[\frac{1}{f_i}\frac{d}{du_i}\left(f_i\frac{dX_i}{du_i}\right)\right] = \sum_{i=1}^{3} \frac{1}{h_i^2 R}\left[\frac{1}{f_i}\frac{\partial}{\partial u_i}\left(f_i\frac{\partial R}{\partial u_i}\right)\right]. \tag{7}$$

If the right side is equal to $-k_1^2/F(u_1,\ u_2,\ u_3)$, where k_1 is a constant and F is any function, and if

$$h_1h_2h_3 = Sf_1f_2f_3R^2F, \tag{8}$$

where S is the Stäckel determinant, then the equation can be solved using the methods of the Helmholtz differential equation. The two systems where this is the case are bispherical and toroidal, bringing the total number of separable systems for Laplace's equation to 13 (Morse and Feshbach 1953, pp. 665–66).

In 2-D bipolar coordinates, Laplace's equation is separable, although the Helmholtz differential equation is not.

Zwillinger (1997, p. 128) calls

$$(a_0x+b_0)y^{(n)} + (a_1x+b_1)y^{(n-1)} + \ldots + (a_nx+b_n)y = 0 \tag{9}$$

the Laplace equations.

Laplace's Equation—Bipolar Coordinates

In 2-D BIPOLAR COORDINATES, LAPLACE'S EQUATION is

$$\frac{(\cosh v - \cos u)^2}{a^2}\left(\frac{\partial F^2}{\partial u^2}+\frac{\partial F^2}{\partial v^2}\right)=0, \tag{1}$$

which simplifies to

$$\frac{\partial F^2}{\partial u^2}+\frac{\partial F^2}{\partial v^2}=0, \tag{2}$$

so LAPLACE'S EQUATION is separable, although the HELMHOLTZ DIFFERENTIAL EQUATION is not.

See also BIPOLAR COORDINATES, LAPLACE'S EQUATION

Laplace's Equation—Bispherical Coordinates

In BISPHERICAL COORDINATES, LAPLACE'S EQUATION becomes

$$\nabla^2 f = \frac{\sin u}{(\cosh v - \cos u)^3}\left[\frac{\partial}{\partial u}\left(\frac{\sin u}{\cosh v - \cos u}\frac{\partial f}{\partial u}\right) + \frac{\partial}{\partial v}\left(\frac{\sin u}{\cosh v - \cos u}\frac{\partial f}{\partial v}\right) + \frac{\partial}{\partial \phi} \times \left(\frac{\csc u}{\cosh v - \cos u}\frac{\partial f}{\partial \phi}\right)\right]. \tag{1}$$

Attempt SEPARATION OF VARIABLES by plugging in the trial solution

$$f(u,\ v,\ \phi)=\sqrt{\cosh v - \cos u}\,U(u)V(v)\Psi(\psi), \tag{2}$$

then divide the result by $\csc^2 u(\cosh v - \cos u)^{5/2}$ $U(u)V(v)\Phi(\phi)$ to obtain

$$-\tfrac{1}{4}\sinh^2 u + \cos u \sin u\frac{U'(u)}{U(u)} + \sin^2 u\frac{U''(u)}{U(u)} + \sin^2 u\frac{V''(v)}{V(v)} + \frac{\Phi''(\phi)}{\Phi(\phi)} = 0. \tag{3}$$

The function $\Phi(\phi)$ then separates with

$$\frac{\Phi''(\phi)}{\Phi(\phi)} = -m^2, \tag{4}$$

giving solution

$$\Psi(\psi) = \frac{\sin}{\cos}(m\phi) = \sum_{k=1}^{\infty}[A_k \sin(m\psi) + B_k \cos(m\psi)]. \tag{5}$$

Plugging $\Psi(\psi)$ back in and dividing by $\sin^2 u$ gives

$$\cot u\frac{U'(u)}{U(u)} + \frac{U''(u)}{U(u)} - \frac{m^2}{\sin^2 u} - \frac{1}{4} + \frac{V''(v)}{V(v)} = 0. \tag{6}$$

The function $V(v)$ then separates with

$$\frac{V''(v)}{V(v)} = -n^2, \tag{7}$$

giving solution

$$V(v) = \frac{\sin}{\cos}(nv) = \sum_{k=1}^{\infty}[C_k \sin(nv) + D_k \cos(nv)]. \tag{8}$$

Plugging $V(v)$ back in and multiplying by $V(v)$ gives

$$U''(u) + \cot u\,U'(u) - \left[\frac{m^2}{\sin^2 u} + \left(n^2 + \tfrac{1}{4}\right)\right]U(u) = 0, \tag{9}$$

so LAPLACE'S EQUATION is partially separable in BISPHERICAL COORDINATES. However, the HELMHOLTZ DIFFERENTIAL EQUATION cannot be separated in this manner.

Laplace's Equation—Spherical Coordinates

Laplace's Equation–Spherical

HELMHOLTZ DIFFERENTIAL EQUATION–SPHERICAL COORDINATES

Laplace's Equation—Toroidal Coordinates

In TOROIDAL COORDINATES, LAPLACE'S EQUATION becomes

$$\nabla^2 f = \frac{\sinh u}{(\cosh u - \cos v)^3}\left[\frac{\partial}{\partial u}\left(\frac{\sinh u}{\cosh u - \cos v}\frac{\partial f}{\partial u}\right) + \frac{\partial}{\partial v}\left(\frac{\sinh u}{\cosh u - \cos v}\frac{\partial f}{\partial v}\right) + \frac{\partial}{\partial \phi} \times \left(\frac{\operatorname{csch} u}{\cosh u - \cos v}\frac{\partial f}{\partial \phi}\right)\right] \quad (1)$$

Attempt SEPARATION OF VARIABLES by plugging in the trial solution

$$f(u, v, \phi) = \sqrt{\cosh u - \cos u}\, U(u)V(v)\Psi(\psi), \quad (2)$$

then divide the result by $\operatorname{csch}^2 u(\cosh u - \cos v)^{5/2}$ $U(u)V(v)\Phi(\phi)$ to obtain

$$\tfrac{1}{4}\sinh^2 u + \cosh u \sinh u \frac{U'(u)}{U(u)} + \sin^2 u \frac{U''(u)}{U(u)} + \sinh^2 u \frac{V''(v)}{V(v)} + \frac{\Phi''(\phi)}{\Phi(\phi)} = 0. \quad (3)$$

The function $\Phi(\phi)$ then separates with

$$\frac{\Phi''(\phi)}{\Phi(\phi)} = -m^2, \quad (4)$$

giving solution

$$\Psi(\psi) = \frac{\sin}{\cos}(m\phi) = \sum_{k=1}^{\infty}[A_k \sin(m\psi) + B_k \cos(m\psi)]. \quad (5)$$

Plugging $\Psi(\psi)$ back in and dividing by $\sinh^2 u$ gives

$$\coth u \frac{U'(u)}{U(u)} + \frac{U''(u)}{U(u)} - \frac{m^2}{\sinh^2 u} + \frac{1}{4} + \frac{V''(v)}{V(v)} = 0. \quad (6)$$

The function $V(v)$ then separates with

$$\frac{V''(v)}{V(v)} = -n^2, \quad (7)$$

giving solution

$$V(v) = \frac{\sin}{\cos}(nv) = \sum_{k=1}^{\infty}[C_k \sin(nv) + D_k \cos(nv)]. \quad (8)$$

Plugging $V(v)$ back in and multiplying by $V(v)$ gives

$$U''(u) + \coth u U'(u) - \left[\frac{m^2}{\sinh^2 u} + \left(n^2 - \tfrac{1}{4}\right)\right]U(u) = 0, \quad (9)$$

which can also be written

$$\frac{1}{\sinh u}\frac{d}{du}\left(\sinh u \frac{dU}{du}\right) - \left[\frac{m^2}{\sinh^2 u} + \left(n^2 - \tfrac{1}{4}\right)\right]U = 0 \quad (10)$$

(Arfken 1970, pp. 114–15). LAPLACE'S EQUATION is partially separable, although the HELMHOLTZ DIFFERENTIAL EQUATION is not.

See also LAPLACE'S EQUATION, LAPLACIAN, TOROIDAL COORDINATES

Laplace Series

A function $f(\theta, \phi)$ expressed as a double sum of SPHERICAL HARMONICS is called a Laplace series. Taking f as a COMPLEX FUNCTION,

$$f(\theta, \phi) = \sum_{l=0}^{\infty}\sum_{m=-1}^{l} a_{lm} Y_l^m(\theta, \phi). \quad (1)$$

Now multiply both sides by $\bar{Y}_{l'}^{m'} \sin\theta$ and integrate over $d\theta$ and $d\phi$.

$$\int_0^{2\pi}\int_0^{\pi} f(\theta, \phi)\bar{Y}_{l'}^{m'} \sin\theta \, d\theta \, d\phi = \sum_{l=0}^{\infty}\sum_{m=-1}^{l} a_{lm}\int_0^{2\pi}\int_0^{\pi}\bar{Y}_{l'}^{m'}(\theta, \phi)Y_l^m(\theta, \phi)\sin\theta \, d\theta \, d\phi. \quad (2)$$

Now use the ORTHOGONALITY of the SPHERICAL HARMONICS

$$\int_0^{2\pi}\int_0^{\pi} Y_l^m(\theta, \phi)\bar{Y}_{l'}^{m'} \sin\theta \, d\theta \, d\phi = \delta_{mm'}\delta_{ll'}, \quad (3)$$

so (2) becomes

$$\int_0^{2\pi}\int_0^{\pi} f(\theta,\ \phi)\bar{Y}_{l'}^{m'} \sin\theta\, d\theta\, d\phi = \sum_{l=0}^{\infty}\sum_{m=-1}^{l} a_{lm}\delta_{mm'}\delta_{ll'} = a_{lm}, \tag{4}$$

where δ_{mn} is the KRONECKER DELTA.

For a REAL series, consider

$$f(\theta,\ \phi) = \sum_{l=0}^{\infty}\sum_{m=-1}^{l} [C_l^m \cos(m\phi) + S_l^m \sin(m\phi)]P_l^m(\cos\theta). \tag{5}$$

Proceed as before, using the orthogonality relationships

$$\int_0^{2\pi}\int_0^{\pi} P_l^m(\cos\theta)\cos(m\phi)P_{l'}^{m'}(\cos\theta)\cos(m'\phi) \times \sin(\theta)\, d\theta\, d\phi = -\frac{2\pi(l+m)!}{(2l+1)(l-m)!}\delta_{mm'}\delta_{ll'} \tag{6}$$

$$\int_0^{2\pi}\int_0^{\pi} P_l^m(\cos\theta)\sin(m\phi)P_{l'}^{m'}(\cos\theta)\sin(m'\phi) \times \sin\theta\, d\theta\, d\phi = -\frac{2\pi(l+m)!}{(2l+1)(l-m)!}\delta_{mm'}\delta_{ll'}. \tag{7}$$

So C_l^m and S_l^m are given by

$$C_l^m = -\frac{(2l+1)(l-m)!}{2\pi(l+m)!}\int_0^{2\pi}\int_0^{\pi} f(\theta,\ \phi) \times P_l^m \cos\theta\cos(m\phi)\sin\theta\, d\theta\, d\phi \tag{8}$$

$$S_l^m = -\frac{(2l+1)(l-m)!}{2\pi(l+m)!}\int_0^{2\pi}\int_0^{\pi} f(\theta,\ \phi) \times P_l^m \cos\theta\sin(m\phi)\sin\theta\, d\theta\, d\phi. \tag{9}$$

Laplace's Integral

$$P_n(x) = \frac{1}{\pi}\int_0^{\pi} \frac{du}{\left(x+\sqrt{x^2-1}\cos u\right)^{n+1}}\, du = \frac{1}{\pi}\int_0^{\pi}\left(x+\sqrt{x^2-1}\cos u\right)^n du.$$

It can be evaluated in terms of the HYPERGEOMETRIC FUNCTION.

Laplace's Problem

BUFFON-LAPLACE NEEDLE PROBLEM

Laplace-Stieltjes Transform

An integral transform which is often written as an ordinary LAPLACE TRANSFORM involving the DELTA FUNCTION. The LAPLACE TRANSFORM and DIRICHLET SERIES are special cases of the Laplace-Stieltjes transform (Apostol 1997, p. 162).

See also DIRICHLET SERIES, LAPLACE TRANSFORM

Laplace Transform

The Laplace transform is an INTEGRAL TRANSFORM perhaps second only to the FOURIER TRANSFORM in its utility in solving physical problems. Due to its useful properties, the Laplace transform is particularly useful in solving linear ORDINARY DIFFERENTIAL EQUATIONS such as those arising in the analysis of electronic circuits.

The (one-sided) Laplace transform $\mathcal{L}$ (not to be confused with the LIE DERIVATIVE) is defined by

$$\mathcal{L}(s) = \mathcal{L}[f(t)] \equiv \int_0^{\infty} f(t)e^{-st}\, dt, \tag{1}$$

where $f(t)$ is defined for $t \geq 0$. The one-sided Laplace transform is implemented in *Mathematica* as `LaplaceTransform[`*expr*`, `*t*`, `*s*`]`.

A two-sided Laplace transform is sometimes also defined by

$$\mathcal{L}(s) = \mathcal{L}|f(t)| = \int_{-\infty}^{\infty} f(t)e^{-st}\, dt. \tag{2}$$

The Laplace transform existence theorem states that, if $f(t)$ is PIECEWISE CONTINUOUS function on every finite interval in $[0,\ \infty)$ satisfying

$$|f(t)| \leq Me^{at} \tag{3}$$

for all $t \in [0,\ \infty)$, then $\mathcal{L}[f(t)]$ exists for all $s > a$. The Laplace transform is also UNIQUE, in the sense that, given two functions $F_1(t)$ and $F_2(t)$ with the same transform so that

$$\mathcal{L}[F_1(t)] = \mathcal{L}[F_2(t)] \equiv f(s), \tag{4}$$

then LERCH'S THEOREM guarantees that the integral

$$\int_0^a N(t)\, dt = 0 \tag{5}$$

vanishes for all $a > 0$ for a NULL FUNCTION defined by

$$N(t) \equiv F_1(t) - F_2(t). \tag{6}$$

The Laplace transform is LINEAR since

$$\mathcal{L}[af(t) + bg(t)] = \int_0^{\infty} [af(t) + bg(t)]e^{-st}\, dt$$

$$= a \int_0^\infty f(t)e^{-st}\,dt + b \int_0^\infty g(t)e^{-st}\,dt$$

$$= a\mathscr{L}[f(t)] + b\mathscr{L}[g(t)]. \tag{7}$$

The inverse Laplace transform is given by the BROMWICH INTEGRAL (see also DUHAMEL'S CONVOLUTION PRINCIPLE). A table of several important Laplace transforms follows.

$f(t)$	$\mathscr{L}[f(t)]$	Range
1	$\frac{1}{s}$	$s > 0$
t	$\frac{1}{s^2}$	$s > 0$
t^n	$\frac{n!}{s^{n+1}}$	$n \in \mathbb{Z} > 0$
t^a	$\frac{\Gamma(a+1)}{s^{a+1}}$	$a > 0$
e^{at}	$\frac{1}{s-a}$	$s > a$
$\cos(\omega t)$	$\frac{s}{s^2+\omega^2}$	$s > 0$
$\sin(\omega t)$	$\frac{\omega}{s^2+\omega^2}${\it s} \hskip -1.80\ma-threl{{\tf="DM5"\char21}}\hskip -1.80 0\crcosh(ωt)	$\frac{s}{s^2-\omega^2}$
$s > \lvert a \rvert$		
$\sinh(\omega t)$	$\frac{\omega}{s^2-\omega^2}$	$s > \lvert a \rvert$
$e^{at}\sin(bt)$	$\frac{b}{(s-a)^2+b^2}$	$s > a$
$e^{at}\cos(bt)$	$\frac{s-a}{(s-a)^2+b^2}$	$s > a$
$\delta(t-c)$	e^{-cs}	$c > 0$
$H_c(t)$	$\frac{e^{-cs}}{s}$	$s > 0$
$J_0(t)$	$\frac{1}{\sqrt{s^2+1}}$	
$J_n(t)$	$\frac{{}_2F_1\left(\frac{1}{2}(n+1), \frac{1}{2}(n+2); n+1; -s^{-2}\right)}{2^n s^{n+1}}$	

In the above table, $J_0(t)$ is the zeroth order BESSEL FUNCTION OF THE FIRST KIND, $\delta(t)$ is the DELTA FUNCTION, and $H_c(t)$ is the HEAVISIDE STEP FUNCTION. The Laplace transform has many important properties.

The Laplace transform of a CONVOLUTION is given by

$$\mathscr{L}[f(t) * g(t)] = \mathscr{L}(f(t))\mathscr{L}(g(t)) \tag{8}$$

$$\mathscr{L}^{-1}[F(s)G(s)] = \mathscr{L}^{-1}(F(s)) * \mathscr{L}^{-1}(G(s)). \tag{9}$$

Now consider DIFFERENTIATION. Let $f(t)$ be continuously differentiable $n-1$ times in $[0, \infty)$. If $|f(t)| \leq Me^{at}$, then

$$\mathscr{L}[f^{(n)}(t)] = s^n \mathscr{L}(f(t)) - s^{n-1}f(0) - s^{n-2}f'(0) - \ldots - f^{(n-1)}(0). \tag{10}$$

This can be proved by INTEGRATION BY PARTS,

$$\mathscr{L}[f'(t)] = \lim_{a\to\infty} \int_0^a e^{-st} f'(t)\,dt$$

$$= \lim_{a\to\infty} \left\{ [e^{-st}f(t)]_0^a + s \int_0^a e^{-st} f(t)\,dt \right\}$$

$$= \lim_{a\to\infty} \left[[e^{-sa}f(a) - f(0) + s \int_0^a e^{-st} f(t)\,dt \right]$$

$$= s\mathscr{L}[f(t)] - f(0). \tag{11}$$

Continuing for higher order derivatives then gives

$$\mathscr{L}[f''(t)] = s^2 \mathscr{L}[f(t)] - sf(0) - f'(0). \tag{12}$$

This property can be used to transform differential equations into algebraic equations, a procedure known as the HEAVISIDE CALCULUS, which can then be inverse transformed to obtain the solution. For example, applying the Laplace transform to the equation

$$f''(t) + a_1 f'(t) + a_0 f(t) = 0 \tag{13}$$

gives

$$\{s^2 \mathscr{L}[f(t)] - sf(0) - f'(0)\} + a_1\{s\mathscr{L}[f(t)] - f(0)\} + a_0 \mathscr{L}[f(t)] = 0 \tag{14}$$

$$\mathscr{L}[f(t)](s^2 + a_1 s + a_0) - sf(0) - f'(0) - a_1 f(0) = 0, \tag{15}$$

which can be rearranged to

$$\mathscr{L}[f(t)] = \frac{sf(0) + [f'(0) + a_1 f(0)]}{s^2 + a_1 s + a_0}. \tag{16}$$

If this equation can be inverse Laplace transformed, then the original differential equation is solved.

Consider EXPONENTIATION. If $\mathscr{L}[f(t)] = F(s)$ for $s > \alpha$, then $\mathscr{L}(e^{at}f(t)) = F(s-a)$ for $s > a + \alpha$.

$$F(s-a) = \int_0^\infty f(t)e^{-(s-a)t}\,dt = \int_0^\infty [f(t)e^{at}]e^{-st}\,dt$$

$$= \mathscr{L}[e^{at}f(t)]. \tag{17}$$

Consider INTEGRATION. If $f(t)$ is PIECEWISE CONTINUOUS and $|f(t)| \leq Me^{at}$, then

$$\mathscr{L}\left[\int_0^t f(t)\,dt\right] = \frac{1}{s}\,\mathscr{L}[f(t)]. \tag{18}$$

The inverse transform is known as the BROMWICH INTEGRAL, or sometimes the FOURIER-MELLIN INTEGRAL.

See also BROMWICH INTEGRAL, FOURIER-MELLIN INTEGRAL, FOURIER TRANSFORM, INTEGRAL TRANSFORM, LAPLACE-STIELTJES TRANSFORM, OPERATIONAL MATHEMATICS

Laplacian

The Laplacian operator for a SCALAR function ϕ is defined by

$$\nabla^2\phi = \frac{1}{h_1\,h_2\,h_3}\left[\frac{\partial}{\partial u_1}\left(\frac{h_2 h_3}{h_1}\,\frac{\partial}{\partial u_1}\right) + \frac{\partial}{\partial u_2}\left(\frac{h_1 h_3}{h_2}\,\frac{\partial}{\partial u_2}\right) + \frac{\partial}{\partial u_3}\left(\frac{h_1 h_2}{h_3}\,\frac{\partial}{\partial u_3}\right)\right]\phi \tag{1}$$

in VECTOR notation, where the h_i are the SCALE FACTORS of the coordinate system. In TENSOR notation, the Laplacian is written

$$\nabla^2\phi = (g^{\lambda\kappa}\phi_{;\lambda})_{;\kappa} = g^{\lambda\kappa}\,\frac{\partial^2\phi}{\partial x^\lambda \partial x^\kappa} - \Gamma^\lambda\,\frac{\partial\phi}{\partial x^\lambda}$$

$$= \frac{1}{\sqrt{g}}\,\frac{\partial}{\partial x^j}\left(\sqrt{g}\,g^{ij}\,\frac{\partial\phi}{\partial x^i}\right), \tag{2}$$

where $g_{;\kappa}$ is a COVARIANT DERIVATIVE and

$$\Gamma^\lambda \equiv \tfrac{1}{2}\,g^{\mu\nu}g^{\lambda\kappa}\left(\frac{\partial g_{\kappa\mu}}{\partial x^\nu} + \frac{\partial g_{\kappa\nu}}{\partial x^\mu} - \frac{\partial g_{\mu\nu}}{\partial x^\kappa}\right). \tag{3}$$

Note that the operator ∇^2 is commonly written as Δ by mathematicians (Krantz 1999, p. 16).

The following table gives the form of the Laplacian in several common coordinate systems.

coordinate system	∇^2
CARTESIAN COORDINATES	$\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2}$
CYLINDRICAL COORDINATES	$\frac{1}{r}\frac{\partial}{\partial r}\left(r\,\frac{\partial f}{\partial r}\right) + \frac{1}{r^2}\frac{\partial^2 f}{\partial \theta^2} + \frac{\partial^2 f}{\partial z^2}$
PARABOLIC COORDINATES	$\frac{1}{uv(u^2+v^2)}\left[\frac{\partial}{\partial u}\left(uv\,\frac{\partial f}{\partial u}\right) + \frac{\partial}{\partial v}\left(uv\,\frac{\partial f}{\partial v}\right)\right]$
	$+\frac{1}{u^2v^2}\frac{\partial^2 f}{\partial \theta^2}$
PARABOLIC CYLINDRICAL COORDINATES	$\frac{1}{u^2+v^2}\left(\frac{\partial^2 f}{\partial u^2} + \frac{\partial^2 f}{\partial v^2}\right) + \frac{\partial^2 f}{\partial z^2}$
SPHERICAL COORDINATES	$\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\,\frac{\partial}{\partial r}\right) + \frac{1}{r^2\sin^2\phi}\frac{\partial^2}{\partial \theta^2}$
	$+\frac{1}{r^2\sin\phi}\frac{\partial}{\partial \phi}\left(\sin\phi\,\frac{\partial}{\partial \phi}\right)$

The finite difference form is

$$\nabla^2\psi(x,\,y,\,z) = \frac{1}{h^2}[\psi(x+h,\,y,\,z) + \psi(x-h,\,y,\,z)$$

$$+\psi(x,\,y+h,\,z) + \psi(x,\,y-h,\,z) + \psi(x,\,y,\,z+h)$$

$$+\psi(x,\,y,\,z-h) - 6\psi(x,\,y,\,z)]. \tag{4}$$

For a pure radial function $g(r)$,

$$\nabla^2 g(r) \equiv \nabla\cdot[\nabla g(r)]$$

$$= \nabla \cdot \left[\frac{\partial g(r)}{\partial r}\hat{\mathbf{r}} + \frac{1}{r}\frac{\partial g(r)}{\partial \theta}\hat{\boldsymbol{\theta}} + \frac{1}{r\sin\theta}\frac{\partial g(r)}{\partial \phi}\hat{\phi}\right]$$

$$= \nabla \cdot \left(\hat{\mathbf{r}}\frac{dg}{dr}\right). \tag{5}$$

Using the VECTOR DERIVATIVE identity

$$\nabla \cdot (f\mathbf{A}) = f(\nabla \cdot \mathbf{A}) + (\nabla f) \cdot (\mathbf{A}), \tag{6}$$

so

$$\nabla^2 g(r) \equiv \nabla \cdot [\nabla g(r)] = \frac{dg}{dr}\nabla \cdot \hat{\mathbf{r}} + \nabla\left(\frac{dg}{dr}\right) \cdot \hat{\mathbf{r}}$$

$$= \frac{2}{r}\frac{dg}{dr} + \frac{d^2 g}{dr^2}. \tag{7}$$

Therefore, for a radial power law,

$$\nabla^2 r^n = \frac{2}{r}nr^{n-1} + n(n-1)r^{n-2} = [2n + n(n-1)]r^{n-2}$$

$$= n(n+1)r^{n-2}. \tag{8}$$

A vector Laplacian can also be defined for a VECTOR $\mathbf{A}$ by

$$\nabla^2 \mathbf{A} = \nabla(\nabla \cdot \mathbf{A}) - \nabla \times (\nabla \times \mathbf{A}) \tag{9}$$

in vector notation. The notation ☆ is sometimes also used for a vector Laplacian (Moon and Spencer 1988, p. 3). In tensor notation, $\mathbf{A}$ is written A_μ, and the identity becomes

$$\nabla^2 A_\mu = A_{\mu;\lambda}^{;\lambda} = (g^{\lambda\kappa} A_{\mu;\lambda})_{;\kappa}$$

$$= g^{\lambda}{}_{\kappa;\kappa} A_{\mu;\lambda} + g^{\lambda\kappa} A_{\mu;\lambda\kappa}. \tag{10}$$

Similarly, a TENSOR Laplacian can be given by

$$\nabla^2 A_{\alpha\beta} = A_{\alpha\beta;\lambda}^{;\lambda}. \tag{11}$$

An identity satisfied by the Laplacian is

$$\nabla^2 |\mathbf{x}\mathsf{A}| = \frac{|\mathsf{A}|_2^2 - |(\mathbf{x}\mathsf{A})\mathsf{A}^{\mathrm{T}}|^2}{|\mathbf{x}\mathsf{A}|^3}, \tag{12}$$

where $|\mathsf{A}|_2$ is the HILBERT-SCHMIDT NORM, $\mathbf{x}$ is a row VECTOR, and A^{T} is the MATRIX TRANSPOSE of A.

To compute the LAPLACIAN of the inverse distance function $1/r$, where $r \equiv |\mathbf{r} - \mathbf{r}'|$, and integrate the LAPLACIAN over a volume,

$$\int_V \nabla^2 \left(\frac{1}{|\mathbf{r} - \mathbf{r}'|}\right) d^3\mathbf{r}. \tag{13}$$

This is equal to

$$\int_V \nabla^2 \frac{1}{r} d^3\mathbf{r} = \int_V \nabla \cdot \left(\nabla \frac{1}{r}\right) d^3\mathbf{r} = \int_S \left(\nabla \frac{1}{r}\right) \cdot d\mathbf{a}$$

$$= \int_S \frac{\partial}{\partial r}\left(\frac{1}{r}\right)\hat{\mathbf{r}} \cdot d\mathbf{a} = \int_S -\frac{1}{r^2}\hat{\mathbf{r}} \cdot d\mathbf{a}$$

$$= -4\pi \frac{R^2}{r^2}, \tag{14}$$

where the integration is over a small SPHERE of RADIUS R. Now, for $r > 0$ and $R \to 0$, the integral becomes 0. Similarly, for $r = R$ and $R \to 0$, the integral becomes -4π. Therefore,

$$\nabla^2 \left(\frac{1}{|\mathbf{r} - \mathbf{r}'|}\right) = -4\pi\delta^3(\mathbf{r} - \mathbf{r}'), \tag{15}$$

where $\delta(\mathbf{x})$ is the DELTA FUNCTION.

The tensor Laplacian is given by

$$\nabla \cdot (\nabla \psi) = \frac{1}{g^{1/2}}(g^{1/2} g^{ik} \psi_{,k})_{,i}, \tag{16}$$

where g_{ij} is the METRIC TENSOR, $g = \det(g_{ij})$, and $A_{,k}$ is the COMMA DERIVATIVE (Arfken 1985, p. 185).

DETERMINANT EXPANSION BY MINORS

Laplacian Expansion

DETERMINANT EXPANSION BY MINORS

Laplacian Matrix

The Laplacian matrix $L(G)$ of a graph G, where $G = (N, E)$ is an undirected, unweighted graph without self edges (i, i) or multiple edges from one node to another, is an $|N| \times |N|$ SYMMETRIC MATRIX with one row and column for each node. It is defined as follows,

$$L_{ij}(G) = \begin{cases} \text{degree of node } i & \text{if } i = j \\ -1 & \text{if } i \neq j \text{ and } \exists \text{ edge}(i, j) \\ 0 & \text{otherwise.} \end{cases}$$

A normalized version of the Laplacian matrix, denoted $\mathcal{L}$, is similar defined by

$$\mathscr{L}_{ij}(G) = \begin{cases} 1 & \text{if } i = j \text{ and } d_j \neq 0 \\ -\dfrac{1}{\sqrt{d_i d_j}} & \text{if } i \text{ and } j \text{ are adjacent} \\ 0 & \text{otherwise.} \end{cases}$$

Large Number

There are a wide variety of large numbers which crop up in mathematics. Some are contrived, but some actually arise in proofs. Often, it is possible to prove existence theorems by deriving some potentially huge upper limit which is frequently greatly reduced in subsequent versions (e.g., GRAHAM'S NUMBER, KOLMOGOROV-ARNOLD-MOSER THEOREM, MERTENS CONJECTURE, SKEWES NUMBER, WANG'S CONJECTURE).

Large decimal numbers beginning with 10^9 are named according to two mutually conflicting nomenclatures: the American system (in which the prefix stands for n in 10^{3+3n}) and the British system (in which the prefix stands for n in 10^{6n}). However, it should be noted that in more recent years, the "American" system is now widely used in England as well as in the United States. The following table gives the names assigned to various POWERS of 10 (Woolf 1982).

American	British	power of 10
MILLION	million	10^6
BILLION	milliard	10^9
TRILLION	billion	10^{12}
QUADRILLION		10^{15}
QUINTILLION	trillion	10^{18}

EIGENVECTOR

Latin Cross

An irregular DODECAHEDRON CROSS in the shape of a dagger †. The six faces of a CUBE can be cut along seven EDGES and unfolded into a Latin cross (i.e., the Latin cross is the NET of the CUBE). Similarly, eight hypersurfaces of a HYPERCUBE can be cut along 17 SQUARES and unfolded to form a 3-D Latin cross.

Another cross also called the Latin cross is illustrated above. It is a GREEK CROSS with flared ends, and is also known as the crux immissa or cross patée.

See also CROSS, DISSECTION, DODECAHEDRON, GREEK CROSS, MALTESE CROSS

Latin-Graeco Square

EULER SQUARE

Latin Rectangle

A $k \times n$ Latin rectangle is a $k \times n$ MATRIX with elements $a_{ij} \in \{1, 2, \ldots, n\}$ such that entries in each row and column are distinct. If $k = n$, the special case of a LATIN SQUARE results. A normalized Latin rectangle has first row $\{1, 2, \ldots, n\}$ and first column $\{1, 2, \ldots, k\}$. Let $L(k, n)$ be the number of normalized $k \times n$ Latin rectangles, then the total number of $k \times n$ Latin rectangles is

$$N(k, n) = \frac{n!(n-1)!L(k, n)}{(n-k)!}$$

(McKay and Rogoyski 1995), where $n!$ is a FACTORIAL. Kerewala (1941) found a RECURRENCE RELATION for $L(3, n)$, and Athreya, Pranesachar, and Singhi (1980) found a summation FORMULA for $L(4, n)$.

The asymptotic value of $L(o(n^{6/7}), n)$ was found by Godsil and McKay (1990). The numbers of $k \times n$ Latin rectangles are given in the following table from McKay and Rogoyski (1995). The entries $L(1, n)$ and $L(n, n)$ are omitted, since

$$L(1, n) = 1$$

$$L(n, n) = L(n-1, n),$$

but $L(1, 1)$ and $L(2, 1)$ are included for clarity. The values of $L(k, n)$ are given as a "wrap-around" series by Sloane's A001009.

Latin Square

An $n \times n$ Latin square is a LATIN RECTANGLE with $k = n$. Specifically, a Latin square consists of n sets of the numbers 1 to n arranged in such a way that no orthogonal (row or column) contains the same two numbers. The numbers of Latin squares of order $n = 1, 2, ...$ are 1, 2, 12, 576, 161280, ... (Sloane's A002860). For example, the two Latin squares of order two are given by

$$\begin{bmatrix} 1 & 2 \\ 2 & 1 \end{bmatrix}, \begin{bmatrix} 2 & 1 \\ 1 & 2 \end{bmatrix}, \tag{1}$$

the 12 Latin squares of order three are given by

$$\begin{bmatrix} 1 & 2 & 3 \\ 2 & 3 & 1 \\ 3 & 1 & 2 \end{bmatrix}, \begin{bmatrix} 1 & 2 & 3 \\ 3 & 1 & 2 \\ 2 & 3 & 1 \end{bmatrix}, \begin{bmatrix} 1 & 3 & 2 \\ 2 & 1 & 3 \\ 3 & 2 & 1 \end{bmatrix}, \begin{bmatrix} 1 & 3 & 2 \\ 3 & 2 & 1 \\ 2 & 1 & 3 \end{bmatrix},$$

$$\begin{bmatrix} 2 & 1 & 3 \\ 1 & 3 & 2 \\ 3 & 2 & 1 \end{bmatrix}, \begin{bmatrix} 2 & 1 & 3 \\ 3 & 2 & 1 \\ 1 & 3 & 2 \end{bmatrix}, \begin{bmatrix} 2 & 3 & 1 \\ 1 & 2 & 3 \\ 3 & 1 & 2 \end{bmatrix}, \begin{bmatrix} 2 & 3 & 1 \\ 3 & 1 & 2 \\ 1 & 2 & 3 \end{bmatrix},$$

$$\begin{bmatrix} 3 & 2 & 1 \\ 1 & 3 & 2 \\ 2 & 1 & 3 \end{bmatrix}, \begin{bmatrix} 3 & 2 & 1 \\ 2 & 1 & 3 \\ 1 & 3 & 2 \end{bmatrix}, \begin{bmatrix} 3 & 1 & 2 \\ 1 & 2 & 3 \\ 2 & 3 & 1 \end{bmatrix}, \begin{bmatrix} 3 & 1 & 2 \\ 2 & 3 & 1 \\ 1 & 2 & 3 \end{bmatrix}, \tag{2}$$

and two of the whopping 576 Latin squares of order 4 are given by

$$\begin{bmatrix} 1 & 2 & 3 & 4 \\ 2 & 1 & 4 & 3 \\ 3 & 4 & 1 & 2 \\ 4 & 3 & 2 & 1 \end{bmatrix} \text{ and } \begin{bmatrix} 1 & 2 & 3 & 4 \\ 3 & 4 & 1 & 2 \\ 4 & 3 & 2 & 1 \\ 2 & 1 & 4 & 3 \end{bmatrix}. \tag{3}$$

A pair of Latin squares is said to be orthogonal if the n^2 pairs formed by juxtaposing the two arrays are all distinct. For example, the two Latin squares

$$\begin{bmatrix} 3 & 2 & 1 \\ 2 & 1 & 3 \\ 1 & 3 & 2 \end{bmatrix} \quad \begin{bmatrix} 2 & 3 & 1 \\ 1 & 2 & 3 \\ 3 & 1 & 2 \end{bmatrix} \tag{4}$$

are orthogonal.

A normalized, or reduced, Latin square is a Latin square with the first row and column given by $\{1, 2, \ldots, n\}$. General FORMULAS for the number of *normalized* $n \times n$ Latin squares $L(n, n)$ are given by Nechvatal (1981), Gessel (1987), and Shao and Wei (1992). The *total* number of Latin squares $N(n, n)$ of order n can then be computed from

$$N(n, n) = n!(n-1)!L(n, n). \tag{5}$$

The numbers of normalized Latin squares of order $n = 1, 2, ...,$ are 1, 1, 1, 4, 56, 9408, ... (Sloane's A000315). McKay and Rogoyski (1995) give the number of normalized LATIN RECTANGLES $L(k, n)$ for $n = 1, ..., 10$, as well as estimates for $L(n, n)$ with $n = 11, 12, ..., 15$.

n	$L(n, n)$
11	5.36×10^{33}
12	1.62×10^{44}
13	2.51×10^{56}
14	2.33×10^{70}
15	1.5×10^{86}

Latitude

The latitude of a point on a sphere is the elevation of the point from the plane of the equator. The latitude δ is related to the colatitude (the polar angle in spherical coordinates) by $\delta = \phi - 90°$. More generally, the latitude of a point on an ellipsoid is the angle between a line perpendicular to the surface of the ellipsoid at the given point and the plane of the equator (Snyder 1987).

The equator therefore has latitude 0°, and the north and south poles have latitude ±90°, respectively. Latitude is also called geographic latitude or geodetic latitude in order to distinguish it from several subtly different varieties of auxiliary latitudes.

The shortest distance between any two points on a sphere is the so-called great circle distance, which can be directly computed from the latitudes and longitudes of the two points.

Lattice

A lattice is a system K such that $\forall A \in K, A \subset A$, and if $A \subset B$ and $B \subset A$, then $A = B$, where $\subset$ means "is included in." Lattices offer a natural way to formalize and study the ordering of objects using a general concept known as the poset (partially ordered set). The study of lattices is called lattice theory. Note that this type of lattice is distinct from the regular array of points known as a point lattice (or informally as a mesh or grid).

The following inequalities hold for any lattice:

$$(x \wedge y) \vee (x \wedge z) \leq x \wedge (y \vee z)$$

$$x \vee (y \wedge z) \leq (x \vee y) \wedge (x \vee z)$$

$$(x \wedge y) \vee (y \wedge z) \vee (z \wedge x) \leq (x \vee y) \wedge (y \vee z) \wedge (z \vee x)$$

$$(x \wedge y) \vee (x \wedge z) \leq x \wedge (y \vee (x \wedge z))$$

(Grätzer 1971, p. 35). The first three are the distributive inequalities, and the last is the modular identity.

Lattice Graph

The lattice graph with n nodes on a side is denoted $L(n)$.

See also TRIANGULAR GRAPH

Lattice Groups

In the plane, there are 17 lattice groups, eight of which are pure translation. In $\mathbb{R}^3$, there are 32 POINT GROUPS and 230 SPACE GROUPS. In $\mathbb{R}^4$, there are 4783 space lattice groups.

See also POINT GROUPS, SPACE GROUPS, WALLPAPER GROUPS

Lattice Invariant

INVARIANT (ELLIPTIC FUNCTION)

Lattice Path

A path composed of connected horizontal and vertical line segments, each passing between adjacent LATTICE POINTS. A lattice path is therefore a SEQUENCE of points $P_0, P_1, ..., P_n$ with $n \geq 0$ such that each P_i is a LATTICE POINT and P_{i+1} is obtained by offsetting one unit east (or west) or one unit north (or south).

The number of paths of length $a+b$ from the ORIGIN (0,0) to a point $(a,\ b)$ which are restricted to east and north steps is given by the BINOMIAL COEFFICIENT $\binom{a+b}{a}$.

Lattice Point

A POINT at the intersection of two or more grid lines in a POINT LATTICE.

See also POINT LATTICE

Lattice Polygon

A POLYGON whose vertices are points of a POINT LATTICE. Regular lattice n-gons exists only for $n=3$, 4, and 6 (Schoenberg 1937, Klamkin and Chrestenson 1963, Maehara 1993). A lattice n-gon in the plane can be equiangular to a regular polygon only for $n=4$ and 8 (Scott 1987, Maehara 1993).

Maehara (1993) presented a NECESSARY and SUFFICIENT condition for a polygon to be angle-equivalent to a lattice polygon in $\mathbb{R}^n$. In addition, Maehara (1993) proved that $\cos^2(\Sigma_{\theta \in S}\ \theta)$ is a RATIONAL NUMBER for any collection S of interior angles of a lattice polygon.

LatticeReduce

LLL ALGORITHM

Lattice Reduction

The process of finding a reduced set of basis vectors for a given LATTICE having certain special properties. Lattice reduction algorithms are used in a number of modern number theoretical applications, including in the discovery of a SPIGOT ALGORITHM for PI. Although determining the shortest basis is possibly an NP-COMPLETE PROBLEM, algorithms such as the LLL ALGORITHM can find a short basis in polynomial time with guaranteed worst-case performance.

The LLL ALGORITHM of lattice reduction is implemented in *Mathematica* using the function `LatticeReduce`. `Recognize[x, n, t]` in the *Mathematica* add-on package ``NumberTheory`Recognize` `` (which can be loaded with the command ``<<NumberTheory` ``) also calls this routine in order to find a polynomial of degree at most n in a variable t such that x is an approximate zero of the polynomial.

When used to find integer relations, a typical input to the algorithm consists of an augmented $n\times n$ IDENTITY MATRIX with the entries in the last column consisting of the n elements (multiplied by a large positive constant w to penalize vectors that do not sum to zero) between which the relation is sought. For example, if an equality OF THE FORM

$$a_1x+a_2y+a_3z=0$$

is known to exist, then doing a lattice reduction on the matrix

$$m=\begin{bmatrix}1 & 0 & 0 & wx\\ 0 & 1 & 0 & wy\\ 0 & 0 & 1 & wz\end{bmatrix}$$

will produce a new matrix in which one or more entries in the last column being close to zero. This row then gives the coefficients $\{a_1, a_2, a_3, 0\}$ of the identity. An example lattice reduction calculation is illustrated in both Borwein and Corless (1999) and Borwein and Lisonek.

Lattice Sum

Cubic lattice sums include the following:

$$b_2(2s)\equiv\sum_{i,\,j=-\infty}^{\infty}{}' \frac{(-1)^{i+j}}{(i^2+j^2)^s} \tag{1}$$

$$b_3(2s)\equiv\sum_{i,\,j,\,k=-\infty}^{\infty}{}' \frac{(-1)^{i+j+k}}{(i^2+j^2+k^2)^s} \tag{2}$$

$$b_n(2s)\equiv\sum_{k_1,\,\ldots,\,k_n=-\infty}^{\infty}{}' \frac{(-1)^{k_1+\ldots+k_n}}{(k_1^2+\ldots+k_n^2)^s}, \tag{3}$$

where the prime indicates that summation over the original $(0,0)$, $(0,0,0)$, ... is excluded (Borwein and Borwein 1986, p. 288).

As shown in Borwein and Borwein (1987, pp. 288–01), these have closed forms for even n

$$b_2(2s)=-4\beta(s)\eta(s) \tag{4}$$

$$b_4(2s)=-8\eta(s)\eta(s-1) \tag{5}$$

$$b_8(2s)=-16\zeta(s)\eta(s-3),\quad \text{for } \Re[s]>1 \tag{6}$$

where $\beta(z)$ is the DIRICHLET BETA FUNCTION, $\eta(z)$ is the DIRICHLET ETA FUNCTION, and $\zeta(z)$ is the RIEMANN ZETA FUNCTION. The lattice sums evaluated at $s=1$ are called the MADELUNG CONSTANTS. An additional form for $b_2(2s)$ is given by

$$b_2(2s)=\sum_{n=1}^{\infty}\frac{(-1)^n r_2(n)}{n^s} \tag{7}$$

for $\Re[s]>1/3$, where $r_2(n)$ is the SUM OF SQUARES FUNCTION, i.e., the number of representations of n by two squares (Borwein and Borwein 1986, p. 291). Borwein and Borwein (1986) prove that $b_8(2)$ converges (the closed form for $b_8(2s)$ above does not apply for $s=1$), but its value has not been computed. A number of other related DOUBLE SERIES can be evaluated analytically.

For hexagonal sums, Borwein and Borwein (1987, p. 292) give

$$h_2(2s) \equiv \frac{4}{3} \sum_{m,\ n=-\infty}^{\infty} \times \frac{\sin[(n+1)\theta]\sin[(m+1)\theta] - \sin(n\theta)\sin[(m-1)\theta]}{\left[\left(n+\frac{1}{2}m\right)^2 + 3\left(\frac{1}{2}m\right)^2\right]^s}, \quad (8)$$

where $\theta = 2\pi/3$. This MADELUNG CONSTANT is expressible in closed form for $s = 1$ as

$$h_2(2) = \pi \ln 3\sqrt{3}. \quad (9)$$

Other interesting analytic lattice sums are given by

$$\sum_{k,\ m,\ n=-\infty}^{\infty} \frac{(-1)^{k+m+n}}{\left[\left(k+\frac{1}{6}\right)^2\left(m+\frac{1}{6}\right)^2\left(n+\frac{1}{6}\right)^2\right]^s} = 12^s \beta(2s-1), \quad (10)$$

giving the special case

$$\sum_{k,\ m,\ n=-\infty}^{\infty} \frac{(-1)^{k+m+n}}{\left[\left(k+\frac{1}{6}\right)^2\left(m+\frac{1}{6}\right)^2\left(n+\frac{1}{6}\right)^2\right]^{1/2}} = \sqrt{3} \quad (11)$$

(Borwein and Borwein 1986, p. 303), and

$$\sum_{k,\ m,\ n=-\infty}^{\infty} \frac{(-1)^{k+m+n+1}}{(|k|+|m|+|n|)^s} = 2\eta(s) + 4\eta(s-2) \quad (12)$$

(Borwein and Borwein 1986, p. 305).

Lattice Theory

Lattice theory is the study of sets of objects known as LATTICES. It is an outgrowth of the study of BOOLEAN ALGEBRAS, and provides a framework for unifying the study of classes or ordered sets in mathematics. The study of lattice theory was given a great boost by a series of papers and subsequent textbook written by Birkhoff (1967).

Laurent Polynomial

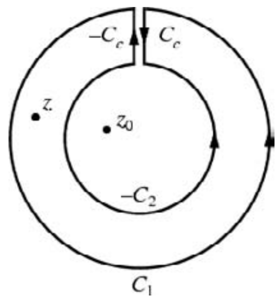
A Laurent polynomial with COEFFICIENTS in the FIELD $\mathbb{F}$ is an algebraic object that is typically expressed in the form

$$\ldots + a_{-n}t^{-n} + a_{-(n-1)}t^{-(n-1)} + \ldots$$
$$+ a_{-1}t^{-1} + a_0 + a_1 t + \ldots + a_n t^n + \ldots,$$

where the a_i are elements of $\mathbb{F}$, and only finitely many of the a_i are NONZERO. A Laurent polynomial is an algebraic object in the sense that it is treated as a POLYNOMIAL except that the indeterminant "t" can also have NEGATIVE POWERS.

Expressed more precisely, the collection of Laurent polynomials with COEFFICIENTS in a FIELD $\mathbb{F}$ form a RING, denoted $\mathbb{F}[t, t^{-1}]$, with RING operations given by componentwise addition and multiplication according to the relation

$$at^n \cdot bt^m = abt^{n+m}$$



for all n and m in the INTEGERS. Formally, this is equivalent to saying that $\mathbb{F}[t, t^{-1}]$ is the GROUP RING of the INTEGERS and the FIELD $\mathbb{F}$. This corresponds to $\mathbb{F}[t]$ (the POLYNOMIAL ring in one variable for $\mathbb{F}$) being the GROUP RING or MONOID ring for the MONOID of natural numbers and the FIELD $\mathbb{F}$.

Laurent Series

Let there be two circular contours C_2 and C_1, with the radius of C_1 larger than that of C_2. Let z_0 be interior to C_1 and C_2, and z be between C_1 and C_2. Now create a cut line C_c between C_1 and C_2, and integrate around the path $C \equiv C_1 + C_c - C_2 - C_c$, so that the plus and minus contributions of C_c cancel one another, as illustrated above. From the CAUCHY INTEGRAL FORMULA,

$$f(z) = \frac{1}{2\pi i} \int_C \frac{f(z')}{z' - z}\, dz'$$

$$= \frac{1}{2\pi i} \int_{C_1} \frac{f(z')}{z' - z}\, dz' + \frac{1}{2\pi i} \int_{C_c} \frac{f(z')}{z' - z}\, dz'$$

$$- \frac{1}{2\pi i} \int_{C_1} \frac{f(z')}{z' - z} - \frac{1}{2\pi i} \int_{C_c} \frac{f(z')}{z' - z}\, dz'$$

$$= \frac{1}{2\pi i} \int_{C_1} \frac{f(z')}{z' - z}\, dz' - \frac{1}{2\pi i} \int_{C_2} \frac{f(z')}{z' - z}\, dz'. \qquad (1)$$

Now, since contributions from the cut line in opposite directions cancel out,

$$f(z) = \frac{1}{2\pi i} \int_{C_1} \frac{f(z')}{(z' - z_0) - (z - z_0)}\, dz'$$
$$- \frac{1}{2\pi i} \int_{C_2} \frac{f(z')}{(z' - z_0) - (z - z_0)}\, dz'$$

$$= \frac{1}{2\pi i} \int_{C_1} \frac{f(z')}{(z' - z_0)\left(1 - \frac{z - z_0}{z' - z_0}\right)}\, dz'$$
$$- \frac{1}{2\pi i} \int_{C_2} \frac{f(z')}{(z - z_0)\left(\frac{z' - z_0}{z - z_0} - 1\right)}\, dz'$$

$$= \frac{1}{2\pi i} \int_{C_1} \frac{f(z')}{(z' - z_0)\left(1 - \frac{z - z_0}{z' - z_0}\right)}\, dz'$$
$$- \frac{1}{2\pi i} \int_{C_2} \frac{f(z')}{(z - z_0)\left(1 - \frac{z' - z_0}{z - z_0}\right)}\, dz' \qquad (2)$$

For the first integral, $|z' - z_0| > |z - z_0|$. For the second, $|z' - z_0| < |z - z_0|$. Now use the TAYLOR EXPANSION (valid for $|t| < 1$)

$$\frac{1}{1 - t} = \sum_{n=0}^{\infty} t^n \qquad (3)$$

to obtain

$$f(z) = \frac{1}{2\pi i} \left[\int_{C_1} \frac{f(z')}{z' - z_0} \sum_{n=0}^{\infty} \left(\frac{z - z_0}{z - z_0}\right)^n dz' \right.$$
$$\left. + \int_{C_2} \frac{f(z')}{z - z_0} \sum_{n=0}^{\infty} \left(\frac{z' - z_0}{z - z_0}\right)^n dz' \right]$$

$$= \frac{1}{2\pi i} \sum_{n=0}^{\infty} (z - z_0)^n \int_{C_1} \frac{f(z')}{(z' - z_0)^{n+1}}\, dz'$$
$$+ \frac{1}{2\pi i} \sum_{n=0}^{\infty} (z - z_0)^{-n-1} \int_{C_2} (z' - z_0)^n f(z')\, dz'$$

$$= \frac{1}{2\pi i} \sum_{n=0}^{\infty} (z - z_0)^n \int_{C_1} \frac{f(z')}{(z' - z_0)^{n+1}}\, dz'$$
$$+ \frac{1}{2\pi i} \sum_{n=1}^{\infty} (z - z_0)^{-n} \int_{C_2} (z' - z_0)^{n+1} f(z')\, dz', \qquad (4)$$

where the second term has been re-indexed. Re-indexing again,

$$f(z) = \frac{1}{2\pi i} \sum_{n=0}^{\infty} (z - z_0)^n \int_{C_1} \frac{f(z')}{(z' - z_0)^{n+1}}\, dz'$$
$$+ \frac{1}{2\pi i} \sum_{n=-\infty}^{-1} (z - z_0) \int_{C_2} \frac{f(z')}{(z' - z_0)^{n+1}}\, dz'. \qquad (5)$$

Now, use the CAUCHY INTEGRAL THEOREM, which requires that any CONTOUR INTEGRAL of a function which encloses no POLES has value 0. But $1/(z' - z_0)^{n+1}$ is never singular inside C_2 for $n \geq 0$, and $1/(z' - z_0)^{n+1}$ is never singular inside C_1 for $n \leq -1$. Similarly, there are no POLES in the closed cut $C_c - C_c$. We can therefore replace C_1 and C_2 in the above integrals by C without altering their values, so

$$f(z) = \frac{1}{2\pi i} \sum_{n=0}^{\infty} (z - z_0)^n \int_C \frac{f(z')}{(z' - z_0)^{n+1}}\, dz'$$
$$+ \frac{1}{2\pi i} \sum_{n=-\infty}^{-1} (z - z_0)^n \int_C \frac{f(z')}{(z' - z_0)^{n+1}}\, dz'$$
$$= \frac{1}{2\pi i} \sum_{n=-\infty}^{\infty} (z - z_0)^n \int_C \frac{f(z')}{(z' - z_0)^{n+1}}\, dz'$$
$$\equiv \sum_{n=-\infty}^{\infty} a_n (z - z_0)^n. \qquad (6)$$

The only requirement on C is that it encloses z, so we are free to choose any contour γ that does so. The

RESIDUES a_n are therefore defined by

$$a_n \equiv \frac{1}{2\pi i} \int_\gamma \frac{f(z')}{(z'-z_0)^{n+1}}\, dz'. \tag{7}$$

Lauricella Functions

This entry contributed by RONALD M. AARTS

Lauricella functions are generalizations of the Gauss hypergeometric functions to multiple variables. Four such generalizations were investigated by Lauricella (1893), and more fully by Appell and Kampé de Fériet (1926, p. 117). Let n be the number of variables, then the Lauricella functions are defined by

$$F_A^{(n)}(a,\ b_1,\ \ldots,\ b_n;\ c_1,\ \ldots,\ c_n;\ x_1,\ \ldots x_n)$$
$$= \sum \frac{(a,\ m_1+\ldots+m_n)(b_1,\ m_1)\cdots(b_n,\ m_n)x_1^{m_1}\cdots x_n^{m_n}}{(c_1,\ m_1)\cdots(c_n,\ m_n)m_1!\cdots m_n!} \tag{1}$$

$$F_B^{(n)}(a_1,\ \ldots,\ a_n,\ b_1,\ \ldots,\ b_n;\ c;\ x_1,\ \ldots,\ x_n)$$
$$= \sum \frac{(a_1,\ m_1)\cdots(a_n,\ m_n)(b_1,\ m_1)\cdots(b_n,\ m_n)x_1^{m_1}\cdots x_n^{m_n}}{(c,\ m_1+\ldots m_n)m_1!\cdots m_n!} \tag{2}$$

$$F_C^{(n)}(a,\ b;\ c_1,\ \ldots,\ c_n;\ x_1,\ \ldots,\ x_n)$$
$$= \sum \frac{(a_1,\ m_1+\ldots m_n)(b,\ m_1+\ldots m_n)x_1^{m_1}\cdots x_n^{m_n}}{(c_1,\ m_1)\cdots(c_n,\ m_n)m_1!\cdots m_n!} \tag{3}$$

$$F_D^{(n)}(a,\ b_1,\ \ldots,\ b_n;\ c;\ x_1,\ldots,\ x_n)$$
$$= \sum \frac{(a,\ m_1+\ldots+m_n)(b_1,\ m_1)\cdots(b_n,\ m_n)x_1^{m_1}\cdots x_n^{m_n}}{(c,\ m_1+\ldots m_n)m_1!\cdots m_n!}. \tag{4}$$

If $n=2$, then these functions reduce to the APPELL HYPERGEOMETRIC FUNCTIONS F_2, F_3, F_4, and F_1, respectively. If $n=1$, all four become the Gauss hypergeometric function ${}_2F_1$ (Exton 1978, p. 29).

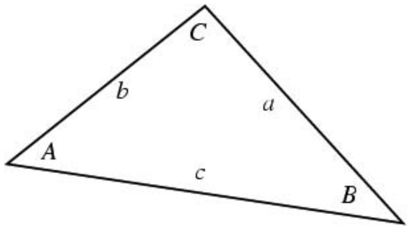
Law

A law is a mathematical statement which always holds true. Whereas "laws" in physics are generally experimental observations backed up by theoretical underpinning, laws in mathematics are generally THEOREMS which can formally be proven true under the stated conditions. However, the term is also sometimes used in the sense of an empirical observation, e.g., BENFORD'S LAW.

See also ABSORPTION LAW, BENFORD'S LAW, CONTRADICTION LAW, DE MORGAN'S DUALITY LAW, DE MORGAN'S LAWS, ELLIPTIC CURVE GROUP LAW, EXCLUDED MIDDLE LAW, EXPONENT LAWS, GIRKO'S CIRCULAR LAW, LAW OF COSINES, LAW OF SINES, LAW OF TANGENTS, LAW OF TRULY LARGE NUMBERS, MORRIE'S LAW, PARALLELOGRAM LAW, PLATEAU'S LAWS, QUADRATIC RECIPROCITY LAW, STRONG LAW OF LARGE NUMBERS, STRONG LAW OF SMALL NUMBERS, SYLVESTER'S INERTIA LAW, TRICHOTOMY LAW, VECTOR TRANSFORMATION LAW, WEAK LAW OF LARGE NUMBERS, ZIPF'S LAW



Law of Anomalous Numbers

BENFORD'S LAW

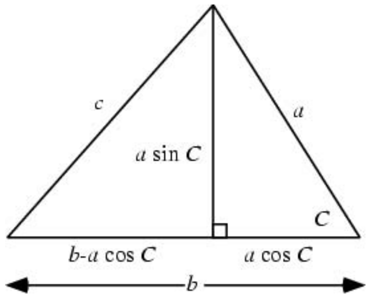
Law of Cancellation

CANCELLATION LAW

Law of Cosines

Let a, b, and c be the lengths of the legs of a TRIANGLE opposite ANGLES A, B, and C. Then the law of cosines states

$$c^2 = a^2 + b^2 - 2ab \cos C. \quad (1)$$



This law can be derived in a number of ways. The definition of the DOT PRODUCT incorporates the law of cosines, so that the length of the VECTOR from $\mathbf{X}$ to $\mathbf{Y}$ is given by

$$|\mathbf{X}-\mathbf{Y}|^2 = (\mathbf{X}-\mathbf{Y}) \cdot (\mathbf{X}-\mathbf{Y}) \quad (2)$$

$$= \mathbf{X} \cdot \mathbf{X} - 2\mathbf{X} \cdot \mathbf{Y} + \mathbf{Y} \cdot \mathbf{Y} \quad (3)$$

$$= |\mathbf{X}|^2 + |\mathbf{Y}|^2 - 2|\mathbf{X}||\mathbf{Y}|\cos\theta, \quad (4)$$

where θ is the ANGLE between $\mathbf{X}$ and $\mathbf{Y}$.

The formula can also be derived using a little geometry and simple algebra. From the above diagram,

$$c^2 = (a \sin C)^2 + (b - a \cos C)^2$$

$$= a^2 \sin^2 C + b^2 - 2ab \cos C + a^2 \cos^2 C$$

$$= a^2 + b^2 - 2ab \cos C. \quad (5)$$

The law of cosines for the sides of a SPHERICAL TRIANGLE states that

$$\cos a = \cos b \cos c + \sin b \sin c \cos A \quad (6)$$

$$\cos b = \cos c \cos a + \sin c \sin a \cos B \quad (7)$$

$$\cos c = \cos a \cos b + \sin a \sin b \cos C \quad (8)$$

(Beyer 1987). The law of cosines for the angles of a SPHERICAL TRIANGLE states that

$$\cos A = -\cos B \cos C + \sin B \sin C \cos a \quad (9)$$

$$\cos B = -\cos C \cos A + \sin C \sin A \cos b \quad (10)$$

$$\cos C = -\cos A \cos B + \sin A \sin B \cos c \quad (11)$$

(Beyer 1987).
For similar triangles, a generalized law of cosines is given by

$$aa' = bb' + cc' - (bc' + b'c)\cos A \quad (12)$$

(Lee 1997). Furthermore, consider an arbitrary TETRAHEDRON $A_1A_2A_3A_4$ with triangles $T_1 = \Delta A_2A_3A_4$, $T_2 = \Delta A_1A_3A_4$, $T_3 = \Delta A_1A_2A_4$, and $T_4 = A_1A_2A_3$. Let the areas of these triangles be s_1, s_2, s_3, and s_4, respectively, and denote the DIHEDRAL ANGLE with respect to T_i and T_j for $i \neq j = 1, 2, 3, 4$ by θ_{ij}. Then

$$s_k = \sum_{\substack{j \neq k \\ 1 \leq i \leq 4}} s_i \cos \theta_{ki}, \quad (13)$$

which gives the law of cosines in a tetrahedron,

$$s_k^2 = \sum_{\substack{i \neq k \\ 1 \leq j \leq 4}} s_j^2 - 2 \sum_{\substack{i,\, j \neq k \\ 1 \leq i,j \leq 4}} s_i s_j \cos \theta_{ij} \quad (14)$$

(Lee 1997). A corollary gives the nice identity

$$s_1s_1' = s_2s_2' + s_3s_3' + s_4s_4' - (s_2s_3' + s_2's_3)\cos\theta_{23}$$

$$-(s_3s_4' + s_3's_4)\cos\theta_{34} - (s_2s_4' + s_2's_4)\cos\theta_{24} \quad (15)$$

Law of Truly Large Numbers

With a large enough sample, any outrageous thing is likely to happen (Diaconis and Mosteller 1989). Littlewood (1953) considered an event which occurs one in a million times to be "surprising." Taking this definition, close to 100,000 surprising events are "expected" each year in the United States alone and, in the world at large, "we can be absolutely sure that we will see incredibly remarkable events" (Diaconis and Mosteller 1989).

Lax Pair

A pair of linear OPERATORS L and A associated with a given PARTIAL DIFFERENTIAL EQUATION which can be used to solve the equation. However, it turns out to be very difficult to find the L and A corresponding to a given equation, so it is actually simpler to postulate a given L and A and determine to which PARTIAL DIFFERENTIAL EQUATION they correspond (Infeld and Rowlands 2000).

Layer

P-LAYER

LCM

LEAST COMMON MULTIPLE

Leading Digit Phenomenon

BENFORD'S LAW

Leading Order Analysis

A procedure for determining the behavior of an nth order ORDINARY DIFFERENTIAL EQUATION at a REMOVABLE SINGULARITY without actually solving the equation. Consider

$$\frac{d^n y}{dz^n} = F\left(\frac{d^{n-1}y}{dz^{n-1}}, \ldots, \frac{dy}{dx}, y, z\right), \tag{1}$$

where F is ANALYTIC in z and rational in its other arguments. Proceed by making the substitution

$$y(z) \equiv a(z - z_0)^\alpha \tag{2}$$

with $\alpha < 1$. For example, in the equation

$$\frac{d^2 y}{dz^2} = 6y^2 + Ay, \tag{3}$$

making the substitution gives

$$a\alpha(\alpha-1)(z-z_0)^{\alpha-2} = 6a^2(z-z_0)^{2\alpha} + Aa(az-z_0)^\alpha. \tag{4}$$

The most singular terms (those with the most NEGATIVE exponents) are called the "dominant balance terms," and must balance exponents and COEFFICIENTS at the SINGULARITY. Here, the first two terms are dominant, so

$$\alpha - 2 = 2\alpha \Rightarrow \alpha = -2 \tag{5}$$

$$6a = 6a^2 \Rightarrow a = 1, \tag{6}$$

and the solution behaves as $y(z) = (z - z_0)^{-2}$. The behavior in the NEIGHBORHOOD of the SINGULARITY is given by expansion in a LAURENT SERIES, in this case,

$$y(z) = \sum_{j=0}^\infty a_j (z - z_0)^{j-2}. \tag{7}$$

Plugging this series in yields

$$\sum_{j=0}^\infty a_j (j-2)(j-3)(z-z_0)^{j-4}$$

$$= 6 \sum_{j=0}^\infty \sum_{k=0}^\infty a_j a_k (z-z_0)^{j+k-4} + A \sum_{j=0}^\infty a_j (z-z_0)^{j-2}. \tag{8}$$

This gives RECURRENCE RELATIONS, in this case with a_6 arbitrary, so the $(z-z_0)^6$ term is called the resonance or KOVALEVSKAYA EXPONENT. At the resonances, the COEFFICIENT will always be arbitrary. If no resonance term is present, the POLE present is not ordinary, and the solution must be investigated using a PSI FUNCTION.

Least Bound

SUPREMUM

Least Common Multiple

The least common multiple of two numbers a and b, denoted LCM(a, b) or $[a, b]$, is the smallest number m for which there exist positive integers n_a and n_b such that

$$n_a a = n_b b = m. \tag{1}$$

The least common multiple LCM($a, b, c, \ldots$) of more than two numbers is similarly defined. The plot above shows LCM(1, r) for rational $r = m/n$, which is equivalent to the NUMERATOR of the reduced form of m/n.

The least common multiple of a, b, c, ..., is denoted LCM[a, b, c, ...] in *Mathematica*.

The least common multiple of two numbers a and b can be obtained by finding the PRIME FACTORIZATION of each

$$a = p_1^{a_1} \cdots p_n^{a_n} \tag{2}$$

$$b = p_1^{b_1} \cdots p_n^{b_n}, \tag{3}$$

where the p_is are all PRIME FACTORS of a and b, and if p_i does not occur in one factorization, then the corresponding exponent is taken as 0. The least common multiple is then given by

$$\mathrm{LCM}(a, b) = \prod_{i=1}^{n} p_i^{\max(a_i, b_i)}. \tag{4}$$

For example, consider LCM(12, 30).

$$12 = 2^2 \cdot 3^1 \cdot 5^0 \tag{5}$$

$$30 = 2^1 \cdot 3^1 \cdot 5^1, \tag{6}$$

so

$$LCM(12, 30) = 2^2 \cdot 3^1 \cdot 5^1 = 60. \tag{7}$$

Let m be a common multiple of a and b so that

$$m = ha = kb. \tag{8}$$

Write $a=a_1$ GCD(a, b) and $b=b_1$ GCD(a, b), where a_1 and b_1 are RELATIVELY PRIME by definition of the GREATEST COMMON DIVISOR $GCD(a_1, b_1)=1$. Then $ha_1=kb_1$, and from the DIVISION LEMMA (given that ha_1 is DIVISIBLE by b_1 and $\mathrm{GCD}(b_1, a_1)=1$), we have h is DIVISIBLE by b_1, so

$$h=nb_1 \tag{9}$$

$$m=ha=nb_1a=n\,\frac{ab}{\mathrm{GCD}(a, b)}. \tag{10}$$

The smallest m is given by $n = 1$,

$$\mathrm{LCM}(a, b)=\frac{ab}{\mathrm{GCD}(a, b)}, \tag{11}$$

so

$$\mathrm{GCD}(a, b)\mathrm{LCM}(a, b)=ab \tag{12}$$

The LCM is IDEMPOTENT

$$\mathrm{LCM}(a, a)=a \tag{13}$$

COMMUTATIVE

$$\mathrm{LCM}(a, b)=\mathrm{LCM}(b, a), \tag{14}$$

ASSOCIATIVE

$$\begin{aligned}\mathrm{LCM}(a, b, c)&=\mathrm{LCM}(\mathrm{LCM}(a, b), c)\\&=\mathrm{LCM}(a, \mathrm{LCM}(b, c)),\end{aligned} \tag{15}$$

DISTRIBUTIVE

$$\mathrm{LCM}(ma, mb, mc)=m\,\mathrm{LCM}(a, b, c), \tag{16}$$

and satisfies the ABSORPTION LAW

$$\mathrm{GCD}(a, \mathrm{LCM}(a, b))=a. \tag{17}$$

It is also true that

$$\begin{aligned}\mathrm{LCM}(ma, mb)&=\frac{\mathrm{GCD}(ma)\mathrm{GCD}(mb)}{\mathrm{GCD}(ma, mb)}=m\,\frac{ab}{\mathrm{GCD}(a, b)}\\&=m\,\mathrm{LCM}(a, b).\end{aligned} \tag{18}$$

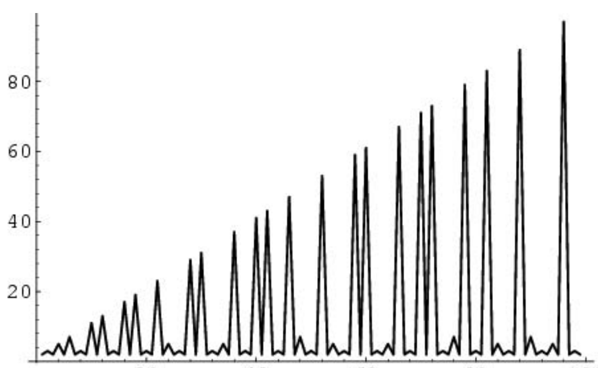
Least Divisor



LEAST PRIME FACTOR

Least Period

The smallest n for which a point x_0 is a PERIODIC POINT of a function f so that $f^n(x_0)=x_0$. For example, for the FUNCTION $f(x)=-x$, all points x have period 2 (including $x=0$). However, $x=0$ has a *least* period of 1. The analogous concept exists for a PERIODIC SEQUENCE, but not for a PERIODIC FUNCTION. The least period is also called the exact period.

Least Prime Factor

Let $n>1$ be any integer and let LD(n) be the least integer greatest than 1 that divides n. Then LD(n) is a prime number, and if n is not prime, then $[\mathrm{LD}(n)]^2\le n$ (Séroul 2000, p. 7).

For an INTEGER $n\ge 2$, let lpf(x) denote the LEAST PRIME FACTOR of n, i.e., the number p_1 in the factorization

$$n = p_1^{a_1} \cdots p_k^{a_k},$$

with $p_i < p_j$ for $i < j$. For $n = 2, 3, ...$, the first few are 2, 3, 2, 5, 2, 7, 2, 3, 2, 11, 2, 13, 2, 3, ... (Sloane's A020639). The above plot of the least prime factor function can be seen to resemble a jagged terrain of mountains, which leads to the appellation of "TWIN PEAKS" to a PAIR of INTEGERS (x, y) such that

1. $x < y$,
2. $\mathrm{lpf}(x) = \mathrm{lpf}(y)$,
3. For all z, $x < z < y$ IMPLIES $\mathrm{lpf}(z) < \mathrm{lpf}(x)$.

The least *multiple* prime factors for SQUAREFUL integers are 2, 2, 3, 2, 2, 3, 2, 2, 5, 3, 2, 2, 2, ... (Sloane's A046027).

Erdos *et al.* (1993) consider the least prime factor of the BINOMIAL COEFFICIENTS, and define what they term GOOD BINOMIAL COEFFICIENTS and EXCEPTIONAL BINOMIAL COEFFICIENTS. They also conjecture that

$$\mathrm{lpf}\binom{N}{k} \leq \max(N/k,\ 29). \qquad (1)$$

Least Squares Fitting

A mathematical procedure for finding the best fitting curve to a given set of points by minimizing the sum of the squares of the offsets ("the residuals"rpar; of the points from the curve. The sum of the *squares* of the offsets is used instead of the offset absolute values because this allows the residuals to be treated as a continuous differentiable quantity. However, because squares of the offsets are used, outlying points can have a disproportionate effect on the fit, a property which may or may not be desirable depending on the problem at hand.

In practice, the *vertical* offsets from a line are almost always minimized instead of the *perpendicular* offsets. This allows uncertainties of the data points along the x- and y-axes to be incorporated simply, and also provides a much simpler analytic form for the fitting parameters than would be obtained using a fit based on perpendicular distances. In addition, the fitting technique can be easily generalized from a best-fit *line* to a best-fit *polynomial* when sums of vertical distances are used (which is not the case using perpendicular distances). For a reasonable number of noisy data points, the difference between vertical and perpendicular fits is quite small.

The *linear* least squares fitting technique is the simplest and most commonly applied form of LINEAR REGRESSION and provides a solution to the problem of finding the best fitting *straight* line through a set of points. In fact, if the functional relationship between the two quantities being graphed is known to within additive or multiplicative constants, it is common practice to transform the data in such a way that the resulting line *is* a straight line, say by plotting T vs. $\sqrt{\ell}$ instead of T vs. ℓ in the case of analyzing the period T of a pendulum as a function of its length l. For this reason, standard forms for EXPONENTIAL, LOGARITHMIC, and POWER laws are often explicitly computed. The formulas for linear least squares fitting were independently derived by Gauss and Legendre.

For NONLINEAR LEAST SQUARES FITTING to a number of unknown parameters, linear least squares fitting may be applied iteratively to a linearized form of the function until convergence is achieved. Depending on the type of fit and initial parameters chosen, the nonlinear fit may have good or poor convergence properties. If uncertainties (in the most general case, error ellipses) are given for the points, points can be weighted differently in order to give the high-quality points more weight.

The residuals of the best-fit line for a set of n points using *unsquared perpendicular* distances d_i of points (x_i, y_i) are given by

$$R_\perp \equiv \sum_{i=1}^{n} d_i. \qquad (1)$$

Since the perpendicular distance from a line $y = a + bx$ to point i is given by

$$d_i = \frac{|y_i - (a + bx_i)|}{\sqrt{1 + b^2}}, \qquad (2)$$

the function to be minimized is

$$R_\perp \equiv \sum_{i=1}^{n} \frac{|y_i - (a + bx_i)|}{\sqrt{1 + b^2}}. \qquad (3)$$

Unfortunately, because the absolute value function does not have continuous derivatives, minimizing $R_\perp$ is not amenable to analytic solution. However, if the *square* of the perpendicular distances

$$R_\perp^2 \equiv \sum_{i=1}^{n} \frac{[y_i - (a + bx_i)]^2}{1 + b^2} \qquad (4)$$

is minimized instead, the problem can be solved in closed form. $R_\perp^2$ is a minimum when (suppressing the indices)

$$\frac{\partial R_\perp^2}{\partial a} = \frac{2}{1 + b^2} \sum [y - (a + bx)](-1) = 0 \qquad (5)$$

and

$$\frac{\partial R_\perp^2}{\partial b} = \frac{2}{1 + b^2} \sum [y - (a + bx)](-x) + \sum \frac{[y - (a + bx)]^2(-1)(2b)}{(1 + b^2)^2} = 0. \qquad (6)$$

The former gives

$$a = \frac{\sum y - b \sum x}{n} = \bar{y} - b\bar{x}, \qquad (7)$$

and the latter

$$(1 + b^2) \sum [y - (a + bx)]x + b \sum [y - (a + bx)]^2 = 0. \qquad (8)$$

But

$$[y - (a + bx)]^2 = y^2 - 2(a + bx)y + (a + bx)^2 = y^2 - 2ay - 2bxy + a^2 + 2abx + b^2x^2, \qquad (9)$$

so (8) becomes

$$(1 + b^2)\left(\sum xy - a \sum x - b \sum x^2\right) + b\left(\sum y^2 - 2a \sum y - 2b \times \sum xy + a^2 \sum 1 + 2ab \sum x + b^2 \sum x^2\right) = 0 \qquad (10)$$

$$[(1 + b^2)(-b) + b(b^2)] \sum x^2 + [(1 + b^2) - 2b^2] \sum xy + b \sum y^2 + [-a(1 + b^2) + 2ab^2] \sum x - 2ab \sum y + ba^2 \sum 1 = 0 \qquad (11)$$

$$-b \sum x^2 + (1 - b^2) \sum xy + b \sum y^2 + a(b^2 - 1) \sum x - 2ab \sum y + ba^2 n = 0. \qquad (12)$$

Plugging (7) into (12) then gives

$$-b \sum x^2 + (1 - b^2) \sum xy + b \sum y^2 + \tfrac{1}{n}(b^2 - 1) \times \left(\sum y - b \sum x\right) \sum x - \frac{2}{n}\left(\sum y - b \sum x\right) b \sum y + \frac{1}{n} b\left(\sum y - b \sum x\right)^2 = 0 \qquad (13)$$

After a fair bit of algebra, the result is

$$b^2 + \frac{\sum y^2 - \sum x^2 + \frac{1}{n}\left[\left(\sum x\right)^2 - \left(\sum y\right)^2\right]}{\frac{1}{n} \sum x \sum y - \sum xy} b - 1 = 0. \qquad (14)$$

So define

$$B \equiv \frac{1}{2} \frac{\left[\sum y^2 - \frac{1}{n}\left(\sum y\right)^2\right] - \left[\sum x^2 - \frac{1}{n}\left(\sum x\right)^2\right]}{\frac{1}{n} \sum x \sum y - \sum xy} = \frac{1}{2} \frac{\left(\sum y^2 - n\bar{y}^2\right) - \left(\sum x^2 - n\bar{x}^2\right)}{n\bar{x}\bar{y} - \sum xy}, \qquad (15)$$

and the QUADRATIC FORMULA gives

$$b = -B \pm \sqrt{B^2 + 1}, \qquad (16)$$

with a found using (7). Note the rather unwieldy form of the best-fit parameters in the formulation. In addition, minimizing $R_\perp^2$ for a second- or higher-order POLYNOMIAL leads to polynomial equations having *higher* order, so this formulation cannot be extended.

Vertical least squares fitting proceeds by finding the sum of the *squares* of the *vertical* deviations R^2 of a set of n data points

$$R^2 \equiv \sum [y_i - f(x_i, a_1, a_2, \ldots, a_n)]^2 \qquad (17)$$

from a function f. Note that this procedure does *not* minimize the actual deviations from the line (which would be measured perpendicular to the given function). In addition, although the *unsquared* sum of distances might seem a more appropriate quantity to minimize, use of the absolute value results in discontinuous derivatives which cannot be treated analytically. The square deviations from each point are therefore summed, and the resulting residual is then minimized to find the best fit line. This procedure

results in outlying points being given disproportionately large weighting.

The condition for R^2 to be a minimum is that

$$\frac{\partial(R^2)}{\partial a_i}=0 \tag{18}$$

for $i=1, ..., n$. For a linear fit,

$$f(a,\ b)=a+bx, \tag{19}$$

so

$$R^2(a,\ b)\equiv\sum_{i=1}^{n}[y_i-(a+bx_i)]^2 \tag{20}$$

$$\frac{\partial(R^2)}{\partial a}=-2\sum_{i=1}^{n}[y_i-(a+bx_i)]=0 \tag{21}$$

$$\frac{\partial(R^2)}{\partial b}=-2\sum_{i=1}^{n}[y_i-(a+bx_i)]x_i=0. \tag{22}$$

These lead to the equations

$$na+b\sum x=\sum y \tag{23}$$

$$a\sum x+b\sum x^2=\sum xy, \tag{24}$$

where the subscripts have been dropped for conciseness. In MATRIX form,

$$\begin{bmatrix} n & \sum x \\ \sum x & \sum x^2 \end{bmatrix}\begin{bmatrix} a \\ b \end{bmatrix}=\begin{bmatrix} \sum y \\ \sum xy \end{bmatrix}, \tag{25}$$

so

$$\begin{bmatrix} a \\ b \end{bmatrix}=\begin{bmatrix} n & \sum x \\ \sum x & \sum x^2 \end{bmatrix}^{-1}\begin{bmatrix} \sum y \\ \sum xy \end{bmatrix}. \tag{26}$$

The 2×2 MATRIX INVERSE is

$$\begin{bmatrix} a \\ b \end{bmatrix}=\frac{1}{n\sum x^2-\left(\sum x\right)^2}\times\begin{bmatrix} \sum y\sum x^2-\sum x\sum xy \\ n\sum xy-\sum x\sum y \end{bmatrix}, \tag{27}$$

so

$$a=\frac{\sum y\sum x^2-\sum x\sum xy}{n\sum x^2-\left(\sum x\right)^2} \tag{28}$$

$$=\frac{\bar{y}\sum x^2-\bar{x}\sum xy}{\sum x^2-n\bar{x}^2} \tag{29}$$

$$b=\frac{n\sum xy-\sum x\sum y}{n\sum x^2-\left(\sum x\right)^2} \tag{30}$$

$$=\frac{\sum xy-n\bar{x}\bar{y}}{\sum x^2-n\bar{x}^2} \tag{31}$$

(Kenney and Keeping 1962). These can be rewritten in a simpler form by defining the sums of squares

$$\mathrm{ss}_{xx}=\sum_{i=1}^{n}(x_i-\bar{x})^2=\left(\sum x^2\right)-n\bar{x}^2 \tag{32}$$

$$\mathrm{ss}_{yy}=\sum_{i=1}^{n}(y_i-\bar{y})^2=\left(\sum y^2\right)-n\bar{y}^2 \tag{33}$$

$$\mathrm{ss}_{xy}=\sum_{i=1}^{n}(x_i-\bar{x})(y_i-\bar{y})=\left(\sum xy\right)-n\bar{x}\bar{y}, \tag{34}$$

which are also written as

$$\sigma_x^2=\mathrm{ss}_{xx} \tag{35}$$

$$\sigma_y^2=\mathrm{ss}_{yy} \tag{36}$$

$$\mathrm{cov}(x,\ y)=\mathrm{ss}_{xy}. \tag{37}$$

Here, $\mathrm{cov}(x,\ y)$ is the COVARIANCE and σ_x^2 and σ_y^2 are variances. Note that the quantities $\Sigma\, xy$ and $\Sigma\, x^2$ can also be interpreted as the DOT PRODUCTS

$$\sum x^2=\mathbf{x}\cdot\mathbf{x} \tag{38}$$

$$\sum xy=\mathbf{x}\cdot\mathbf{y}. \tag{39}$$

In terms of the sums of squares, the REGRESSION COEFFICIENT b is given by

$$b=\frac{\mathrm{cov}(x,\ y)}{\sigma_x^2}=\frac{\mathrm{ss}_{xy}}{\mathrm{ss}_{xx}}, \tag{40}$$

and a is given in terms of b using (24) as

$$a=\bar{y}-b\bar{x}. \tag{41}$$

The overall quality of the fit is then parameterized in terms of a quantity known as the CORRELATION COEFFICIENT, defined by

$$r^2=\frac{\mathrm{ss}_{xy}^2}{\mathrm{ss}_{xx}\mathrm{ss}_{yy}}, \tag{42}$$

which gives the proportion of ss_{yy} which is accounted for by the regression.

The STANDARD ERRORS for a and b are

$$\mathrm{SE}(a)=s\sqrt{\frac{1}{n}+\frac{\bar{x}^2}{\mathrm{ss}_{xx}}} \tag{43}$$

$$\mathrm{SE}(b)=\frac{s}{\sqrt{\mathrm{ss}_{xx}}}. \tag{44}$$

Let $\hat{y}_i$ be the vertical coordinate of the best-fit line with x-coordinate x_i, so

$$\hat{y}_i\equiv a+bx_i, \tag{45}$$

then the error between the actual vertical point y_i and the fitted point is given by

$$e_i \equiv y_i - \hat{y}_i. \quad (46)$$

Now define s^2 as an estimator for the variance in e_i,

$$s^2 = \sum_{i=1}^{n} \frac{e_i^2}{n-2}. \quad (47)$$

Then s can be given by

$$s = \sqrt{\frac{\text{ss}_{yy} - b\,\text{ss}_{xy}}{n-2}} = \sqrt{\frac{\text{ss}_{yy} - \frac{\text{ss}_{xy}^2}{\text{ss}_{xx}}}{n-2}} \quad (48)$$

(Acton 1966, pp. 32–5; Gonick and Smith 1993, pp. 202–04).

Generalizing from a straight line (i.e., first degree polynomial) to a kth degree POLYNOMIAL

$$y = a_0 + a_1 x + \ldots + a_k x^k, \quad (49)$$

the residual is given by

$$R^2 \equiv \sum_{i=1}^{n} [y_i - (a_0 + a_1 x_i + \ldots + a_k x_i^k)]^2. \quad (50)$$

The PARTIAL DERIVATIVES (again dropping superscripts) are

$$\frac{\partial(R^2)}{\partial a_0} = -2 \sum [y - (a_0 + a_1 x + \ldots + a_k x^k)] = 0 \quad (51)$$

$$\frac{\partial(R^2)}{\partial a_1} = -2 \sum [y - (a_0 + a_1 x + \ldots + a_k x^k)]x = 0 \quad (52)$$

$$\frac{\partial(R^2)}{\partial a_k} = -2 \sum [y - (a_0 + a_1 x + \ldots + a_k x^k)]x^k = 0. \quad (53)$$

These lead to the equations

$$a_0 n + a_1 \sum x + \ldots + a_k \sum x^k = \sum y \quad (54)$$

$$a_0 \sum x + a_1 \sum x^2 + \ldots + a_k \sum x^{k+1} = \sum xy \quad (55)$$

$$a_0 \sum x^k + a_1 \sum x^{k+1} + \ldots + a_k \sum x^{2k} = \sum x^k y \quad (56)$$

or, in MATRIX form

$$\begin{bmatrix} n & \sum x & \cdots & \sum x^k \\ \sum x & \sum x^2 & \cdots & \sum x^{k+1} \\ \vdots & \vdots & \ddots & \vdots \\ \sum x^k & \sum x^{k+1} & \cdots & \sum x^{2k} \end{bmatrix} \begin{bmatrix} a_0 \\ a_1 \\ \vdots \\ a_k \end{bmatrix} = \begin{bmatrix} \sum y \\ \sum xy \\ \vdots \\ \sum x^k y \end{bmatrix}. \quad (57)$$

This is a VANDERMONDE MATRIX. We can also obtain the MATRIX for a least squares fit by writing

$$\begin{bmatrix} 1 & x_1 & \cdots & x_1^k \\ 1 & x_2 & \cdots & x_2^k \\ \vdots & \vdots & \ddots & \vdots \\ 1 & x_n & \cdots & x_n^k \end{bmatrix} \begin{bmatrix} a_0 \\ a_1 \\ \vdots \\ a_k \end{bmatrix} = \begin{bmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{bmatrix}. \quad (58)$$

Premultiplying both sides by the TRANSPOSE of the first MATRIX then gives

$$\begin{bmatrix} 1 & 1 & \cdots & 1 \\ x_1 & x_2 & \cdots & x_n \\ \vdots & \vdots & \ddots & \vdots \\ x_1^k & x_2^k & \cdots & x_n^k \end{bmatrix} \begin{bmatrix} 1 & x_1 & \cdots & x_1^k \\ 1 & x_2 & \cdots & x_2^k \\ \vdots & \vdots & \ddots & \vdots \\ 1 & x_n & \cdots & x_n^k \end{bmatrix} \begin{bmatrix} a_0 \\ a_1 \\ \vdots \\ a_k \end{bmatrix} = \begin{bmatrix} 1 & 1 & \cdots & 1 \\ x_1 & x_2 & \cdots & x_n \\ \vdots & \vdots & \ddots & \vdots \\ x_1^k & x_2^k & \cdots & x_n^k \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{bmatrix}, \quad (59)$$

so

$$\begin{bmatrix} n & \sum x & \cdots & \sum x^n \\ \sum x & \sum x^2 & \cdots & \sum x^{n+1} \\ \vdots & \vdots & \ddots & \vdots \\ \sum x^n & \sum x^{n+1} & \cdots & \sum x^{2n} \end{bmatrix} \begin{bmatrix} a_0 \\ a_1 \\ \vdots \\ a_k \end{bmatrix} = \begin{bmatrix} \sum y \\ \sum xy \\ \vdots \\ \sum x^k y \end{bmatrix}. \quad (60)$$

As before, given m points (x_i, y_i) and fitting with POLYNOMIAL COEFFICIENTS a_0, ..., a_n gives

$$\begin{bmatrix} y_1 \\ y_2 \\ \vdots \\ y_m \end{bmatrix} = \begin{bmatrix} 1 & x_1 & x_1^2 & \cdots & x_1^n \\ 1 & x_2 & x_2^2 & \cdots & x_2^n \\ \vdots & \vdots & \ddots & & \vdots \\ 1 & x_m & x_m^2 & \cdots & x_m^n \end{bmatrix} \begin{bmatrix} a_0 \\ a_1 \\ \vdots \\ a_n \end{bmatrix}, \quad (61)$$

In MATRIX notation, the equation for a polynomial fit is given by

$$\mathbf{y} = \mathsf{X}\mathbf{a}. \quad (62)$$

This can be solved by premultiplying by the MATRIX TRANSPOSE X^T,

$$\mathsf{X}^\mathrm{T}\mathbf{y} = \mathsf{X}^\mathrm{T}\mathsf{X}\mathbf{a}. \quad (63)$$

This MATRIX EQUATION can be solved numerically, or can be inverted directly if it is well formed, to yield the solution vector

$$\mathbf{a} = (\mathsf{X}^\mathrm{T}\mathsf{X})^{-1}\mathsf{X}^\mathrm{T}\mathbf{y}. \quad (64)$$

Setting $m = 1$ in the above equations reproduces the linear solution.

Least Squares Fitting—Exponential

To fit a functional form

$$y = Ae^{Bx}, \tag{1}$$

take the LOGARITHM of both sides

$$\ln y = \ln A + Bx. \tag{2}$$

The best-fit values are then

$$a = \frac{\sum \ln y \sum x^2 - \sum x \sum x \ln y}{n \sum x^2 - \left(\sum x\right)^2} \tag{3}$$

$$b = \frac{n \sum x \ln y - \sum x \sum \ln y}{n \sum x^2 - \left(\sum x\right)^2}, \tag{4}$$

where $B \equiv b$ and $A \equiv \exp(a)$.

This fit gives greater weights to small y values so, in order to weight the points equally, it is often better to minimize the function

$$\sum y(\ln y - a - bx)^2. \tag{5}$$

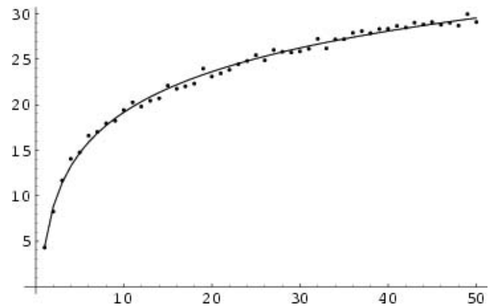
Applying LEAST SQUARES FITTING gives

$$a \sum y + b \sum xy = \sum y \ln y \tag{6}$$

$$a \sum xy + b \sum x^2 y = \sum xy \ln y \tag{7}$$

$$\begin{bmatrix} \sum y & \sum xy \\ \sum xy & \sum x^2 y \end{bmatrix} \begin{bmatrix} a \\ b \end{bmatrix} = \begin{bmatrix} \sum y \ln y \\ \sum xy \ln y \end{bmatrix}. \tag{8}$$

Solving for a and b,



$$a = \frac{\sum(x^2 y) \sum(y \ln y) - \sum(xy) \sum(xy \ln y)}{\sum y \sum(x^2 y) - \left(\sum xy\right)^2} \tag{9}$$

$$b = \frac{\sum y \sum(xy \ln y) - \sum(xy) \sum(y \ln y)}{\sum y \sum(x^2 y) - \left(\sum xy\right)^2}. \tag{10}$$

In the plot above, the short-dashed curve is the fit computed from (3) and (4) and the long-dashed curve is the fit computed from (9) and (10).

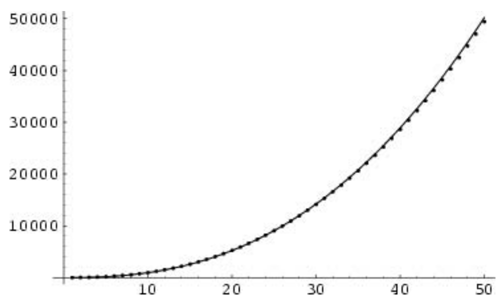
Least Squares Fitting—Logarithmic

Given a function OF THE FORM

$$y = a + b \ln x, \tag{1}$$

the COEFFICIENTS can be found from LEAST SQUARES



FITTING as

$$b = \frac{n \sum(y \ln x) - \sum y \sum(\ln x)}{n \sum\left[(\ln x)^2\right] - \left[\sum(\ln x)\right)^2} \tag{2}$$

$$a = \frac{\sum y - b \sum(\ln x)}{n}. \tag{3}$$

See also LEAST SQUARES FITTING, LEAST SQUARES FITTING–EXPONENTIAL, LEAST SQUARES FITTING–POWER LAW

Least Squares Fitting—Power Law

Given a function OF THE FORM

$$y = Ax^B, \tag{1}$$

LEAST SQUARES FITTING gives the COEFFICIENTS as

$$b = \frac{n \sum(\ln x \ln y) - \sum(\ln x)\sum(\ln y)}{n \sum[(\ln x)^2] - (\sum \ln x)^2} \tag{2}$$

$$a = \frac{\sum(\ln y) - b \sum(\ln x)}{n}, \tag{3}$$

where $B \equiv b$ and $A \equiv \exp(a)$.

CARMICHAEL FUNCTION

Least Upper Bound

SUPREMUM

Lebesgue Constants (Fourier Series)

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Assume a function f is integrable over the interval $[-\pi, \pi]$ and $S_n(f, x)$ is the nth partial sum of the FOURIER SERIES of f, so that

$$a_k = \frac{1}{\pi}\int_{-\pi}^{\pi} f(t)\cos(kt)\,dt \tag{1}$$

$$b_k = \frac{1}{\pi}\int_{-\pi}^{\pi} f(t)\sin(kt)\,dt \tag{2}$$

and

$$S_n(f, x) = \tfrac{1}{2} a_0 + \left\{\sum_{k=1}^{n}[a_k \cos(kx) + b_k \sin(kx)]\right\}. \tag{3}$$

If

$$|f(x)| \leq 1 \tag{4}$$

for all x, then

$$S_n(f, x) \leq \frac{1}{\pi}\int_0^{\pi} \frac{\left|\sin\left[\frac{1}{2}(2n+1)\theta\right]\right|}{\sin\left(\frac{1}{2}\theta\right)}\,d\theta = L_n, \tag{5}$$

and L_n is the smallest possible constant for which this holds for all continuous f. The first few values of L_n are

$$L_0 = 1 \tag{6}$$

$$L_1 = \frac{1}{3} + \frac{2\sqrt{3}}{\pi} = 1.435991124\ldots \tag{7}$$

$$L_2 = \frac{1}{5} + \frac{\sqrt{25 - 2\sqrt{5}}}{\pi} = 1.642188435\ldots \tag{8}$$

$$\begin{aligned} L_3 = {} & \frac{1}{7} + \frac{1}{\pi}\left[4 \sin\left(\tfrac{2}{7}\pi\right) - 2 \sin\left(\tfrac{4}{7}\pi\right) + \tfrac{16}{3}\sin\left(\tfrac{6}{7}\pi\right)\right. \\ & \left. -2 \sin\left(\tfrac{8}{7}\pi\right) + \tfrac{2}{3}\sin\left(\tfrac{12}{7}\pi\right) + \tfrac{4}{3}\sin\left(\tfrac{18}{7}\pi\right)\right] \\ & = 1.778322861\ldots. \end{aligned} \tag{9}$$

$$\begin{aligned} L_4 = {} & \frac{39\sqrt{3}}{18\pi} + \frac{1}{9} + \frac{1}{pi}\left[+4 \sin\left(\tfrac{2}{9}\pi\right) + 2 \sin\left(\tfrac{4}{9}\pi\right)\right. \\ & \left. +5 \sin\left(\tfrac{8}{9}\pi\right) + 3 \sin\left(\tfrac{16}{9}\pi\right) + \sin\left(\tfrac{32}{9}\pi\right)\right] \\ & = 1.880080599\ldots. \end{aligned} \tag{10}$$

Some sum FORMULAS for L_n include

$$\begin{aligned} L_n & = \frac{1}{2n+1} + \frac{2}{\pi}\sum_{k=1}^{n}\frac{1}{k}\tan\left(\frac{\pi k}{2n+1}\right) \\ & = \frac{16}{\pi^2}\sum_{k=1}^{\infty}\sum_{j=1}^{(2n+1)k}\frac{1}{4k^2-1}\,\frac{1}{2j-1} \end{aligned} \tag{11}$$

(Zygmund 1959) and integral FORMULAS include

$$L_n = 4\int_0^{\infty}\frac{\tanh[(2n+1)x]}{\tanh x}\,\frac{dx}{\pi^2 + 4x^2}$$

$$= \frac{4}{\pi^2} \int_0^\infty \frac{\sinh[(2n+1)x]}{\sinh x} \ln\left\{\coth\left[\tfrac{1}{2}(2n+1)x\right]\right\} dx \tag{12}$$

(Hardy 1942). For large n,

$$\frac{4}{\pi^2} \ln n < L_n < 3 + \frac{4}{\pi^2} \ln n. \tag{13}$$

This result can be generalized for an r-differentiable function satisfying

$$\left|\frac{d^r f}{dx^r}\right| \leq 1 \tag{14}$$

for all x. In this case,

$$|f(x) - S_n(f, x)| \leq L_{n,r} = \frac{4}{\pi^2} \frac{\ln n}{n^r} + \mathcal{O}\left(\frac{1}{n^r}\right), \tag{15}$$

where

$$L_{n,r} = \begin{cases} \frac{1}{\pi} \int_{-\pi}^{\pi} \left| \sum_{k=n+1}^{\infty} \frac{\sin(kx)}{k^r} \right| dx & \text{for } r \geq 1 \text{ odd} \\ \frac{1}{\pi} \int_{-\pi}^{\pi} \left| \sum_{k=n+1}^{\infty} \frac{\cos(kx)}{k^r} \right| dx & \text{for } r \geq 1 \text{ even} \end{cases} \tag{16}$$

(Kolmogorov 1935, Zygmund 1959).

Watson (1930) showed that

$$\lim_{n\to\infty} \left[L_n - \frac{4}{\pi^2} \ln(2n+1)\right] = c, \tag{17}$$

where

$$c = \frac{8}{\pi^2} \left(\sum_{k=1}^{\infty} \frac{\ln k}{4k^2 - 1}\right) - \frac{4}{\pi^2} \frac{\Gamma'\left(\frac{1}{2}\right)}{\Gamma\left(\frac{1}{2}\right)} \tag{18}$$

$$= \frac{8}{\pi^2} \left[\sum_{j=0}^{\infty} \frac{\lambda(2j+2) - 1}{2j+1}\right] + \frac{4}{\pi^2}(2 \ln 2 + \gamma) \tag{19}$$

$$= 0.9894312738..., \tag{20}$$

where $\Gamma(z)$ is the GAMMA FUNCTION, $\lambda(z)$ is the DIRICHLET LAMBDA FUNCTION, and γ is the EULER-MASCHERONI CONSTANT.

Lebesgue Constants (Lagrange Interpolation)

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Define the nth Lebesgue constant for the LAGRANGE INTERPOLATING POLYNOMIAL by

$$\Lambda_n(X) \equiv \max_{-1 \leq x \leq 1} \sum_{k=1}^{n} \left| \prod_{j \neq k} \frac{x - x_j}{x_k - x_j} \right|. \tag{1}$$

It is true that

$$\Lambda_n > \frac{4}{\pi^2} \ln n - 1. \tag{2}$$

The efficiency of a Lagrange interpolation is related to the rate at which Λ_n increases. Erdos (1961) proved that there exists a POSITIVE constant such that

$$\Lambda_n > \frac{2}{\pi} \ln n - C \tag{3}$$

for all n. Erdos (1961) further showed that

$$\Lambda_n < \frac{2}{\pi} \ln n + 4, \tag{4}$$

so (3) cannot be improved upon.

Lebesgue Covering Dimension

An important DIMENSION and one of the first dimensions investigated. It is defined in terms of covering sets, and is therefore also called the COVERING DIMENSION. Another name for the Lebesgue covering dimension is the TOPOLOGICAL DIMENSION.

A SPACE has Lebesgue covering dimension m if for every open COVER of that space, there is an open COVER that refines it such that the refinement has order at most $m+1$. Consider how many elements of the cover contain a given point in a base space. If this has a maximum over all the points in the base space, then this maximum is called the order of the cover. If a SPACE does not have Lebesgue covering dimension m for any m, it is said to be infinite dimensional.

Results of this definition are:

1. Two homeomorphic spaces have the same dimension,
2. $\mathbb{R}^n$ has dimension n,
3. A TOPOLOGICAL SPACE can be embedded as a closed subspace of a EUCLIDEAN SPACE IFF it is LOCALLY COMPACT, HAUSDORFF, SECOND COUNTA-

BLE, and is finite-dimensional (in the sense of the LEBESGUE DIMENSION), and

4. Every compact metrizable m-dimensional TOPOLOGICAL SPACE can be embedded in $\mathbb{R}^{2m+1}$.

Lebesgue Decomposition (Measure)

Any COMPLEX MEASURE λ decomposes into an ABSOLUTELY CONTINUOUS measure λ_a and a SINGULAR MEASURE λ_c, with respect to some positive measure μ. This is the LEBESGUE DECOMPOSITION

$$\lambda = \lambda_a + \lambda_c.$$

See also ABSOLUTELY CONTINUOUS, COMPLEX MEASURE, FUNDAMENTAL THEOREMS OF CALCULUS, LEBESGUE MEASURE, POLAR REPRESENTATION (MEASURE), RADON-NIKODYM THEOREM, SINGULAR MEASURE

Lebesgue Integrable

A real-valued function f defined on the reals $\mathbb{R}$ is called Lebesgue integrable if there exists a SEQUENCE of STEP FUNCTIONS $\{f_n\}$ such that the following two conditions are satisfied:

1. $\Sigma_{n=1}^{\infty} \int |f_n| < \infty$,
2. $f(x) = \Sigma_{n=1}^{\infty} f_n(x)$ for every $x \in \mathbb{R}$ such that $\Sigma_{n=1}^{\infty} \int |f_n| < \infty$.

Here, the above integral denotes the ordinary RIEMANN INTEGRAL. Note that this definition avoids explicit use of the LEBESGUE MEASURE.

See also INTEGRAL, LEBESGUE INTEGRAL, RIEMANN INTEGRAL, STEP FUNCTION

Lebesgue Integral

The LEBESGUE INTEGRAL is defined in terms of upper and lower bounds using the LEBESGUE MEASURE of a SET. It uses a LEBESGUE SUM $S_n = \eta_i \mu(E_i)$ where η_i is the value of the function in subinterval i, and $\mu(E_i)$ is the LEBESGUE MEASURE of the SET E_i of points for which values are approximately η_i. This type of integral covers a wider class of functions than does the RIEMANN INTEGRAL.

The Lebesgue integral of a function f over a MEASURE SPACE X is written

$$\int_X f,$$

or sometimes

$$\int_X f \, d\mu$$

to emphasize that the integral is taken with respect to the MEASURE μ.

Lebesgue Measurability Problem

A problem related to the CONTINUUM HYPOTHESIS which was solved by Solovay (1970) using the INACCESSIBLE CARDINALS AXIOM. It has been proven by Shelah and Woodin (1990) that use of this AXIOM is essential to the proof.

See also CONTINUUM HYPOTHESIS, INACCESSIBLE CARDINALS AXIOM, LEBESGUE MEASURE

Lebesgue Measure

An extension of the classical notions of length and AREA to more complicated sets. Given an open set $S \equiv \Sigma_k(a_k,\ b_k)$ containing DISJOINT intervals,

$$\mu_L(S) \equiv \sum_k (b_k - a_k).$$

Given a CLOSED SET $S' \equiv [a,\ b] - \Sigma_k(a_k,\ b_k)$,

$$\mu_L(S') \equiv (b-a) - \sum_k (b_k - a_k).$$

A unit LINE SEGMENT has Lebesgue measure 1; the CANTOR SET has Lebesgue measure 0. The MINKOWSKI MEASURE of a bounded, CLOSED SET is the same as its Lebesgue measure (Ko 1995).

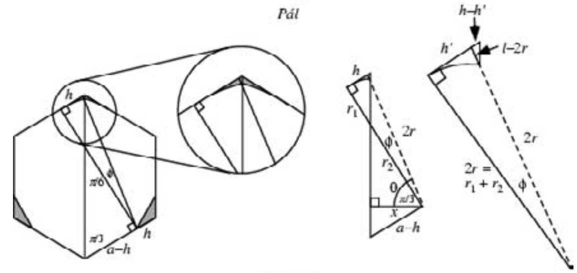
Lebesgue Minimal Problem



Pál Sprague

Find the plane LAMINA of least AREA A which is capable of covering any plane figure of unit GENERALIZED DIAMETER. A UNIT CIRCLE is too small, but a HEXAGON circumscribed on the UNIT CIRCLE is larger than necessary. Pál (1920) showed that the hexagon can be reduced by cutting off two EQUILATERAL TRIANGLES on the corners of the hexagon which are tangent to the hexagon's INCIRCLE (Wells 1991; left figure above). Sprague subsequently demonstrated that an additional small curvilinear region could be removed (Wells 1991; right figure above). These constructions give upper bounds.

Pál

Sprague

The HEXAGON having INRADIUS $r = 1/2$ (giving a DIAMETER of 1) has side length

$$a = 2r \tan\left(\frac{\pi}{n}\right) = \tfrac{1}{3}\sqrt{3}, \tag{1}$$

and the area of this HEXAGON is

$$A_1 = nr^2 \tan\left(\frac{\pi}{n}\right) = \tfrac{1}{2}\sqrt{3} \approx 0.866025. \tag{2}$$

In the above figure, the SAGITTA is given by

$$s = r \tan\left(\frac{\pi}{n}\right)\tan\left(\frac{\pi}{2n}\right) = \tfrac{1}{6}\left(2\sqrt{3}-3\right), \tag{3}$$

and the other distances by

$$b = s \tan\left(\frac{\pi}{3}\right) = \sqrt{3}s \tag{4}$$

$$h = \sqrt{s^2+b^2} = 2s, \tag{5}$$

so the area of one of the equilateral triangles removed in Pál's reduction is

$$A_\Delta = bs = \sqrt{3}s^2 = \tfrac{1}{12}\left(7\sqrt{3} = 12\right) \approx 0.0773505, \tag{6}$$

so the area left after removing two of these triangles is

$$A_2 \equiv A_1 - 2A_\Delta = \tfrac{2}{3}\left(3-\sqrt{3}\right) \approx 0.845299. \tag{7}$$

Computing the area of the region removed in Sprague's construction is more involved. First, use similar triangles

$$\frac{a-h}{h} = \frac{r_2}{r_1} \tag{8}$$

together with $r_1+r_2=r$ to obtain

$$r_2=\frac{2r(a-h)}{a}=\sqrt{3}-1. \tag{9}$$

Then

$$x=r_2\cos\left(\frac{\pi}{3}\right)=\tfrac{1}{2}\left(\sqrt{3}-1\right), \tag{10}$$

and the angle θ is given by

$$\theta=\cos^{-1}\left(\frac{x}{2r}\right)=\cos^{-1}\left[\tfrac{1}{2}\left(\sqrt{3}-1\right)\right], \tag{11}$$

and the angle ϕ is just

$$\phi=\theta-\tfrac{1}{3}\pi. \tag{12}$$

The distance h' is

$$h'=2r\tan\phi \tag{13}$$

$$l=2r\sec\phi, \tag{14}$$

and the area between the triangle and sector is

$$dA_3^{(1)}=rh-\tfrac{1}{2}(2r)^2\phi=2r^2(\tan\phi-\phi)=\tfrac{1}{2}(\tan\phi-\phi)$$
$$\approx 0.000554738. \tag{15}$$

The area of the small triangle is

$$dA_3^{(2)}=\tfrac{1}{2}(l-2r)(h-h')$$
$$=\tfrac{1}{6}(\sec\phi-1)(2\sqrt{3}-3-3\tan\phi)$$
$$\approx 0.0000264307, \tag{16}$$

so the total area remaining is

$$A_3=A_2-2(dA_3^{(1)}-dA_3^{(2)})=0.844137. \tag{17}$$

It is also known that a lower bound for the AREA is given by

$$A>\tfrac{1}{8}\pi+\tfrac{1}{4}\sqrt{3}\approx 0.825712 \tag{18}$$

(Ogilvy 1990).

Lebesgue-Radon Integral

LEBESGUE-STIELTJES INTEGRAL

Lebesgue's Dominated Convergence Theorem

Suppose that $\{f_n\}$ is a sequence of MEASURABLE FUNCTIONS, that $f_n\to f$, as $n\to\infty$, and that $|f_n|\leq g$ for all n, where g is integrable. Then f is integrable, and

$$\int f\,d\mu=\lim_{n\to\infty}\int f_n\,d\mu.$$

Leech Lattice

A 24-D Euclidean lattice. An AUTOMORPHISM of the Leech lattice modulo a center of two leads to the CONWAY GROUP Co_1. Stabilization of the 1- and 2-D sublattices leads to the CONWAY GROUPS Co_2 and Co_3, the HIGMAN-SIMS GROUP HS and the MCLAUGHLIN GROUP McL.

The Leech lattice appears to be the densest HYPERSPHERE PACKING in 24-D, and results in each HYPERSPHERE touching 195,560 others. The number of vectors with norm n in the Leech lattice (i.e., its "theta series"rpar; is given by

$$\theta(n) = \tfrac{65520}{691}[\sigma_{11}(n) - \tau(n)], \tag{1}$$

where σ_{11} is the DIVISOR FUNCTION giving the sum of the 11th powers of the DIVISORS of n and $\tau(n)$ is the TAU FUNCTION (Conway and Sloane 1993, p. 135). The first few values for n = 1, 2, ... are 0, 196560, 16773120, 398034000, ... (Sloane's A008408). This is an immediate consequence of the theta function for Leech's lattice being a weight 12 MODULAR FORM and having no vectors of norm two. $\theta(n)$ has the generating function

$$f(q) = [E_2(q)]^3 - 720q^2 \prod_{m=1}^{\infty}(1-q^{2m})^{24} \tag{2}$$

$$= \left(1 + 240 \sum_{m=1}^{\infty} \sigma_3(m) q^{2m}\right)^3 - 720q^2 \prod_{m=1}^{\infty}(1-q^{2m})^{24} \tag{3}$$

$$1 + 196560q^4 + 16773120q^6 + 3980034000q^8 + \ldots, \tag{4}$$

where $E_2(q)$ is the RAMANUJAN-EISENSTEIN SERIES which is the theta series of the E_8 lattice (Sloane's A004009).

Legendre Addition Theorem

SPHERICAL HARMONIC ADDITION THEOREM

Legendre Differential Equation

The second-order ORDINARY DIFFERENTIAL EQUATION

$$(1-x^2)\frac{d^2y}{dx^2} - 2x\frac{dy}{dx} + l(l+1)y = 0, \tag{1}$$

which can be rewritten

$$\frac{d}{dx}\left[(1-x^2)\frac{dy}{dx}\right] + l(l+1)y = 0. \tag{2}$$

The above form is a special case of the associated Legendre differential equation with $m = 0$. The Legendre differential equation has REGULAR SINGULAR POINTS at -1, 1, and ∞.

If the variable x is replaced by $\cos\theta$, then the Legendre differential equation becomes

$$\frac{d^2y}{d\theta^2} + \frac{\cos\theta}{\sin\theta}\frac{dy}{d\theta} + l(l+1)y = 0, \tag{3}$$

as is derived below for the associated Legendre differential equation with $m = 0$.

Since the Legendre differential equation is a second-order ORDINARY DIFFERENTIAL EQUATION, it has two linearly independent solutions. A solution $P_l(x)$ which is regular at the origin is called a LEGENDRE FUNCTION OF THE FIRST KIND, while a solution $Q_l(x)$ which is singular at the origin is called a LEGENDRE FUNCTION OF THE SECOND KIND. If l is an integer, the function of the first kind reduces to a polynomial known as the LEGENDRE POLYNOMIAL.

The Legendre differential equation can be solved using the standard method of making a series expansion,

$$y = \sum_{n=0}^{\infty} a_n x^n \tag{4}$$

$$y' = \sum_{n=0}^{\infty} n a_n x^{n-1} \tag{5}$$

$$y'' = \sum_{n=0}^{\infty} n(n-1) a_n x^{n-2}. \tag{6}$$

Plugging in,

$$(1-x^2)\sum_{n=0}^{\infty} n(n-1)a_n x^{n-2} - 2x\sum_{n=0}^{\infty} n a_n x^{n-1} + l(l+1)\sum_{n=0}^{\infty} a_n x^n = 0 \tag{7}$$

$$\sum_{n=0}^{\infty} n(n-1)a_n x^{n-2} - \sum_{n=0}^{\infty} n(n-1)a_n x^n$$

$$-2x\sum_{n=0}^{\infty} na_n x^{n-1} + l(l+1)\sum_{n=0}^{\infty} a_n x^n = 0 \quad (8)$$

$$\sum_{n=0}^{\infty} n(n-1)a_n x^{n-2} - \sum_{n=0}^{\infty} n(n-1)a_n x^n$$

$$-2\sum_{n=0}^{\infty} na_n x^n + l(l+1)\sum_{n=0}^{\infty} a_n x^n = 0 \quad (9)$$

$$\sum_{n=0}^{\infty} (n+2)(n+1)a_{n+2}x^n - \sum_{n=0}^{\infty} n(n-1)a_n x^n$$

$$-2\sum_{n=0}^{\infty} na_n x^n + l(l+1)\sum_{n=0}^{\infty} a_n x^n = 0 \quad (10)$$

$$\sum_{n=0}^{\infty}\{(n+1)(n+2)a_{n+2} + [-n(n-1)$$

$$-2n + l(l+1)]a_n\} = 0, \quad (11)$$

so each term must vanish and

$$(n+1)(n+2)a_{n+2} + [-n(n+1) + l(l+1)]a_n = 0 \quad (12)$$

$$a_{n+2} = \frac{n(n+1) - l(l+1)}{(n+1)(n+2)} a_n$$

$$= -\frac{[l+(n+1)](l-n)}{(n+1)(n+2)} a_n. \quad (13)$$

Therefore,

$$a_2 = -\frac{l(l+1)}{1 \cdot 2} a_0 \quad (14)$$

$$a_4 = -\frac{(l-2)(l+3)}{3 \cdot 4} a_2$$

$$= (-1)^2 \frac{[(l-2)l][(l+1)(l+3)]}{1 \cdot 2 \cdot 3 \cdot 4} a_0 \quad (15)$$

$$a_6 = -\frac{(l-4)(l+5)}{5 \cdot 6} a_4$$

$$= (-1)^3 \frac{[(l-4)(l-2)l][(l+1)(l+3)(l+5)]}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5 \cdot 6} a_0, \quad (16)$$

so the EVEN solution is

$$y_1(x) = 1 + \sum_{n=1}^{\infty}(-1)^n$$

$$\times \frac{[(l-2n+2)\ldots(l-2)l][(l+1)(l+3)\ldots(l+2n-1)]}{(2n)!} x^{2n}. \quad (17)$$

Similarly, the ODD solution is

$$y_2(x) = x + \sum_{n=1}^{\infty}(-1)^n$$

$$\times \frac{[(l-2n+1)\cdots(l-3)(l-1)][(l+2)(l+4)\cdots(l+2n)]}{(2n+1)!} x^{2m+1}. \quad (18)$$

If l is an EVEN INTEGER, the series $y_1(x)$ reduces to a POLYNOMIAL of degree l with only EVEN POWERS of x and the series $y_2(x)$ diverges. If l is an ODD INTEGER, the series $y_2(x)$ reduces to a POLYNOMIAL of degree l with only ODD POWERS of x and the series $y_1(x)$ diverges. The general solution for an INTEGER l is then given by the LEGENDRE POLYNOMIALS

$$P_n(x) = c_n \begin{cases} y_1(x) & \text{for } l \text{ even} \\ y_2(x) & \text{for } l \text{ odd}, \end{cases} \quad (19)$$

where c_n is chosen so as to yield the normalization $P_n(1) = 1$.

The *associated* Legendre differential equation is

$$\frac{d}{dx}\left[(1-x^2)\frac{dy}{dx}\right] + \left[l(l+1) - \frac{m^2}{1-x^2}\right]y = 0, \quad (20)$$

which can be written

$$(1-x^2)\frac{d^2y}{dx} - 2x\frac{dy}{dx} + \left[l(l+1) - \frac{m^2}{1-x^2}\right]y = 0 \quad (21)$$

(Abramowitz and Stegun 1972; Zwillinger 1997, p. 124). The solutions $P_l^m(x)$ to this equation are called the associated Legendre polynomials (if l is an integer), or associated Legendre functions of the first kind (if l is not an integer). The complete solution is

$$y = C_1 P_l^m(x) + C_2 Q_l^m(x), \quad (22)$$

where $Q_l^m(x)$ is a LEGENDRE FUNCTION OF THE SECOND KIND.

The associated Legendre differential equation is often written in a form obtained by setting $x \equiv \cos\theta$. Using the identities

$$\frac{dy}{dx} = \frac{dy}{d(\cos\theta)} = -\frac{1}{\sin\theta}\frac{dy}{d\theta} \quad (23)$$

$$x\frac{dy}{dx} = -\frac{\cos\theta}{\sin\theta}\frac{dy}{d\theta}, \quad (24)$$

$$\frac{d^2y}{dx^2} = \frac{1}{\sin\theta}\frac{d}{d\theta}\left(\frac{1}{\sin\theta}\frac{dy}{d\theta}\right)$$

$$= \frac{1}{\sin\theta}\left(\frac{-\cos\theta}{\sin^2\theta}\right)\frac{dy}{d\theta} + \frac{1}{\sin^2\theta}\frac{d^2y}{d\theta^2}, \quad (25)$$

and

$$1 - x^2 = 1 - \cos^2\theta = \sin^2\theta, \quad (26)$$

therefore gives

$$(1-x^2)\frac{d^2y}{dx^2} = \sin^2\theta \frac{1}{\sin\theta}\left(\frac{-\cos\theta}{\sin^2\theta}\right)\frac{dy}{d\theta} + \frac{1}{\sin^2\theta}\frac{d^2y}{d\theta^2}$$

$$= \frac{d^2y}{d\theta^2} - \frac{\cos\theta}{\sin\theta}\frac{dy}{d\theta}. \qquad (27)$$

Plugging (23) into (27) and the result back into (21) gives

$$\left(\frac{d^2y}{d\theta^2} - \frac{\cos\theta}{\sin\theta}\frac{dy}{d\theta}\right) + 2\frac{\cos\theta}{\sin\theta}\frac{dy}{d\theta} + \left[l(l+1) - \frac{m^2}{\sin^2\theta}\right]y = 0 \qquad (28)$$

$$\frac{d^2y}{d\theta^2} + \frac{\cos\theta}{\sin\theta}\frac{dy}{d\theta} + \left[l(l+1) - \frac{m^2}{\sin^2\theta}\right]y = 0. \qquad (29)$$

Moon and Spencer (1961, p. 155) call

$$(1-x^2)y'' - 2xy' - \left[k^2a^2(x^2-1) - p(p+1) - \frac{q^2}{x^2-1}\right]y = 0 \qquad (30)$$

The Legendre wave function (Zwillinger 1997, p.124).

Legendre Duplication Formula

GAMMA FUNCTIONS of argument $2z$ can be expressed in terms of GAMMA FUNCTIONS of smaller arguments. From the definition of the BETA FUNCTION,

$$B(m, n) = \frac{\Gamma(m)\Gamma(n)}{\Gamma(m+n)} = \int_0^1 u^{m-1}(1-u)^{n-1}\,du. \qquad (1)$$

Now, let $m = n \equiv z$, then

$$\frac{\Gamma(z)\Gamma(z)}{\Gamma(2z)} = \int_0^1 u^{z-1}(1-u)^{z-1}\,du \qquad (2)$$

and $u \equiv (1+x)/2$, so $du = dx/2$ and

$$\frac{\Gamma(z)\Gamma(z)}{\Gamma(2z)} = \int_0^1 \left(\frac{1+x}{2}\right)^{z-1}\left(1-\frac{1+x}{2}\right)^{z-1}(\tfrac{1}{2}\,dx)$$

$$= \frac{1}{2}\int_0^1 \left(\frac{1+x}{2}\right)^{z-1}\left(\frac{1+x}{2}\right)^{z-1}dx$$

$$= \frac{1}{2^{1+2(z-1)}}\int_0^1 (1-x^2)^{z-1}\,dx$$

$$= 2^{1-2x}\int_0^1 (1-x^2)^{z-1}\,dx. \qquad (3)$$

Now, use the BETA FUNCTION identity

$$B(m, n) = 2\int_0^1 x^{2z-1}(1-x^2)^{z-1}\,dx \qquad (4)$$

to write the above as

$$\frac{\Gamma(z)\Gamma(z)}{\Gamma(2z)} = 2^{1-2z}B(\tfrac{1}{2}, z) = 2^{1-2z}\frac{\Gamma(\frac{1}{2})\Gamma(z)}{\Gamma(z+\frac{1}{2})}. \qquad (5)$$

Solving for $\Gamma(2x)$,

$$\Gamma(2z) = \frac{\Gamma(z)\Gamma(z+\frac{1}{2})2^{2z-1}}{\Gamma(\frac{1}{2})} = \frac{\Gamma(z)\Gamma(z+\frac{1}{2})2^{2z-1}}{\sqrt{\pi}}$$

$$= (2\pi)^{-1/2}2^{2z-1/2}\Gamma(z)\Gamma(z+\tfrac{1}{2}), \qquad (6)$$

since $\Gamma(\frac{1}{2}) = \sqrt{\pi}$.

Legendre Function of the First Kind

The (associated) Legendre function of the first kind $P_n^m(z)$ is the solution to the LEGENDRE DIFFERENTIAL EQUATION which is regular at the origin. For m, n integers and z real, the Legendre function of the first kind simplifies to a polynomial, called the LEGENDRE POLYNOMIAL. The associated Legendre function of first kind is given by the *Mathematica* command LegendreP[n, m, z], and the unassociated function by LegendreP[n, z].

See also LEGENDRE DIFFERENTIAL EQUATION, LEGENDRE FUNCTION OF THE SECOND KIND, LEGENDRE POLYNOMIAL

Legendre Function of the Second Kind

The second solution $Q_1(x)$ to the LEGENDRE DIFFERENTIAL EQUATION. The Legendre functions of the second kind satisfy the same RECURRENCE RELATION as the LEGENDRE POLYNOMIALS. The Legendre functions of the second kind are implemented in *Mathematica* as `LegendreQ[l, x]`. The first few are

$$Q_0(x) = \frac{1}{2}\ln\left(\frac{1+x}{1-x}\right)$$

$$Q_1(x) = \frac{x}{2}\ln\left(\frac{1+x}{1-x}\right) - 1$$

$$Q_2(x) = \frac{3x^2-1}{4}\ln\left(\frac{1+x}{1-x}\right) - \frac{3x}{2}$$

$$Q_3(x) = \frac{5x^3-3x}{4}\ln\left(\frac{1+x}{1-x}\right) - \frac{5x^2}{2} + \frac{2}{3}.$$

The associated Legendre functions of the second kind $Q_l^m(x)$ are the second solution to the associated Legendre differential equation, and are implemented in *Mathematica* as `LegendreQ[l, m, x]` $Q_\nu^\mu(x)$ has DERIVATIVE about 0 of

$$\left[\frac{dQ_\nu^\mu(x)}{dx}\right]_{x=0} = \frac{2^\mu\sqrt{\pi}\cos[\frac{1}{2}\pi(\nu+\mu)]\Gamma(\frac{1}{2}\nu+\frac{1}{2}\mu+1)}{\Gamma(\frac{1}{2}\nu-\frac{1}{2}\mu+\frac{1}{2})}$$

(Abramowitz and Stegun 1972, p. 334). The LOGARITHMIC DERIVATIVE is

$$\left[\frac{d\ln Q_\lambda^\mu(z)}{dz}\right]_{z=0} = 2\exp\{\tfrac{1}{2}\pi i\,\mathrm{sgn}(\Im[z])\}\frac{[\frac{1}{2}(\lambda+\mu)]![\frac{1}{2}(\lambda-\mu)]!}{[\frac{1}{2}(\lambda+\mu-1)]![\frac{1}{2}(\lambda-\mu-1)]!}$$

(Binney and Tremaine 1987, p. 654).

Legendre-Gauss Quadrature

Also called "the" GAUSSIAN QUADRATURE or LEGENDRE QUADRATURE. A GAUSSIAN QUADRATURE over the interval [−1, 1] with WEIGHTING FUNCTION $W(x) = 1$. The ABSCISSAS for quadrature order n are given by the roots of the LEGENDRE POLYNOMIALS $P_n(x)$, which occur symmetrically about 0. The weights are

$$w_i = -\frac{A_{n+1}\gamma_n}{A_n P_n'(x_i)P_{n+1}(x_i)} = \frac{A_n}{A_{n-1}}\frac{\gamma_{n-1}}{P_{n-1}(x_i)P_n'(x_i)}, \tag{1}$$

where A_n is the COEFFICIENT of x^n in $P_n(x)$. For LEGENDRE POLYNOMIALS,

$$A_n = \frac{(2n)!}{2^n(n!)^2}, \tag{2}$$

so

$$\frac{A_{n+1}}{A_n} = \frac{[2(n+1)]!}{2^{n+1}[(n+1)!]^2}\frac{2^n(n!)^2}{(2n)!}$$
$$= \frac{(2n+1)(2n+2)}{2(n+1)^2} = \frac{2n+1}{n+1}. \tag{3}$$

Additionally,

$$\gamma_n = \frac{2}{2n+1}, \tag{4}$$

so

$$w_i = -\frac{2}{(n+1)P_{n+1}(x_i)P_n'(x_i)} = \frac{2}{nP_{n-1}(x_i)P_n'(x_i)}. \tag{5}$$

Using the RECURRENCE RELATION

$$(1-x^2)P_n'(x) = nxP_n(x) + nP_{n-1}(x)$$
$$= (n+1)xP_n(x) - (n+1)P_{n+1}(x) \tag{6}$$

gives

$$w_i = -\frac{2}{(1-x^2)[P_n'(x_i)]^2} = \frac{2(1-x_i^2)}{(n+1)^2[P_{n+1}(x_i)]^2}. \quad (7)$$

The error term is

$$E = \frac{2^{2n+1}(n!)^4}{(2n+1)[(2n)!]^3} f^{(2n)}(\xi). \quad (8)$$

Beyer (1987) gives a table of ABSCISSAS and weights up to $n = 16$, and Chandrasekhar (1960) up to $n = 8$ for n EVEN.

n	x_i	w_i
2	$\pm$ 0.57735	1.000000
3	0	0.888889
	$\pm$ 0.774597	0.555556
4	$\pm$ 0.339981	0.652145
	$\pm$ 0.861136	0.347855
5	0	0.568889
	$\pm$ 0.538469	0.478629
	$\pm$ 0.90618	0.236927

The ABSCISSAS and weights can be computed analytically for small n.

n	x_i	w_i
2	$\pm\frac{1}{3}\sqrt{3}$	1
3	0	$\frac{8}{9}$
	$\pm\frac{1}{5}\sqrt{15}$	$\frac{5}{9}$
4	$\pm\frac{1}{35}\sqrt{525-70\sqrt{30}}$	$\frac{1}{36}(18+\sqrt{30})$
	$\pm\frac{1}{35}\sqrt{525+70\sqrt{30}}$	$\frac{1}{36}(18-\sqrt{30})$
5	0	$\frac{128}{225}$
	$\pm\frac{1}{21}\sqrt{245-14\sqrt{70}}$	$\frac{1}{900}(322+13\sqrt{70})$
	$\pm\frac{1}{21}\sqrt{245+14\sqrt{70}}$	$\frac{1}{900}(322-13\sqrt{70})$

LegendreP

LEGENDRE FUNCTION OF THE FIRST KIND, LEGENDRE POLYNOMIAL

Legendre Polynomial

The Legendre polynomials, sometimes called Legendre functions of the first kind, Legendre coefficients, or ZONAL HARMONICS (Whittaker and Watson 1990, p. 302), are solutions to the LEGENDRE DIFFERENTIAL EQUATION. If l is an INTEGER, they are POLYNOMIALS. The Legendre polynomials $P_n(x)$ are illustrated above for $x \in [0, 1]$ and $n = 1, 2, ..., 5$.

The Legendre polynomials are a special case of the ULTRASPHERICAL FUNCTIONS with $\alpha = 1/2$, a special case of the JACOBI POLYNOMIALS $P_n^{(\alpha,\beta)}$ with $\alpha = \beta = 0$, and can be written as a HYPERGEOMETRIC FUNCTION using Murphy's formula

$$P_n(x) = P_n^{(0,0)}(x) = {}_2F_1(-n, n+1; 1; \tfrac{1}{2}(1-x)) \quad (1)$$

(Bailey 1933; Bailey 1935, p. 101; Koekoek and Swarttouw 1998).

The Rodrigues formula provides the GENERATING FUNCTION

$$P_l(x) = \frac{l}{2^l l!}\frac{d^l}{dx^l}(x^2-1)^l, \quad (2)$$

which yields upon expansion

$$P_l(x) = \frac{1}{2^l}\sum_{k=0}^{\lfloor l/2 \rfloor} \frac{(-1)^k(2l-2k)!}{k!(l-k)!(l-2k)!} x^{l-2k} \quad (3)$$

$$= \frac{1}{2^l}\sum_{k=0}^{\lfloor l/2 \rfloor}(-1)^k \binom{l}{k}\binom{2l-2k}{l} x^{l-2k} \quad (4)$$

where $\lfloor r \rfloor$ is the FLOOR FUNCTION. Additional sum formulas include

$$P_l(x) = \frac{1}{2^l}\sum_{k=0}^{l}\binom{l}{k}^2 (x-1)^{l-k}(x+1)^k \tag{5}$$

$$= \sum_{k=0}^{l}\binom{l}{k}\binom{-l-1}{k}\left(\frac{1-x}{2}\right)^k \tag{6}$$

(Koepf 1998, p. 1). In terms of HYPERGEOMETRIC FUNCTIONS, these can be written

$$P_n(x) = \left(\frac{x-1}{2}\right)^n {}_2F_1(-n,\ -n;\ 1;(x+1)/(x-1)) \tag{7}$$

$$P_n(x) = \binom{2n}{n}\frac{x^n}{2^n}{}_2F_1(-n/2,(1-n)/2;\ 1/2-n;\ x^{-2}) \tag{8}$$

$$P_n(x) = {}_2F_1(-n,\ n+1;\ 1;(1-x)/2) \tag{9}$$

(Koepf 1998, p. 3).

A GENERATING FUNCTION for $P_n(x)$ is given by

$$g(t,\ x) = (1-2xt+t^2)^{-1/2} = \sum_{n=0}^{\infty} P_n(x)t^n. \tag{10}$$

Take $\partial g/\partial t$,

$$-\tfrac{1}{2}(1-2xt+t^2)^{-3/2}(-2x+2t) = \sum_{n=0}^{\infty} nP_n(x)t^{n-1}. \tag{11}$$

Multiply (11) by $2t$,

$$-t(1-2xt+t^2)^{-3/2}(-2x+2t) = \sum_{n=0}^{\infty} 2nP_n(x)t^n \tag{12}$$

and add (10) and (12),

$$(1-2xt+t^2)^{-3/2}[(2xt-2t^2)+(1-2xt+t^2)] = \sum_{n=0}^{\infty}(2n+1)P_n(x)t^n \tag{13}$$

This expansion is useful in some physical problems, including expanding the Heyney-Greenstein phase function and computing the charge distribution on a SPHERE. Another GENERATING FUNCTION is given by

$$\sum_{n=0}^{\infty}\frac{P_n(x)}{n!}z^n = e^{xz}J_0(z\sqrt{1-x^2}), \tag{14}$$

where $J_0(x)$ is a zeroth order BESSEL FUNCTION OF THE FIRST KIND (Koepf 1998, p. 2).

The Legendre polynomials satisfy the RECURRENCE RELATION

$$(l+1)P_{l+1}(x) - (2l+1)xP_l(x) + lP_{l-1}(x) = 0 \tag{15}$$

(Koepf 1998, p. 2).

The Legendre polynomials are orthogonal over $(-1,\ 1)$ with WEIGHTING FUNCTION 1 and satisfy

$$\int_{-1}^{1} P_n(x)P_m(x)\,dx = \frac{2}{2n+1}\delta_{mn}, \tag{16}$$

where δ_{mn} is the KRONECKER DELTA.

A COMPLEX GENERATING FUNCTION is

$$P_l(x) = \frac{1}{2\pi i}\int (1-2zx+z^2)^{-1/2}z^{-l-1}\,dz, \tag{17}$$

and the Schläfli integral is

$$P_l(x) = \frac{(-1)^l}{2^l}\frac{1}{2\pi i}\int\frac{(1-z^2)^l}{(z-x)^{l+1}}\,dz. \tag{18}$$

Additional integrals (Byerly 1959, p. 172) include

$$\int_0^1 P_m(x)\,dx = \begin{cases} 0 & m \text{ even} \neq 0 \\ (-1)^{(m-1)/2}\dfrac{m!!}{m(m+1)(m-1)!!} & m \text{ odd} \end{cases} \tag{19}$$

$$\int_0^1 P_m(x)P_n(x)\,dx = \begin{cases} 0 \\ \quad m,\ n \text{ both even or odd } m\neq n \\ (-1)^{(m+n+1)/2} \\ \quad\times\dfrac{m!n!}{2^{m+n+1}(m-n)(m+n+1)(\frac{1}{2}m)!\{[\frac{1}{2}(n-1)]!\}^2} \\ \quad m \text{ even},\ n \text{ odd} \\ \dfrac{1}{2n+1} \\ \quad m=n. \end{cases} \tag{20}$$

Integrals with weighting functions x and x^2 are given by

$$\int_{-1}^{1} xP_L(x)P_N(x)\,dx = \begin{cases} \frac{2(L+1)}{(2L+1)(2L+3)} & N=L+1 \\ \frac{2L}{(2L-1)(2L+1)} & N=L-1 \end{cases} \tag{21}$$

$$\int_{-1}^{1} x^2P_L(x)P_N(x)\,dx = \begin{cases} \frac{2(L+1)(L+2)}{(2L+1)(2L+3)(2L+5)} & N=L+2 \\ \frac{2(L^2+2L-1)}{(2L-1)(2L+1)(2L+3)} & N=L \\ \frac{2L(L-1)}{(2L-3)(2L-1)(2L+1)} & N=L-2 \end{cases} \tag{22}$$

(Arfken 1985, p. 700). An additional identity is

$$1-[P_n(x)]^2 = \sum_{\nu=1}^{n}\frac{1-x^2}{1-x_\nu^2}\left[\frac{P_n(x)}{P_n'(x_\nu)(x-x_\nu)}\right]^2, \tag{23}$$

where x_ν is the νth root of $P_n(x)$ (Szego 1975, p. 348).

The first few Legendre polynomials are

$$\begin{aligned} P_0(x) &= 1 \\ P_1(x) &= x \\ P_2(x) &= \tfrac{1}{2}(3x^2 - 1) \\ P_3(x) &= \tfrac{1}{2}(5x^3 - 3x) \\ P_4(x) &= \tfrac{1}{8}(35x^4 - 30x^2 + 3) \\ P_5(x) &= \tfrac{1}{8}(63x^5 - 70x^3 + 15x) \\ P_6(x) &= \tfrac{1}{16}(231x^6 - 315x^4 + 105x^2 - 5). \end{aligned}$$

The first few POWERS in terms of Legendre polynomials are

$$\begin{aligned} x &= P_1 \\ x^2 &= \tfrac{1}{3}[P_0(x) + 2P_2(x)] \\ x^3 &= \tfrac{1}{5}[3P_1(x) + 2P_3(x)] \\ x^4 &= \tfrac{1}{35}[7P_0(x) + 20P_2(x) + 8P_4(x)] \\ x^5 &= \tfrac{1}{63}[27P_1(x) + 28P_3(x) + 8P_5(x)] \\ x^6 &= \tfrac{1}{231}[33P_0(x) + 110P_2(x) + 72P_4(x) + 16P_6(x)]. \end{aligned}$$

For Legendre polynomials and POWERS up to exponent 12, see Abramowitz and Stegun (1972, p. 798).

The Legendre POLYNOMIALS can also be generated using GRAM-SCHMIDT ORTHONORMALIZATION in the OPEN INTERVAL (−1, 1) with the WEIGHTING FUNCTION 1.

$$P_0(x) = 1 \tag{24}$$

$$P_1(x) = \left[x - \frac{\int_{-1}^{1} x\,dx}{\int_{-1}^{1} dx}\right] \cdot 1$$

$$= x - \frac{\tfrac{1}{2}[x^2]_{-1}^{1}}{[x]_{-1}^{1}} = x - \frac{\tfrac{1}{2}(1-1)}{1-(-1)} = x \tag{25}$$

$$P_2(x) = \left[x - \frac{\int_{-1}^{1} x^3\,dx}{\int_{-1}^{1} x^2\,dx}\right] - \left[\frac{\int_{-1}^{1} x^2\,dx}{\int_{-1}^{1} dx}\right] \cdot 1$$

$$= \left[x - \frac{\tfrac{1}{4}[x^4]_{-1}^{1}}{\tfrac{1}{3}[x^3]_{-1}^{1}}\right] x - \frac{\tfrac{1}{3}[x^3]_{-1}^{1}}{[x]_{-1}^{1}} = x^2 - \tfrac{1}{3} \tag{26}$$

$$P_3(x) = \left[x - \frac{\int_{-1}^{1} x(x^2 - \tfrac{1}{3})^2\,dx}{\int_{-1}^{1} (x^2 - \tfrac{1}{3})^2\,dx}\right](x^2 - \tfrac{1}{3}) - \left[\frac{\int_{-1}^{1} (x^2 - \tfrac{1}{3})^2\,dx}{\int_{-1}^{1} x^2\,dx}\right] x$$

$$= x\left[x^2 - \tfrac{1}{3} - \frac{(\tfrac{1}{5} - \tfrac{2}{9} + \tfrac{1}{9})x}{\tfrac{1}{3}}\right]$$

$$= x^3 - \tfrac{1}{3}x - 3(\tfrac{1}{5} - \tfrac{1}{9})$$

$$= x^3 - x(\tfrac{1}{3} + \tfrac{3}{5} - \tfrac{1}{3}) = x^3 - \tfrac{3}{5}x. \tag{27}$$

Normalizing so that $P_n(1) = 1$ gives the expected Legendre polynomials.

The "shifted" Legendre polynomials are a set of functions analogous to the Legendre polynomials, but defined on the interval (0, 1). They obey the ORTHOGONALITY relationship

$$\int_0^1 \bar{P}_m(x)\bar{P}_n(x)\,dx = \frac{1}{2n+1}\,\delta_{mn}. \tag{28}$$

The first few are

$$\begin{aligned} \bar{P}_0(x) &= 1 \\ \bar{P}_1(x) &= 2x - 1 \\ \bar{P}_2(x) &= 6x^2 - 6x + 1 \\ \bar{P}_3(x) &= 20x^3 - 30x^2 + 12x - 1. \end{aligned}$$

The associated Legendre polynomials $P_l^m(x)$ are solutions to the associated LEGENDRE DIFFERENTIAL EQUATION, where l is a POSITIVE INTEGER and $m = 0$, ..., l. They can be given in terms of the unassociated polynomials by

$$P_l^m(x) = (-1)^m (1 - x^2)^{m/2} \frac{d^m}{dx^m} P_l(x)$$

$$= \frac{(-1)^m}{2^l l!} (1 - x^2)^{m/2} \frac{d^{l+m}}{dx^{l+m}} (x^2 - 1)^l, \tag{29}$$

where $P_l(x)$ are the unassociated LEGENDRE POLYNOMIALS. Note that some authors (e.g., Arfken 1985, p. 668) omit the CONDON-SHORTLEY PHASE $(-1)^m$, while others include it (e.g., Abramowitz and Stegun 1972, Press *et al.* 1992, and the `LegendreP`$[l, m, z]$ command of *Mathematica*). Abramowitz and Stegun (1972, p. 332) use the notation

$$P_{lm}(X) \equiv (-1)^m P_m^l(x) \tag{30}$$

to distinguish these two cases.

Associated polynomials are sometimes called FERRERS' FUNCTIONS (Sansone 1991, p. 246). If $m = 0$, they reduce to the unassociated POLYNOMIALS. The associated Legendre functions are part of the SPHERICAL HARMONICS, which are the solution of LAPLACE'S EQUATION in SPHERICAL COORDINATES. They are ORTHOGONAL over [−1, 1] with the WEIGHTING FUNCTION 1

$$\int_{-1}^{1} P_l^m(x)P_{l'}^m(x)\,dx = \frac{2}{2l+1}\,\frac{(l+m)!}{(l-m)!}\,\delta_{ll'}, \tag{31}$$

and ORTHOGONAL over [−1, 1] with respect to m with the WEIGHTING FUNCTION $(1 - x^2)^{-2}$

$$\int_{-1}^{1} P_l^m(x) P_l^{m'}(x) \frac{dx}{1-x^2} = \frac{(l+m)!}{m(l-m)!} \delta_{mm'}. \quad (32)$$

The associated Legendre polynomials also obey the following RECURRENCE RELATIONS

$$(l-m)P_l^m(x) = x(2l-1)P_{l-1}^m(x) - (l+m-1)P_{l-2}^m(x). \quad (33)$$

Letting $x \equiv \cos\theta$ (commonly denoted μ in this context),

$$\frac{dP_l^m(\mu)}{d\theta} = \frac{l\mu P_l^m(\mu) - (l+m)P_{l-1}^m(\mu)}{\sqrt{1-\mu^2}} \quad (34)$$

$$(2l+1)\mu P_l^m(\mu) = (l+m)P_{l-1}^m(\mu) + (l-m+1)P_{l+1}^m(\mu). \quad (35)$$

An identity relating associated POLYNOMIALS with NEGATIVE m to the corresponding functions with POSITIVE m is

$$P_l^{-m}(x) = (-1)^m \frac{(l-m)!}{(l+m)!} P_l^m(x). \quad (36)$$

Additional identities are

$$P_l^l(x) = (-1)^l (2l-1)!!(1-x^2)^{1/2} \quad (37)$$

$$P_{l+1}^l(x) = x(2l+1)P_l^l(x). \quad (38)$$

Written in terms of x and using the convention without a leading factor of $(-1)^m$ (Arfken 1985, p. 669), the first few associated Legendre polynomials are

$$P_0^0(x) = 1$$
$$P_1^0(x) = x$$
$$P_1^1(x) = -(1-x^2)^{1/2}$$
$$P_2^0(x) = \tfrac{1}{2}(3x^2-1)$$
$$P_2^1(x) = -3x(1-x^2)^{1/2}$$
$$P_2^2(x) = 3(1-x^2)$$
$$P_3^0(x) = \tfrac{1}{2}x(5x^2-3)$$
$$P_3^1(x) = \tfrac{3}{2}(1-5x^2)(1-x^2)^{1/2}$$
$$P_3^2(x) = 15x(1-x^2)$$
$$P_3^3(x) = -15(1-x^2)^{3/2}$$
$$P_4^0(x) = \tfrac{1}{8}(35x^4-30x^2+3)$$
$$P_4^1(x) = \tfrac{5}{2}x(3-7x^2)(1-x^2)^{1/2}$$
$$P_4^2(x) = \tfrac{15}{2}(7x^2-1)(1-x^2)$$
$$P_4^3(x) = -105x(1-x^2)^{3/2}$$
$$P_4^4(x) = 105(1-x^2)^2$$
$$P_5^0(x) = \tfrac{1}{8}x(63x^4-70x^2+15).$$

Written in terms $x = \cos\theta$ (commonly written $\mu = \cos\theta$), the first few become

$$P_0^0(\cos\theta) = 1$$
$$P_1^0(\cos\theta) = \cos\theta$$
$$P_1^1(\cos\theta) = -\sin\theta$$
$$P_2^0(\cos\theta) = \tfrac{1}{2}(3\cos^2\theta - 1)$$
$$P_2^1(\cos\theta) = -3\sin\theta\cos\theta$$
$$P_2^2(\cos\theta) = 3\sin^2\theta$$
$$P_3^0(\cos\theta) = \tfrac{1}{2}\cos\theta(5\cos^2\theta - 3)$$
$$P_3^1(\cos\theta) = -\tfrac{3}{2}(5\cos^2\theta - 1)\sin\theta$$
$$P_3^2(\cos\theta) = 15\cos\theta\sin^2\theta$$
$$P_3^3(\cos\theta) = -15\sin^3\theta.$$

The derivative about the origin is

$$\left[\frac{dP_\nu^\mu(x)}{dx}\right]_{x=0} = \frac{2^{\mu+1}\sin[\frac{1}{2}\pi(\nu+\mu)]\Gamma(\frac{1}{2}\nu+\frac{1}{2}\mu+1)}{\pi^{-1/2}\Gamma(\frac{1}{2}\nu-\frac{1}{2}\mu+\frac{1}{2})} \quad (39)$$

(Abramowitz and Stegun 1972, p. 334), and the logarithmic derivative is

$$\left[\frac{d\ln P_\lambda^\mu(z)}{dz}\right]_{z=0} = 2\tan[\tfrac{1}{2}\pi(\lambda+\mu)] \times \frac{[\frac{1}{2}(\lambda+\mu)]![\frac{1}{2}(\lambda-\mu)]!}{[\frac{1}{2}(\lambda+\mu-1)]![\frac{1}{2}(\lambda-\mu-1)]!}. \quad (40)$$

(Binney and Tremaine 1987, p. 654).

Legendre Polynomial of the Second Kind

LEGENDRE FUNCTION OF THE SECOND KIND

LegendreQ

LEGENDRE FUNCTION OF THE SECOND KIND

Legendre Quadrature

LEGENDRE-GAUSS QUADRATURE

Legendre Relation

Let $E(k)$ and $K(k)$ be complete ELLIPTIC INTEGRALS OF THE FIRST and SECOND KINDS, with $E'(k)$ and $K'(k)$ the complementary integrals. Then

$$E(k)K'(k)+E'(k)K(k)-K(k)K'(k)=\tfrac{1}{2}\pi.$$

Legendre's Chi-Function

Portions of this entry contributed by Joe Keane.

The function defined by

$$\chi_\nu(z)=\sum_{k=0}^{\infty}\frac{z^{2k+1}}{(2k+1)^\nu} \quad (1)$$

for integral $\nu=2, 3, ...$ It is related to the POLYLOGARITHM by

$$\chi_\nu(z)=\tfrac{1}{2}[\mathrm{Li}_\nu(z)-\mathrm{Li}_\nu(-z)] \quad (2)$$

$$=\mathrm{Li}_\nu(z)-2^{-\nu}\mathrm{Li}_\nu(z^2) \quad (3)$$

and to the LERCH TRANSCENDENT by

$$\chi_\nu(z)=2^{-\nu}z\Phi(z^2,\ n,\ \tfrac{1}{2}). \quad (4)$$

It takes the special values

$$\chi_2(i)=iK \quad (5)$$

$$\chi_2(\sqrt{2}-1)=\tfrac{1}{16}\pi^2-\tfrac{1}{4}[\ln(\sqrt{2}+1)]^2 \quad (6)$$

$$\chi_2(\tfrac{1}{2}(\sqrt{5}-1))=\tfrac{1}{12}\pi^2-\tfrac{3}{4}[\ln(\tfrac{1}{2}(\sqrt{5}+1))]^2 \quad (7)$$

$$\chi_2(\sqrt{5}-2)=\tfrac{1}{24}\pi^2-\tfrac{3}{4}[\ln(\tfrac{1}{2}(\sqrt{5}+1))]^2 \quad (8)$$

$$\chi_2(-1)=-\tfrac{1}{8}\pi^2 \quad (9)$$

$$\chi_2(1)=\tfrac{1}{8}\pi^2, \quad (10)$$

where I is the imaginary unit and K is CATALAN'S CONSTANT (Lewin, p. 19). Other special values include

$$\chi_n(1)=\lambda(n) \quad (11)$$

$$\chi_n(1)=i\beta(n), \quad (12)$$

where $\lambda(n)$ is the DIRICHLET LAMBDA FUNCTION and $\beta(n)$ is the DIRICHLET BETA FUNCTION.

Legendre Series

Because the LEGENDRE FUNCTIONS OF THE FIRST KIND form a COMPLETE ORTHOGONAL BASIS, any FUNCTION may be expanded in terms of them

$$f(x) = \sum_{n=0}^{\infty} a_n P_n(x). \qquad (1)$$

Now, multiply both sides by $P_m(x)$ and integrate

$$\int_{-1}^{1} P_m(x) f(x)\, dx = \sum_{n=0}^{\infty} a_n \int_{-1}^{1} P_n(x) P_m(x)\, dx. \qquad (2)$$

But

$$\int_{-1}^{1} P_n(x) P_m(x)\, dx = \frac{2}{2m+1}\, \delta_{mn}, \qquad (3)$$

where δ_{mn} is the KRONECKER DELTA, so

$$\int_{-1}^{1} P_m(x) f(x)\, dx = \sum_{n=0}^{\infty} a_n \frac{2}{2m+1}\, \delta_{mn}$$
$$= \frac{2}{2m+1}\, a_m \qquad (4)$$

and

$$a_m = \frac{2m+1}{2} \int_{-1}^{1} P_m(x) f(x)\, dx. \qquad (5)$$

See also FOURIER SERIES, JACKSON'S THEOREM, LEGENDRE POLYNOMIAL, MACLAURIN SERIES, PICONE'S THEOREM, TAYLOR SERIES

Legendre's Factorization Method

A PRIME FACTORIZATION ALGORITHM in which a sequence of TRIAL DIVISORS is chosen using a QUADRATIC SIEVE. By using QUADRATIC RESIDUES of N, the QUADRATIC RESIDUES of the factors can also be found.

See also PRIME FACTORIZATION ALGORITHMS, QUADRATIC RESIDUE, QUADRATIC SIEVE, TRIAL DIVISOR

Legendre's Formula

Counts the number of POSITIVE INTEGERS less than or equal to a number x which are not divisible by any of the first a PRIMES,

$$\phi(x, a) = \lfloor x \rfloor - \sum \left\lfloor \frac{x}{p_i} \right\rfloor + \sum \left\lfloor \frac{x}{p_i p_j} \right\rfloor - \sum \left\lfloor \frac{x}{p_i p_j p_k} \right\rfloor + \ldots, \qquad (1)$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION. Taking $a = x$ gives

$$\phi(x, x) = \pi(x) - \pi(\sqrt{x}) + 1$$
$$= \lfloor x \rfloor - \sum_{p_i \leq \sqrt{x}} \left\lfloor \frac{x}{pi} \right\rfloor + \sum_{p_i < p_j \leq \sqrt{x}} \left\lfloor \frac{x}{p_i p_j} \right\rfloor$$
$$- \sum_{p_i < p_j < p_k \leq \sqrt{x}} \left\lfloor \frac{x}{p_i p_j p_k} \right\rfloor + \ldots, \qquad (2)$$

where $\pi(n)$ is the PRIME COUNTING FUNCTION. Legendre's formula holds since one more than the number of PRIMES in a range equals the number of INTEGERS minus the number of composites in the interval.

Legendre's formula satisfies the RECURRENCE RELATION

$$\phi(x, a) = \phi(x, a-1) - \phi\left(\frac{x}{p_a}, a-1\right). \qquad (3)$$

Let $m_k \equiv p_1 p_2 \cdots p_k$, then

$$\phi(m_k, k) = \lfloor m_k \rfloor - \sum \left\lfloor \frac{m_k}{p_i} \right\rfloor + \sum \left\lfloor \frac{m_k}{p_i p_j} \right\rfloor - \ldots$$

$$= m_k - \sum \frac{m_k}{p_i} + \sum \frac{m_k}{p_i p_j} - \ldots$$

$$= m_k \left(1 - \frac{1}{p-1}\right)\left(1 - \frac{1}{p^2}\right) \cdots \left(1 - \frac{1}{p_k}\right)$$

$$= \prod_{i=1}^{k} (p_i - 1) = \phi(m_k), \qquad (4)$$

where $\phi(n)$ is the TOTIENT FUNCTION, and

$$\phi(sm_k + t, k) = s\phi(m_k) + \phi(t, k), \qquad (5)$$

where $0 \le t \le m_k$. If $t > m_k/2$, then

$$\phi(t, k) = \phi(m_k) - \phi(m_k - t - 1, k). \qquad (6)$$

Note that $\phi(n, n)$ is not practical for computing $\pi(n)$ for large arguments. A more efficient modification is MEISSEL'S FORMULA.

Legendre's Quadratic Reciprocity Law

QUADRATIC RECIPROCITY LAW

Legendre Sum

LEGENDRE'S FORMULA

Legendre Symbol

The Legendre symbol is a number theoretic function $\left(\frac{m}{n}\right)$ which is defined to be equal to ± 1 depending on whether m is a QUADRATIC RESIDUE modulo n. The definition is sometimes generalized to have value 0 if $m|n$,

$$\left(\frac{m}{n}\right) = (m|n)$$

$$\equiv \begin{cases} 0 & \text{if } m|n \\ 1 & \text{if } m \text{ is a quadratic residue modulo } n \\ -1 & \text{if } m \text{ is a quadratic nonresidue modulo } n. \end{cases} \qquad (1)$$

If n is an ODD PRIME, then the JACOBI SYMBOL reduces to the Legendre symbol. The Legendre symbol is implemented in *Mathematica* via the JACOBI SYMBOL, `JacobiSymbol[`n`, `m`]`.

The Legendre symbol obeys the identity

$$\left(\frac{ab}{p}\right) = \left(\frac{a}{p}\right)\left(\frac{b}{p}\right). \qquad (2)$$

Particular identities include

$$\left(\frac{-1}{p}\right) = (-1)^{(p-1)/2} \qquad (3)$$

$$\left(\frac{2}{p}\right) = (-1)^{(p^2-1)/8} \qquad (4)$$

$$\left(\frac{3}{p}\right) = \begin{cases} 1 & \text{if } p \equiv 1 \pmod 6 \\ -1 & \text{if } p \equiv 5 \pmod 6 \end{cases} \qquad (5)$$

$$\left(\frac{5}{p}\right) = \begin{cases} 1 & \text{if } p \equiv \pm 1 \pmod{10} \\ -1 & \text{if } p \equiv \pm 7 \pmod{10} \end{cases} \qquad (6)$$

(Nagell 1951, p. 144), as well as the general

$$\left(\frac{q}{p}\right) = \left(\frac{p}{q}\right)(-1)^{[(p-1)/2][(q-1)/2]}. \qquad (7)$$

Legendre Transform

The Legendre transform of a sequence $\{c_k\}$ is the sequence $\{a_k\}$ with terms given by

$$a_n = \sum_{k=0}^{n} c_k \binom{n}{k}\binom{n+k}{k},$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT (Jin and Dickinson 2000). Strehl (1994) and Schmidt (1995) showed that

$$\sum_{k=0}^{n} \binom{n}{k}^2 \binom{n+k}{k}^2 = \sum_{k=0}^{n} \binom{n}{k}\binom{n+k}{k} \sum_{j=0}^{k} \binom{k}{j}^3.$$

Legendre Transformation

Given a function of two variables

$$df = \frac{\partial f}{\partial x}\,dx + \frac{\partial f}{\partial y}\,dy \equiv u\,dx + v\,dy, \tag{1}$$

change the differentials from dx and dy to du and dy with the transformation

$$g \equiv f - ux \tag{2}$$

$$\begin{aligned} dg &= df - u\,dx - x\,du = u\,dx + v\,dy - u\,dx - x\,du \\ &= v\,dy - x\,du. \end{aligned} \tag{3}$$

Then

$$x \equiv -\frac{\partial g}{\partial u}. \tag{4}$$

$$v \equiv \frac{\partial g}{\partial y}. \tag{5}$$

Lehmer Continued Fraction

A CONTINUED FRACTION OF THE FORM

$$b_0 + \cfrac{e_1}{b_1 + \cfrac{e_2}{b_2 + \cfrac{e_3}{b_3 + \ldots}}}$$

where $(b_i,\ e_{i+1}) = (1,\ 1)$ or $(2,\ -1)$ for $x \in [1, 2)$ an IRRATIONAL NUMBER (Lehmer 1994, Dajani and Kraaikamp 1999).

Lehmer Method

LEHMER-SCHUR METHOD

Lehmer Number

A number generated by a generalization of a LUCAS SEQUENCE. Let α and β be COMPLEX NUMBERS with

$$\alpha + \beta = \sqrt{R} \tag{1}$$

$$\alpha\beta = Q, \tag{2}$$

where Q and R are RELATIVELY PRIME NONZERO INTEGERS and α/β is a ROOT OF UNITY. Then the Lehmer numbers are

$$U_n(\sqrt{R},\ Q) = \frac{\alpha^n - \beta^n}{\alpha - \beta}, \tag{3}$$

and the companion numbers

$$V_n\left(\sqrt{R},\ Q\right) = \begin{cases} \dfrac{\alpha^n + \beta^n}{\alpha + \beta} & \text{for } n \text{ odd} \\ \alpha^n + \beta^n & \text{for } n \text{ even} \end{cases} \tag{4}$$

Lehmer's Conjecture

LEHMER'S MAHLER MEASURE PROBLEM

Lehmer's Constant

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Lehmer (1938) showed that every POSITIVE IRRATIONAL NUMBER x has a unique infinite continued cotangent representation OF THE FORM

$$x = \cot\left[\sum_{k=0}^{\infty}(-1)^k \cot^{-1} b_k\right],$$

where the b_ks are NONNEGATIVE and

$$b_k \geq (b_{k-1})^2 + b_{k-1} + 1.$$

The case for which the convergence is slowest occurs when the inequality is replaced by equality, giving $c_0 = 0$ and

$$c_k = (c_{k-1})^2 + c_{k-1} + 1$$

for $k \geq 1$. The first few values are c_k are 0, 1, 3, 13, 183, 33673, ... (Sloane's A024556), resulting in the constant

$$\begin{aligned}\xi &= \cot(\cot^{-1} 0 - \cot^{-1} 1 + \cot^{-1} 3 - \cot^{-1} 13 \\ &+\cot^{-1} 183 - \cot^{-1} 33673 + \cot^{-1} 1133904603 \\ &-\cot^{-1} 1285739649838492213 + \ldots + (-1)^k c_k \ldots) \\ &= \cot\left(\tfrac{1}{4}\pi + \cot^{-1} 3 - \cot^{-1} 13 \right.\\ &+\cot^{-1} 183 - \cot^{-1} 33673 + \cot^{-1} 1133904603 \\ &\left.-\cot^{-1} 1285739649838492213 + \ldots + (-1)^k c_k \ldots\right) \\ &= 0.59263271\ldots\end{aligned}$$

(Sloane's A030125). ξ is not an ALGEBRAIC NUMBER of degree less than 4, but Lehmer's approach cannot show whether or not ξ is TRANSCENDENTAL.

See also ALGEBRAIC NUMBER, TRANSCENDENTAL NUMBER

Lehmer's Formula

A FORMULA related to MEISSEL'S FORMULA.

$$\begin{aligned}\pi(x) &= \lfloor x \rfloor - \sum_{i=1}^{a} \left\lfloor \frac{x}{p_i} \right\rfloor + \sum_{1 \leq i \leq j \leq a} \left\lfloor \frac{x}{p_i p_j} \right\rfloor - \ldots \\ &+\tfrac{1}{2}(b + a - 2)(b - a + 1) - \sum_{a \leq i \leq b} \pi\left(\frac{x}{p_i}\right) \\ &- \sum_{i=a+1}^{c} \sum_{j=i}^{b_i} \left[\pi\left(\frac{x}{p_i p_j}\right) - (j-1)\right],\end{aligned}$$

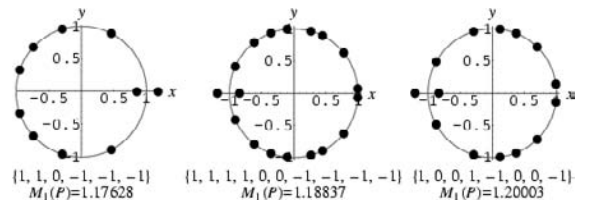
where $\lfloor x \rfloor$ is the FLOOR FUNCTION,

$$a \equiv \pi(x^{1/4})$$

$$b \equiv \pi(x^{1/2})$$

$$b_i \equiv \left(\pi\sqrt{x/p_i}\right)$$

$$c \equiv \pi(x^{1/3}),$$



and $\pi(n)$ is the PRIME COUNTING FUNCTION.

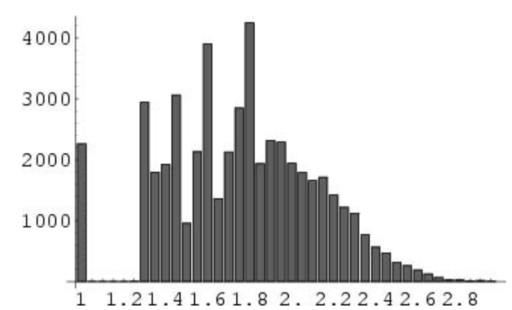
Lehmer's Mahler Measure Problem

Portions of this entry contributed by KEVIN O'BRYANT



An UNSOLVED PROBLEM in mathematics attributed to Lehmer that concerns the minimum MAHLER MEASURE $M_1(P)$ for a UNIVARIATE POLYNOMIAL $P(x)$ that is not a product of CYCLOTOMIC POLYNOMIALS. Lehmer conjectured that if $P(x)$ is such a polynomial with integer coefficients, then

$$\begin{aligned}M_1(P) &\geq M_1(1 - x + x^3 - x^4 + x^5 - x^6 + x^7 - x^9 + x^{10}) \\ &= m^*, \end{aligned} \tag{1}$$

where $m^* \approx 1.1762$ is the largest positive root of this polynomial. The roots of this polynomial, plotted in the left figure above, are very special, since 8 of the 10 lie on the UNIT CIRCLE in the COMPLEX PLANE. The roots of the polynomials (represented by half their coefficients) giving the two next smallest known Mahler measures are also illustrated above (Mossinghoff, p. S11).

The best current bound is that of Smyth (1971), who showed that $M(F) > \theta_1$, where F is a nonzero nonreciprocal polynomial that is not a product of CYCLOTOMIC POLYNOMIALS (Everest 1999), and $\theta_1 \approx 1.324$ is the real root of $x^3 - x - 1 = 0$. Generalizations of Smyth's result have been constructed by Lloyd-Smith (1985) and Dubickas (1997).

In general, the smallest MAHLER MEASURES occur for polynomials with integers coefficients that are small in absolute value. The histogram above shows the distribution of measures for random (−1, 0, 1)-poly-

nomials of random orders 1 to 10. Mossinghoff (1998) gives a table of the smallest known Mahler measures for polynomial degrees up to $d = 24$.

Lehmer's Problem

LEHMER'S MAHLER MEASURE PROBLEM, LEHMER'S TOTIENT PROBLEM

Lehmer's Theorem

FERMAT'S LITTLE THEOREM CONVERSE

Lehmer's Totient Problem

Do there exist any COMPOSITE NUMBERS n such that $\phi(n)|(n-1)$, where $\phi(n)$ is the TOTIENT FUNCTION? No such numbers are known. In 1932, Lehmer showed that such an n must be ODD and SQUAREFREE, and that the number of distinct PRIME FACTORS $d(7) \geq 7$. This was subsequently extended to $d(n) \geq 11$. The best current results are $n > 10^{20}$ and $d(n) \geq 14$ (Cohen and Hagis 1980), if $30 \nmid n$, then $d(n) \geq 26$ (Wall 1980), and if $3|n$ then $d(n) \geq 213$ and $n \geq 5.5 \times 10^{570}$ (Lieuwens 1970).

Lehmus' Theorem

STEINER-LEHMUS THEOREM

Leibniz Criterion

Also known as the ALTERNATING SERIES TEST. Given a SERIES

$$\sum_{n=1}^{\infty} (-1)^{n+1} a_n$$

with $a_n > 0$, if a_n is monotonic decreasing as $n \to \infty$ and

$$\lim_{n \to \infty} a_n = 0$$

then the series CONVERGES.

Leibniz Harmonic Triangle

$$\frac{1}{1}$$

$$\frac{1}{2} \quad \frac{1}{2}$$

$$\frac{1}{3} \quad \frac{1}{6} \quad \frac{1}{3}$$

$$\frac{1}{4} \quad \frac{1}{12} \quad \frac{1}{12} \quad \frac{1}{4}$$

$$\frac{1}{5} \quad \frac{1}{20} \quad \frac{1}{30} \quad \frac{1}{20} \quad \frac{1}{5}$$

(Sloane's A003506). In the Leibniz harmonic triangle, each FRACTION is the sum of numbers below it, with the initial and final entry on each row one over the corresponding entry in PASCAL'S TRIANGLE. The DENOMINATORS in the second diagonals are 6, 12, 20, 30, 42, 56, ... (Sloane's A007622).

Leibniz Identity

$$\frac{d^n}{dx^n}(uv) = \frac{d^n u}{dx^n}\, v + \binom{n}{1}\frac{d^{n-1}u}{dx^{n-1}}\,\frac{dv}{dx} + \ldots + \binom{n}{r}$$
$$\times \frac{d^{n-r}u}{dx^{n-r}}\,\frac{d^n v}{dx^r} + \ldots + u\,\frac{d^n v}{dx^n}$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT. This can also be written explicitly as

$$D^n f(t)g(t) = \sum_{k=0}^{n}\binom{n}{k} D^k f(t) D^{n-k} g(t)$$

(Roman 1980).

Leibniz Integral Rule

$$\frac{\partial}{\partial z}\int_{a(z)}^{b(z)} f(x, z)\, dx$$
$$= \int_{a(z)}^{b(z)} \frac{\partial f}{\partial z}\, dx + f(b(z), z)\frac{\partial b}{\partial z} - f(a(z), z)\,\frac{\partial a}{\partial z}.$$

The differentiation of a definite integral whose limits are functions of the differential variable. The rule can be used to evaluate certain unusual definite integrals such as

$$\phi(\alpha) = \int_0^\pi \ln(1 - 2\alpha\cos x + \alpha^2)\, dx = 2\pi \ln|\alpha|$$

for $|\alpha| > 1$ (Woods 1926). Although the symbolic mathematics program *Mathematica* gives *an* analytic solution to this integral, it gives the solution in a much more complicated form.

Feynman (1997) recalled seeing the method in Woods (1926) and remarked "So because I was self-taught using that book, I had peculiar methods for doing integrals," and "I used that one damn tool again and again."

Leibniz Series

The SERIES for the INVERSE TANGENT,

$$\tan^{-1} x = x - \tfrac{1}{3}x^3 + \tfrac{1}{5}x^5 + \ldots.$$

Plugging in $x = 1$ gives GREGORY'S FORMULA

$$\tfrac{1}{4}\pi = 1 - \tfrac{1}{3} + \tfrac{1}{5} - \tfrac{1}{7} + \tfrac{1}{9} - \ldots.$$

This series is intimately connected with the number of representations of n by k squares $r_k(n)$, and also with GAUSS'S CIRCLE PROBLEM (Hilbert and Cohn-Vossen 1999, pp. 27–9).

Lemarié's Wavelet

A wavelet used in multiresolution representation to analyze the information content of images. The WAVELET is defined by

$$H(\omega) = \left[2(1-u)^4 \frac{315 - 420u + 126u^2 - 4u^3}{315 - 420v + 126v^2 - 4v^3} \right]^{1/2},$$

where

$$u \equiv \sin^2\left(\tfrac{1}{2}\,\omega\right)$$

$$v \equiv \sin^2 \omega$$

(Mallat 1989).

CAUCHY-FROBENIUS LEMMA, PÓLYA ENUMERATION THEOREM

Lemniscate

A polar curve also called LEMNISCATE OF BERNOULLI which is the LOCUS of points the product of whose distances from two fixed points (called the FOCI) a distance $2a$ away is the constant a^2. Letting the FOCI be located at $(\pm a,\ 0)$, the Cartesian equation is

$$[(x-a)^2+y^2][(x+a)^2+y^2]=a^4, \tag{1}$$

which can be rewritten

$$x^4+y^4+2x^2y^2=2a^2(x^2-y^2). \tag{2}$$

Letting $a' \equiv \sqrt{2}a$, the POLAR COORDINATES are given by

$$r^2 = a^2 \cos(2\theta). \tag{3}$$

An alternate form is

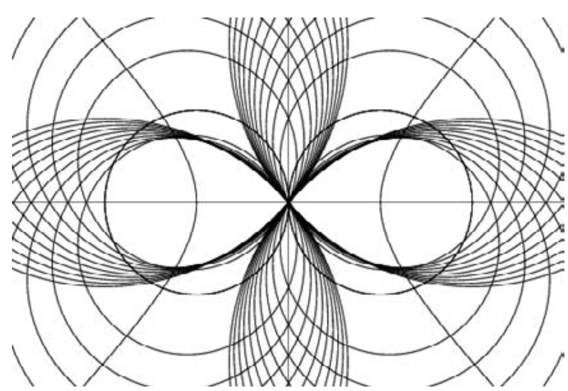
$$r^2 = a^2 \sin(2\theta) \tag{4}$$

The PARAMETRIC EQUATIONS for the lemniscate are

$$x = \frac{a \cos t}{1+\sin^2 t}. \tag{5}$$

$$y = \frac{a \sin t \cos t}{1+\sin^2 t}. \tag{6}$$

The bipolar equation of the lemniscate is



$$rr' = \tfrac{1}{2}\,a^2, \tag{7}$$

and in PEDAL COORDINATES with the PEDAL POINT at the center, the equation is

$$pa^2 = r^3. \tag{8}$$

The two-center BIPOLAR COORDINATES equation with origin at a FOCUS is

$$r_1 r_2 = c^2. \tag{9}$$

The lemniscate can also be generated as the ENVELOPE of circles centered on a RECTANGULAR HYPERBOLA and passing through the center of the HYPERBOLA (Wells 1991).

Jakob Bernoulli published an article in *Acta Eruditorum* in 1694 in which he called this curve the *lemniscus* (Latin for "a pendant ribbon"). Jakob Bernoulli was not aware that the curve he was describing was a special case of CASSINI OVALS which

had been described by Cassini in 1680. The general properties of the lemniscate were discovered by G. Fagnano in 1750 (MacTutor Archive). Gauss's and Euler's investigations of the ARC LENGTH of the curve led to later work on ELLIPTIC FUNCTIONS.

The lemniscate is the INVERSE CURVE of the HYPERBOLA with respect to its center.

The CURVATURE of the lemniscate is

$$\kappa = \frac{3\sqrt{2}\cos t}{\sqrt{3-\cos(2t)}}. \tag{10}$$

The ARC LENGTH is more problematic. Using the polar form,

$$ds^2 = dr^2 + r^2\, d\theta^2 \tag{11}$$

so

$$ds = \sqrt{1+\left(r\,\frac{d\theta}{dr}\right)^2}\, dr. \tag{12}$$

But we have

$$2r\, dr = 2a^2 \sin(2\theta)\, d\theta \tag{13}$$

$$r\,\frac{dr}{d\theta} = \frac{r^2}{a^2 \sin(2\theta)} \tag{14}$$

$$\left(r\,\frac{d\theta}{dr}\right)^2 = \frac{r^4}{a^4 \sin^2(2\theta)} = \frac{r^4}{a^4[1-\cos^2(2\theta)]} = \frac{r^4}{a^4 - r^4}, \tag{15}$$

so

$$ds = \sqrt{1+\frac{r^4}{a^4-r^4}}\, dr = \sqrt{\frac{a^4}{a^4-r^4}}\, dr = \frac{a^2}{\sqrt{a^4-r^4}}\, dr = \frac{dr}{\sqrt{1-\left(\frac{r}{a}\right)^4}}, \tag{16}$$

and

$$L = \int_0^a ds = 2\int_0^a \frac{ds}{dr}\, dr = 2\int_0^a \frac{dr}{\sqrt{1-\left(\frac{r}{a}\right)^4}}. \tag{17}$$

Let $t \equiv r/a$, so $dt = dr/a$, and

$$L = 2a\int_0^1 (1-t^4)^{-1/2}\, dt \tag{18}$$

which, as shown in LEMNISCATE FUNCTION, is given analytically by

$$L = \sqrt{2}aK\left(\frac{1}{\sqrt{2}}\right) = \frac{\Gamma^2\left(\frac{1}{4}\right)}{2^{3/2}\sqrt{\pi}}\, a. \tag{19}$$

If $a = 1$, then

$$L = 5.2441151086... \tag{20}$$

which is related to GAUSS'S CONSTANT M by

$$L = \frac{2\pi}{M}. \tag{21}$$

The quantity $L/2$ or $L/4$ is called the LEMNISCATE CONSTANT and plays a role for the lemniscate analogous to that of π for the CIRCLE.

The AREA of one loop of the lemniscate is

$$A = \tfrac{1}{2}\int r^2\, d\theta = \tfrac{1}{2}a^2\int_{-\pi/4}^{\pi/4}\cos(2\theta)\, d\theta = \tfrac{1}{4}a^2[\sin(2\theta)]_{-\pi/4}^{+\pi/4}$$

$$= \tfrac{1}{2}a^2[\sin(2\theta)]_0^{\pi/4} = \tfrac{1}{2}a^2\left[\sin\left(\tfrac{\pi}{2}\right) - \sin 0\right] = \tfrac{1}{2}a^2. \tag{22}$$

Lemniscate (Mandelbrot Set)

A curve on which points of a MAP z_n (such as the MANDELBROT SET) diverge to a given value $r_{\max}$ at the same rate. A common method of obtaining lemniscates is to define an INTEGER called the COUNT which is the largest n such that $|z_n| < r$ where r is usually taken as $r = 2$. Successive COUNTS then define a series of lemniscates, which are called EQUIPOTENTIAL CURVES by Peitgen and Saupe (1988).

Lemniscate Constant

Let

$$L = \frac{1}{\sqrt{2\pi}}\left[\Gamma\left(\tfrac{1}{4}\right)\right]^2 = 5.2441151086\ldots$$

be the ARC LENGTH of a LEMNISCATE with $a = 1$. Then the lemniscate constant is the quantity $L/2$ (Abramowitz and Stegun 1972), or $L/4 = 1.311028777\ldots$ (Todd 1975, Le Lionnais 1983). Todd (1975) cites T. Schneider (1937) as proving L to be a TRANSCENDENTAL NUMBER.

Lemniscate Function

The lemniscate functions arise in rectifying the ARC LENGTH of the LEMNISCATE. The lemniscate functions were first studied by Jakob Bernoulli and Giulio Fagnano. A historical account is given by Ayoub (1984), and an extensive discussion by Siegel (1969). The lemniscate functions were the first functions defined by inversion of an integral, which was first done by Gauss.

$$L = 2a\int_0^1 (1-t^4)^{-1/2}\,dt. \tag{1}$$

Define the functions

$$\phi(x) \equiv \text{arcsinlemn } x \int_0^x (1-t^4)^{-1/2}\,dt \tag{2}$$

$$\phi'(x) \equiv \text{arccoslemn } x = \int_x^1 (1-t^4)^{-1/2}\,dt, \tag{3}$$

where

$$\varpi \equiv \frac{L}{a}, \tag{4}$$

and write

$$x = \text{sinlemn } \phi \tag{5}$$

$$x = \text{coslemn } \phi'. \tag{6}$$

There is an identity connecting ϕ and ϕ' since

$$\phi(x) + \phi'(x) = \frac{L}{2a} = \tfrac{1}{2}\varpi, \tag{7}$$

so

$$\text{sinlemn } \phi = \text{coslemn}\left(\tfrac{1}{2}\varpi - \phi\right). \tag{8}$$

These functions can be written in terms of JACOBI ELLIPTIC FUNCTIONS,

$$u = \int_0^{\text{sd}(u,\,k)} [(1-k'^2y^2)(1+k^2y^2)]^{-1/2}\,dy. \tag{9}$$

Now, if $k = k' = 1/\sqrt{2}$, then

$$u = \int_0^{\operatorname{sd}(u,\ 1/\sqrt{2})} \left[\left(1-\tfrac{1}{2}y^2\right)\left(1+\tfrac{1}{2}y^2\right)\right]^{-1/2} dy$$

$$= \int_0^{\operatorname{sd}(u,\ 1/\sqrt{2})} \left(1-\tfrac{1}{4}y^4\right)^{-1/2} dy. \quad (10)$$

Let $t \equiv y/\sqrt{2}$ so $dy = \sqrt{2}\, dt$,

$$u = \sqrt{2} \int_0^{\operatorname{sd}(u,\ 1/\sqrt{2})/\sqrt{2}} (1-t^4)^{-1/2}\, dt \quad (11)$$

$$\frac{u}{\sqrt{2}} = \int_0^{\operatorname{sd}(u,\ 1/\sqrt{2})/\sqrt{2}} (1-t^4)^{-1/2}\, dt \quad (12)$$

$$u = \int_0^{\operatorname{sd}(u\sqrt{2},\ 1/\sqrt{2})/\sqrt{2}} (1-t^4)^{-1/2}\, dt \quad (13)$$

and

$$\operatorname{sinlemn}\phi = \frac{1}{\sqrt{2}} \operatorname{sd}\left(\phi\sqrt{2},\ \frac{1}{\sqrt{2}}\right). \quad (14)$$

Similarly,

$$u = \int_{\operatorname{cn}(u,\ k)}^1 (1-t^2)^{-1/2}(k'^2 + k^2t^2)^{-1/2}\, dt$$

$$= \int_{\operatorname{cn}(u,\ 1/\sqrt{2})}^1 (1-t^2)^{-1/2}\left(\tfrac{1}{2}+\tfrac{1}{2}t^2\right)^{-1/2} dt$$

$$= \sqrt{2} \int_{\operatorname{cn}(u,\ 1/\sqrt{2})}^1 (1-t^4)^{-1/2}\, dt \quad (15)$$

$$\frac{u}{\sqrt{2}} = \int_{\operatorname{cn}(u,\ 1/\sqrt{2})}^1 (1-t^4)^{-1/2}\, dt \quad (16)$$

$$u = \int_{\operatorname{cn}(u\sqrt{2},\ 1/\sqrt{2})}^1 (1-t^4)^{-1/2}\, dt, \quad (17)$$

and

$$\operatorname{coslemn}\phi = \operatorname{cn}\left(\phi\sqrt{2},\ \frac{1}{\sqrt{2}}\right). \quad (18)$$

We know

$$\operatorname{coslemn}\left(\tfrac{1}{2}\varpi\right) = \operatorname{cn}\left(\tfrac{1}{2}\varpi\sqrt{2},\ \frac{1}{\sqrt{2}}\right) = 0. \quad (19)$$

But it is true that

$$\operatorname{cn}(K,\ k) = 0, \quad (20)$$

so

$$K\left(\frac{1}{\sqrt{2}}\right) = \tfrac{1}{2}\sqrt{2}\varpi = \frac{1}{\sqrt{2}}\varpi \quad (21)$$

$$\frac{\Gamma^2\left(\frac{1}{4}\right)}{4\sqrt{\pi}} = \frac{1}{\sqrt{2}}\varpi \quad (22)$$

$$L = a\varpi = a\sqrt{2}\,\frac{\Gamma^2\left(\frac{1}{4}\right)}{4\sqrt{\pi}} = \frac{\Gamma^2\left(\frac{1}{4}\right)}{2^{3/2}\sqrt{\pi}}\, a. \quad (23)$$

By expanding $(1-t^4)^{-1/2}$ in a BINOMIAL SERIES and integrating term by term, the arcsinlemn function can be written

$$\phi(x) = \int_0^v \frac{dt}{\sqrt{1-t^4}} = \sum_{n=0}^\infty \frac{\left(\frac{1}{2}\right)_n x^{4n+1}}{n!(4n+1)}, \quad (24)$$

where $(a)_n$ is the RISING FACTORIAL (Berndt 1994). Ramanujan gave the following inversion FORMULA for $\phi(x)$. If

$$\frac{\theta\mu}{\sqrt{2}} = \sum_{n=0}^\infty \frac{\left(\frac{1}{2}\right)_n x^{4n+1}}{n!(4n+1)}, \quad (25)$$

where

$$\mu = \frac{\Gamma^2\left(\frac{1}{4}\right)}{2\pi^{3/2}} \quad (26)$$

is the constant obtained by letting $x = 1$ and $\theta = \pi/2$, and

$$v = 2^{-1/2}\operatorname{sd}(\mu\theta), \quad (27)$$

then

$$\frac{\mu^2}{2x^2} = \csc^2\theta - \frac{1}{\pi} - 8\sum_{n=1}^\infty \frac{n\cos(2n\theta)}{e^{2\pi n}-1} \quad (28)$$

(Berndt 1994). Ramanujan also showed that if $0 < \theta < \pi/2$, then

$$-\frac{\mu}{\sqrt{2}}\sum_{n=0}^\infty \frac{\left(\frac{1}{2}\right)_n v^{4n-1}}{n!(4n-1)}$$

$$= \cot\theta + \frac{\theta}{\pi} + 4\sum_{n=1}^\infty \frac{\sin(2n\theta)}{2^{2\pi n}-1}, \quad (29)$$

$$\ln v + \tfrac{1}{6}\pi - \tfrac{1}{2}\ln 2 + \sum_{n=0}^\infty \frac{\left(\frac{1}{4}\right)_n v^{4n}}{\left(\frac{3}{4}\right)_n 4n}$$

$$= \ln(\sin\theta) + \frac{\theta^2}{2\pi} - 2\sum_{n=1}^\infty \frac{\cos(2n\theta)}{n(e^{2\pi n}-1)}, \quad (30)$$

$$\tfrac{1}{2}\tan^{-1} v = \sum_{n=0}^\infty \frac{\sin[(2n+1)\theta]}{(2n+1)\cosh\left[\frac{1}{2}(2n+1)\pi\right]}, \quad (31)$$

$$\tfrac{1}{4}\cos^{-1}(v^2) = \sum_{n=0}^\infty \frac{(-1)^n\cos[(2n+1)\theta]}{(2n+1)\cosh\left[\frac{1}{2}(2n+1)\pi\right]}, \quad (32)$$

and

$$\frac{\sqrt{2}}{4\mu}\sum_{n=0}^{\infty}\frac{2^{2n}(n!)^2}{(2n+1)!(4n+3)}v^{4n+3}$$
$$=\frac{\pi\theta}{8}-\sum_{n=0}^{\infty}\frac{(-1)^n\sin[(2n+1)\theta]}{(2n+1)^2\cosh\left[\frac{1}{2}(2n+1)\pi\right]} \tag{33}$$

(Berndt 1994).

A generalized version of the lemniscate function can be defined by letting $0 \leq \theta \leq \pi/2$ and $0 \leq v \leq 1$. Write

$$\tfrac{2}{3}\,\theta\mu = \int_0^v \frac{dt}{\sqrt{1-t^6}}, \tag{34}$$

where μ is the constant obtained by setting $\theta = \pi/2$ and $v = 1$. Then

$$\mu = \frac{\sqrt{\pi}}{\Gamma\left(\frac{2}{3}\right)\Gamma\left(\frac{5}{6}\right)}, \tag{35}$$

and Ramanujan showed

$$\frac{4\mu^2}{9v^2} = \csc^2\theta - \frac{2}{\pi\sqrt{3}} + 8\sum_{n=1}^{\infty}\frac{(-1)^{n-1}n\cos(2n\theta)}{e^{\pi n\sqrt{3}}-(-1)^n} \tag{36}$$

(Berndt 1994).

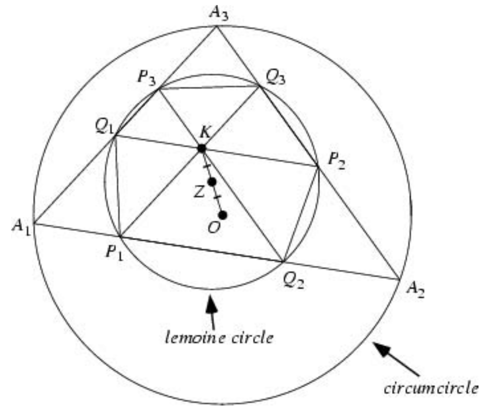
Lemniscate of Bernoulli

Lemniscate



Lemniscate of Gerono

Eight Curve

Lemoine Axis

Lemoine Line

Lemoine Circle

Draw lines P_1Q_1, P_2Q_2, and P_3Q_3 through the symmedian point K and parallel to the sides of the triangle $\Delta A_1A_2A_3$. The points where the parallel lines intersect the sides of $\Delta A_1A_2A_3$ then lie on a circle known as the Lemoine circle, or sometimes the triplicate-ratio circle (Tucker 1883). This circle has center at the midpoint Z of OK, where O is the circumcenter, and radius

$$\tfrac{1}{2}\sqrt{R^2+r_c^2} = \tfrac{1}{2}R\sec\omega,$$

where R is the circumradius, r_c is radius of the cosine circle, and ω is the Brocard angle of the original triangle (Johnson 1929, p. 274). The Lemoine circle and Brocard circle are concentric, and the triangles ΔQ_1P_3K, ΔKQ_3P_2, and ΔP_1KQ_2 are similar to $\Delta A_1A_3A_2$ (Tucker 1883).

The Lemoine circle divides any side into segments proportional to the squares of the sides

$$\overline{A_2P_2} : \overline{P_2Q_3} : \overline{Q_3A_3} = a_3^2 : a_1^2 : a_2^2$$

Furthermore, the chords cut from the sides by the Lemoine circle are proportional to the squares of the sides.

The cosine circle is sometimes called the second Lemoine circle. The Lemoine circle is a special case of a Tucker circle.

Lemoine Hexagon

The closed self-intersecting cyclic hexagon formed by joining the adjacent PARALLELS in the construction of the LEMOINE CIRCLE. The sides of this hexagon have the property that, in addition to $Q_1P_2 \| A_1A_2$, $Q_2P_3 \| A_2A_3$, and $Q_3P_2 \| A_1A_3$, the remaining sides Q_1P_1, Q_2P_2, and Q_3P_3 are ANTIPARALLEL to A_2A_3, A_1A_3, and A_1A_2, respectively. The Lemoine hexagon is a special case of a TUCKER HEXAGON.

See also COSINE HEXAGON, LEMOINE CIRCLE, TUCKER HEXAGON

Lemoine Line

The Lemoine line, also called the LEMOINE AXIS, is the perspectivity axis of a TRIANGLE and its TANGENTIAL TRIANGLE, and also the TRILINEAR POLAR of the CENTROID of the triangle vertices. It is also the POLAR of K with regard to its CIRCUMCIRCLE, and is PERPENDICULAR to the BROCARD AXIS.

The centers of the APOLLONIUS CIRCLES L_1, L_2, and L_3 are COLLINEAR on the LEMOINE LINE. This line is PERPENDICULAR to the BROCARD AXIS OK and is the RADICAL AXIS of the CIRCUMCIRCLE and the BROCARD CIRCLE. It has equation

$$\frac{\alpha}{a}+\frac{\beta}{b}+\frac{\gamma}{c}$$

in terms of TRILINEAR COORDINATES (Oldknow 1996).

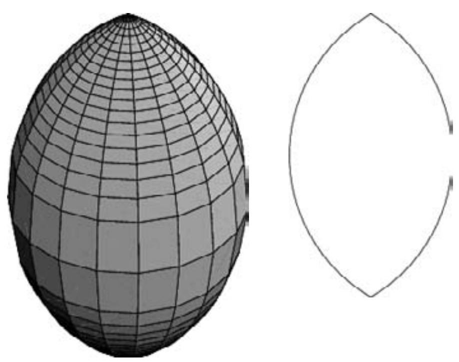
Lemoine Point



SYMMEDIAN POINT

Lemoine's Problem

Given the vertices of the three EQUILATERAL TRIANGLES placed on the sides of a TRIANGLE T, construct T. The solution can be given using KIEPERT'S HYPERBOLA.

See also KIEPERT'S HYPERBOLA

Lemon

A SURFACE OF REVOLUTION defined by Kepler. It consists of less than half of a circular ARC rotated about an axis passing through the endpoints of the ARC. The equations of the upper and lower boundaries in the xz plane are

$$z_{\pm} = \pm\sqrt{R^2-(x+r)^2}$$

for $R > r$ and $x \in [-(R-r), R-r]$. The CROSS SECTION of a lemon is a LENS. The lemon is the inside surface of a SPINDLE TORUS. The American football is shaped like a lemon.

See also APPLE, LENS, OVAL, PROLATE SPHEROID, SPINDLE TORUS

Length (Curve)

Let $\gamma(t)$ be a smooth curve in a MANIFOLD M from x to y with $\gamma(0)=x$ and $\gamma(1)=y$. Then $\gamma'(t)\in T_{\gamma(t)}$ where T_x is the TANGENT SPACE of M at x. The length of γ with respect to the Riemannian structure is given by

$$\int_0^1 \|\gamma'(t)\|_{\gamma(t)}\, dt.$$

See also ARC LENGTH, DISTANCE

Length (Number)

The length of a number n in base b is the number of DIGITS in the base-b numeral for n, given by the formula

$$L(n,\ b)=\lfloor \log_b(n)\rfloor+1,$$

where $\lfloor x\rfloor$ is the FLOOR FUNCTION.

The MULTIPLICATIVE PERSISTENCE of an n-DIGIT is sometimes also called its length.

See also CONCATENATION, DIGIT, FIGURES, MULTIPLICATIVE PERSISTENCE

Length (Partial Order)

For a PARTIAL ORDER, the size of the longest CHAIN is called the length.

See also WIDTH (PARTIAL ORDER)

Length (Size)

The longest dimension of a 3-D object.

See also HEIGHT, WIDTH (SIZE)

Length Distribution Function

A function giving the distribution of the interpoint distances of a curve. It is defined by

$$p(r)=\frac{1}{N}\sum_{ij}\delta_{rij}=r.$$

See also RADIUS OF GYRATION

Length-Preserving Transformation

ISOMETRY

Lengyel's Constant

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Let L denote the partition lattice of the SET $\{1,\ 2,\ \ldots,\ n\}$. The MAXIMUM element of L is

$$M=\{\{1,2,\ \ldots,\ n\}\} \tag{1}$$

and the MINIMUM element is

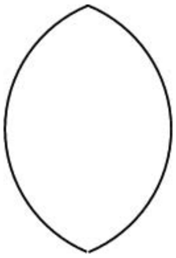
$$m=\{\{1\},\{2\},\ \ldots,\ \{n\}\}. \tag{2}$$

Let Z_n denote the number of chains of any length in L containing both M and m. Then Z_n satisfies the RECURRENCE RELATION

$$Z_n=\sum_{k=1}^{n-1} s(n,\ k)Z_k, \tag{3}$$

where $s(n,\ k)$ is a STIRLING NUMBER OF THE SECOND KIND. Lengyel (1984) proved that the QUOTIENT

$$r(n)=\frac{Z_n}{(n!)^2(2\ln 2)^{-n}n^{1-(\ln 2)/3}} \tag{4}$$



is bounded between two constants as $n\to\infty$, and Flajolet and Salvy (1990) improved the result of Babai and Lengyel (1992) to show that

$$\Lambda\equiv\lim_{n\to\infty} r(n)=1.0986858055\ldots. \tag{5}$$

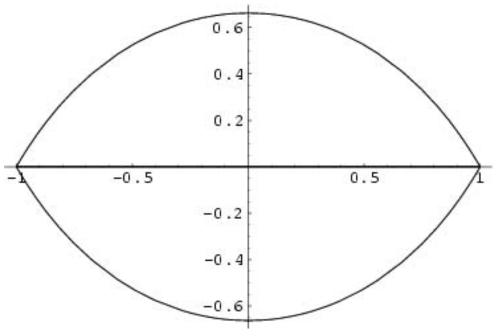
Lens

A figure composed of two equal and symmetrically placed circular ARCS. It is also known as the FISH BLADDER (Pedoe 1995, p. xii) or VESICA PISCIS. The latter term is often used for the particular lens formed by the intersection of two unit CIRCLES whose

centers are offset by a unit distance (Rawles 1997). In this case, the height of the lens is given by letting $d = r = R = 1$ in the equation for a CIRCLE-CIRCLE INTERSECTION

$$a = \frac{1}{d}\sqrt{4d^2R^2 - (d^2 - r^2 + R^2)^2}, \tag{1}$$



giving $a = \sqrt{3}$. The AREA of the VESICA PISCIS is given by plugging $d = R$ into the CIRCLE-CIRCLE INTERSECTION area equation with $r = R$,

$$A = 2R^2 \cos^{-1}\left(\frac{d}{2R}\right) - \tfrac{1}{2} d\sqrt{4R^2 - d^2}, \tag{2}$$

giving

$$A = \tfrac{1}{6}\left(4\pi - 3\sqrt{3}\right) \approx 1.22837. \tag{3}$$

Renaissance artists frequently surrounded images of Jesus with the vesica piscis (Rawles 1997). An asymmetrical lens is produced by a CIRCLE-CIRCLE INTERSECTION for unequal CIRCLES.

A lens-shaped region also arises in the study of BESSEL FUNCTIONS. Letting $z = e^{i\theta}$, the inequality

$$\left|\frac{z \exp(1 - z^2)}{1 + \sqrt{1 - z^2}}\right| \leq 1$$

holds in the region illustrated above. This region can be parameterized in terms of a variable u as

$$r^2 = \frac{2u}{\sinh(2u)} \tag{4}$$

$$\sin^2 \theta = \sinh u(u \cosh u - \sinh u). \tag{5}$$

As u increases from u to its maximum value of 1.19967874... (the root of $\sinh u(u \cosh u - \sinh u) = 0$), r decreases from 1 to 0.6627434... (Plummer 1960, p. 47; Watson 1966, p. 270). This curve is very important in the theory of KAPTEYN SERIES.

LerchPhi

LERCH TRANSCENDENT

Lerch's Theorem

If there are two functions $F_1(t)$ and $F_2(t)$ with the same integral transform

$$\mathscr{T}[F_1(t)] = \mathscr{T}[F_2(t)] \equiv f(s), \tag{1}$$

then a NULL FUNCTION can be defined by

$$\delta_0(t) \equiv F_1(t) - F_2(t) \tag{2}$$

so that the integral

$$\int_0^a \delta_0(t)\, dt = 0 \tag{3}$$

vanishes for all $a > 0$.

See also NULL FUNCTION

Lerch Transcendent

A generalization of the HURWITZ ZETA FUNCTION and POLYLOGARITHM function. Many sums of reciprocal POWERS can be expressed in terms of it. It is defined by

$$\Phi(z,\ s,\ a) \equiv \sum_{k=0}^{\infty} \frac{z^k}{(a+k)^s}, \tag{1}$$

where any term with $a + k = 0$ is excluded. The Lerch transcendent is given by the *Mathematica* command LerchPhi[z, s, a].

The Lerch transcendent can be used to express the DIRICHLET BETA FUNCTION

$$\beta(s) \equiv \sum_{k=0}^{\infty} (-1)^k (2k+1)^{-s} 2^{-s} \Phi\left(-1,\ s,\ \tfrac{1}{2}\right), \tag{2}$$

the integral of the FERMI-DIRAC DISTRIBUTION

$$\int_0^\infty \frac{k^s}{e^{k-\mu}+1}\, dk = e^\mu \Gamma(s+1) \Phi(-e^\mu,\ s+1, 1), \tag{3}$$

where $\Gamma(z)$ is the GAMMA FUNCTION, and to evaluate the DIRICHLET L-SERIES.

Level Surface

A LEVEL SET in 3-D.

Levenberg-Marquardt Method

Levenberg-Marquardt is a popular alternative to the Gauss-Newton method of finding the minimum of a function $F(x)$ that is a sum of squares of nonlinear functions,

$$F(x) = \frac{1}{2} \sum_{i=1}^{m} [f_i(x)]^2.$$

Let the JACOBIAN of $f_i(x)$ be denoted $\mathsf{J}_i(x)$, then the Levenberg-Marquardt method searches in the direction given by the solution $\mathbf{p}$ to the equations

$$(\mathsf{J}_k^{\mathrm{T}} \mathsf{J}) + \lambda_k \mathsf{I})p_k = -\mathsf{J}_k^{\mathrm{T}} f_k,$$

where λ_k are nonnegative scalars and I is the IDENTITY MATRIX. The method has the nice property that, for some scalar Δ related to λ_k, the vector p_k is the solution of the constrained subproblem of minimizing $\|J_k p + f_k\|_2^2/2$ subject to $\|p\|_2 \leq \Delta$ (Gill *et al.* 1981, p. 136).

The method is used by the *Mathematica* 4.0 command FindMinimum[f, {x, $x0$}] when given the Method- > LevenbergMarquardt option.

Levi-Civita Connection

On a RIEMANNIAN MANIFOLD M, there is a canonical CONNECTION called the Levi-Civita connection (pronounced le-ve shi-vit-), sometimes also known as the Riemannian connection or COVARIANT DERIVATIVE. As a CONNECTION on the TANGENT BUNDLE, it provides a well-defined method for differentiating VECTOR FIELDS, forms, or any other kind of TENSOR. The theorem asserting the existence of the Levi-Civita connection, which is the unique TORSION-free CONNECTION ∇ on the TANGENT BUNDLE TM compatible with the metric, is called the FUNDAMENTAL THEOREM OF RIEMANNIAN GEOMETRY.

These properties can be described as follows. Let X, Y, and Z be any VECTOR FIELDS, and $\langle , \rangle$ denote the METRIC. Recall that vector fields act as DERIVATIONS on the ring of smooth functions by the DIRECTIONAL DERIVATIVE, and that this action extends to an action on vector fields. The notation $[X, Y]$ is the COMMUTATOR of vector fields, $XY - YX$. The Levi-Civita connection is torsion-free, meaning

$$\nabla_X \nabla_Y Z - \nabla_Y \nabla_X Z = \nabla_{[X,\ Y]} Z, \qquad (1)$$

and is compatible with the metric

$$X(Y,\ Z) = \langle \nabla_X Y,\ Z \rangle + \langle Y,\ \nabla_X Z \rangle. \qquad (2)$$

In coordinates, the Levi-Civita connection can be described using the CHRISTOFFEL SYMBOLS OF THE SECOND KIND $\Gamma^k_{i,\ j}$. In particular, if $e_i = \partial / \partial x_i$, then

$$\Gamma^k_{i,\ j} = \langle \nabla_{e_i} e_j,\ e_k \rangle, \qquad (3)$$

or in other words,

$$\nabla_{e_i} e_j = \sum_k \Gamma^k_{i,\ j} e_k. \qquad (4)$$

As a CONNECTION on the TANGENT BUNDLE TM, it induces a connection on the DUAL BUNDLE T^*M and on all their TENSOR PRODUCTS $TM^k \otimes TM^{*l}$. Also, given a SUBMANIFOLD N it restricts to TN to give the Levi-Civita connection from the restriction of the metric to N.

The Levi-Civita connection can be used to describe many intrinsic geometric objects. For instance, a path $c : \mathbb{R} \to M$ is a geodesic IFF $\nabla_{\dot{c}(t)} \dot{c}(t) = 0$ where $\dot{c}$ is the path's TANGENT VECTOR. On a more general path c, the equation $\nabla_{\dot{c}(t)} v(t) = 0$ defines PARALLEL TRANSPORT for a VECTOR FIELD v along c. The SECOND FUNDAMENTAL FORM **II** of a submanifold N is given by $\pi_Q \circ \nabla_{TN}$ where TN is the TANGENT BUNDLE of N and π_Q is projection onto the NORMAL BUNDLE Q. The CURVATURE of M is given by $\nabla \circ \nabla$.

Levi Graph

The unique 8-CAGE GRAPH (right figure) consisting of the union of the two leftmost subgraphs illustrated above. It has 45 nodes, 15 edges, and all nodes have degree 3. The Levi graph is a GENERALIZED POLYGON which is the point/line INCIDENCE GRAPH of the generalized quadrangle W_2. The graph is a 4-arc transitive cubic graph, was first discovered by Tutte (1947), and is also called the Tutte-Coxeter graph

(Bondy and Murty 1976, p. 237).

An alternative embedding is illustrated above.

Lévy Constant

Let p_n/q_n be the nth CONVERGENT of a REAL NUMBER x. Then almost all REAL NUMBERS satisfy

$$L \equiv \lim_{n \to \infty} (q_n)^{1/n} = e^{\pi^2/(12 \ln 2)} = 3.27582291872\ldots$$

Lévy Distribution

$$\mathcal{F}[P_N(k)] = \mathcal{F}[\exp(-N|k|^\beta)],$$

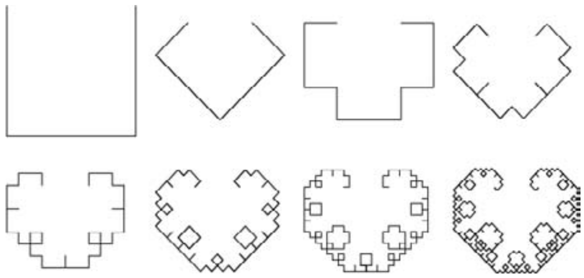
where $\mathcal{F}$ is the FOURIER TRANSFORM of the probability $P_N(k)$ for N-step addition of random variables. Lévy showed that $\beta \in (0, 2)$ for $P(x)$ to be NONNEGATIVE. The Lévy distribution has infinite variance and sometimes infinite mean. The case $\beta = 1$ gives a CAUCHY DISTRIBUTION, while $\beta = 2$ gives a GAUSSIAN DISTRIBUTION.

See also CAUCHY DISTRIBUTION, GAUSSIAN DISTRIBUTION, LÉVY FLIGHT

Lévy Dragon

LÉVY FRACTAL

Lévy Flight



RANDOM WALK trajectories which are composed of self-similar jumps. They are described by the LÉVY DISTRIBUTION.

Lexicographic Order

An ordering for the Cartesian product $\times$ of any two sets A and B with order relations $<A$ and $<B$, respectively, such that if $(a_1,\ b_1)$ and $(a_2,\ b_2)$ both belong to $A \times B$, then $(a_1,\ b_1) < (a_2,\ b_2)$ IFF either

1. $a_1 < Aa_2$, or
2. $a_1 = a_2$ and $b_1 < Bb_2$.

The lexicographic order can be readily extended to cartesian products of arbitrary length by recursively applying this definition, i.e., by observing that $A \times B \times C = A \times (B \times C)$.

When applied to PERMUTATIONS, lexicographic order is increasing numerical order (or equivalently, alphabetic order for lists of symbols; Skiena 1990, p. 4). For example, the PERMUTATIONS of {1, 2, 3} in lexicographic order are 123, 132, 213, 231, 312, and 321.

When applied to subsets, two subsets are ordered by their smallest elements (Skiena 1990, p. 44). For example, the subsets of {1, 2, 3} in lexicographic order are {}, {1}, {1, 2}, {1, 2, 3}, {1, 3}, {2}, {2, 3}, {3}.

Lexicographic order is sometimes called dictionary order.

Lexis Ratio

$$L \equiv \frac{\sigma}{\sigma_B},$$

where σ is the VARIANCE in a set of s LEXIS TRIALS and σ_B is the VARIANCE assuming BERNOULLI TRIALS. If $L < 1$, the trials are said to be SUBNORMAL, and if $L > 1$, the trials are said to be SUPERNORMAL.

See also BERNOULLI TRIAL, LEXIS TRIALS, SUBNORMAL, SUPERNORMAL

Lexis Trials

n sets of s trials each, with the probability of success p constant in each set.

$$\text{var}\left(\frac{x}{n}\right) = spq + s(s-1)\sigma_p^2,$$

where σ_p^2 is the VARIANCE of p_i.

See also BERNOULLI TRIAL, LEXIS RATIO

L-Function

ARTIN L-FUNCTION, DIRICHLET L-SERIES, EULER L-FUNCTION, HECKE L-FUNCTION

Lg

The LOGARITHM to BASE 2 is denoted lg, i.e.,

$$\lg x \equiv \log_2 x.$$

Care is needed in interpreting this symbol, however, since Russian literature uses $\lg x$ to denote the base-10 logarithm denoted in this work by $\log x$.

L'Hospital's Cubic

TSCHIRNHAUSEN CUBIC

L'Hospital's Rule

Let lim stand for the LIMIT $\lim_{x\to c}$, $\lim_{x\to c^-}$, $\lim_{x\to c^+}$, $\lim_{x\to\infty}$, or $\lim_{x\to-\infty}$, and suppose that $\lim f(x)$ and $\lim g(x)$ are both ZERO or are both $\pm\infty$. If

$$\lim \frac{f'(x)}{g'(x)}$$

has a finite value or if the LIMIT is $\pm\infty$, then

$$\lim \frac{f(x)}{g(x)} = \lim \frac{f'(x)}{g'(x)}.$$

L'Hospital's rule occasionally fails to yield useful results, as in the case of the function $\lim_{u\to\infty} u(u^2+1)^{-1/2}$. Repeatedly applying the rule in this case gives expressions which oscillate and never converge,

$$\lim_{u\to\infty} \frac{u}{(u^2+1)^{1/2}} = \lim_{u\to\infty} \frac{1}{u(u^2+1)^{-1/2}}$$
$$= \lim_{u\to\infty} \frac{(u^2+1)^{1/2}}{u} = \lim_{u\to\infty} \frac{u(u^2+1)^{-1/2}}{1}$$
$$= \lim_{u\to\infty} \frac{u}{(u^2+1)^{1/2}}.$$

(The actual LIMIT is 1.)

Liar's Paradox

The paradox of a man who states "I am lying." If he *is* lying, then he is telling the truth, and vice versa. Another version of this paradox is the EPIMENIDES PARADOX. Such paradoxes are often analyzed by creating so-called "metalanguages" to separate statements into different levels on which truth and falsity can be assessed independently. For example, Bertrand Russell noted that, "The man who says, 'I am telling a lie of order n' *is* telling a lie, but a lie of order $n+1$" (Gardner 1984, p. 222).

Lichnerowicz Conditions

Second and higher derivatives of the METRIC TENSOR g_{ab} need not be continuous across a surface of discontinuity, but g_{ab} and $g_{ab,\,c}$ must be continuous across it.

Lichnerowicz Formula

$$D^*D\psi = \nabla^*\nabla\psi + \tfrac{1}{4}R\psi - \tfrac{1}{2}F_L^+(\psi),$$

where D is the Dirac operator $D : \Gamma(W^+) \to \Gamma(W^-)$, ∇ is the COVARIANT DERIVATIVE on SPINORS, R is the CURVATURE SCALAR, and F_L^+ is the self-dual part of the curvature of L.

Lichtenfels Minimal Surface

A MINIMAL SURFACE that contains LEMNISCATES as geodesics which is given by the parametric equations

$$x = \Re\left[\sqrt{2}\cos\left(\tfrac{1}{2}\zeta\right)\sqrt{\cos\left(\tfrac{2}{3}\zeta\right)}\right] \tag{1}$$

$$y = \Re\left[-\sqrt{2}\sin\left(\tfrac{1}{3}\zeta\right)\sqrt{\cos\left(\tfrac{2}{3}\zeta\right)}\right] \tag{2}$$

$$z = \Re\left[-\tfrac{1}{3}\sqrt{2}i\int_0^\zeta \frac{d\zeta}{\sqrt{\cos\left(\tfrac{2}{3}\zeta\right)}}\right] \tag{3}$$

$$= \Re\left[-i\sqrt{2}\,F\left(\sqrt{\tfrac{1}{3}}\zeta,\ 2\right)\right], \tag{4}$$

where $F(x, x)$ is an incomplete ELLIPTIC INTEGRAL OF THE FIRST KIND and $\zeta = u + iv$ is a COMPLEX NUMBER. A given LEMNISCATE is the intersection of the surface with the xy-plane. The surface is periodic in the direction of the axis with period

$$\omega = 2\int_0^1 \frac{dt}{\sqrt{1-t^2}\sqrt{1-\frac{1}{2}t^2}} = 2K\left(\frac{1}{2}\right), \tag{5}$$

where $K(x)$ is a complete ELLIPTIC INTEGRAL OF THE FIRST KIND.

Lie Algebra

A NONASSOCIATIVE ALGEBRA obeyed by objects such as the LIE BRACKET and POISSON BRACKET. Elements f, g, and h of a Lie algebra satisfy

$$[f, f] = 0 \tag{1}$$

$$[f+g, h] = [f, h] + [g, h], \tag{2}$$

and

$$[f, [g, h]] + [g, [h, f]] + [h, [f, g]] = 0 \tag{3}$$

(the JACOBI IDENTITY). The relation $[f, f] = 0$ implies

$$[f, g] = -[g, f]. \tag{4}$$

For characteristic not equal to two, these two relations are equivalent.

The binary operation of a Lie algebra is the bracket

$$[fg, h] = f[g, h] + g[f, h]. \tag{5}$$

An ASSOCIATIVE ALGEBRA A with associative product xy can be made into a Lie algebra A^- by the Lie product

$$[x, y] = xy - yx. \tag{6}$$

Every Lie algebra L is isomorphic to a SUBALGEBRA of some A^- where the associative algebra A may be taken to be the linear operators over a VECTOR SPACE V (the POINCARÉ-BIRKHOFF-WITT THEOREM; Jacobson 1979, pp. 159–60). If L is finite dimensional, then V can be taken to be finite dimensional (ADO'S THEOREM for characteristic $p = 0$; IWASAWA'S THEOREM for characteristic $p \neq 0$).

The classification of finite dimensional simple Lie algebras over an algebraically closed field of characteristic 0 can be accomplished by (1) determining matrices called CARTAN MATRICES corresponding to indecomposable simple systems of roots and (2) determining the simple algebras associated with these matrices (Jacobson 1979, p. 128). This is one of the major results in Lie algebra theory, and is frequently accomplished with the aid of diagrams called DYNKIN DIAGRAMS.

See also ADO'S THEOREM, DERIVATION ALGEBRA, DYNKIN DIAGRAM, JACOBI IDENTITIES, LIE ALGEBROID, LIE BRACKET, IWASAWA'S THEOREM, POINCARÉ-BIRKHOFF-WITT THEOREM, POISSON BRACKET, REDUCED ROOT SYSTEM, ROOT SYSTEM, WEYL GROUP

Lie Bracket

The commutation operation

$$[a, b] = ab - ba$$

corresponding to the LIE PRODUCT.

See also LAGRANGE BRACKET, POISSON BRACKET

Lie Commutator

LIE PRODUCT

Lie Derivative

The Lie derivative of TENSOR T_{ab} with respect to the VECTOR FIELD X is defined by

$$\mathscr{L}_X T_{ab} \equiv \lim_{\delta x \to 0} \frac{T'_{ab}(x') - T_{ab}(x)}{\delta x}. \quad (1)$$

Explicitly, it is given by

$$\mathscr{L}_X T_{ab} = T_{ab} X^d_{,b} + T_{bd} X^d_{,a} + T_{ab,\ e} X^e, \quad (2)$$

where $X_{,a}$ is a COMMA DERIVATIVE. The Lie derivative of a METRIC TENSOR g_{ab} with respect to the VECTOR FIELD X is given by

$$\mathscr{L}_X g_{ab} = X_{a;\ b} + X_{b;\ a} = 2X_{(a;\ b)}, \quad (3)$$

where $X_{(a,\ b)}$ denotes the SYMMETRIC TENSOR part and $X_{a;\ b}$ is a COVARIANT DERIVATIVE.

See also COVARIANT DERIVATIVE, KILLING'S EQUATION, KILLING VECTORS, LIE DERIVATIVE (SPINOR)

Lie Derivative (Spinor)

The Lie derivative of a SPINOR ψ is defined by

$$\mathscr{L}_X \psi(x) = \lim_{t \to 0} \frac{\tilde{\psi}_t(x) - \psi(x)}{t},$$

where $\tilde{\psi}_t$ is the image of ψ by a one-parameter group of isometries with X its generator. For a VECTOR FIELD X^a and a COVARIANT DERIVATIVE ∇_a, the Lie derivative of ψ is given explicitly by

$$\mathscr{L}_X \psi = X^a \nabla_a \psi - \tfrac{1}{8}(\nabla_a X_b - \nabla_b X_a)\gamma^a \gamma^b \psi,$$

where γ^a and γ^b are DIRAC MATRICES (Choquet-Bruhat and DeWitt-Morette 2000).

See also COVARIANT DERIVATIVE, DIRAC MATRICES, LIE DERIVATIVE, SPINOR

Lie Group

A Lie group is a DIFFERENTIABLE MANIFOLD obeying the group properties and that satisfies the additional condition that the group operations are continuous.

The simplest examples of Lie groups are one-dimensional. Under addition, the REAL LINE is a Lie group. After picking a specific point to be the IDENTITY ELEMENT, the CIRCLE is also a Lie group. Another point on the circle at angle θ from the identity then acts by rotating the circle by the angle θ. In general, a Lie group may have a more complicated group structure, such as the ORTHOGONAL GROUP $O(n)$ (i.e., the $n \times n$ orthogonal matrices), or the GENERAL LINEAR GROUP $GL(n)$ (i.e., the $n \times n$ invertible matrices). The LORENTZ GROUP is also a Lie group.

The TANGENT SPACE at the identity of a Lie group always has the structure of a LIE ALGEBRA, and this LIE ALGEBRA determines the local structure of the Lie group via the EXPONENTIAL MAP. For example, the function e^{it} gives the EXPONENTIAL MAP from the circle's tangent space (i.e., the reals), to the circle, thought of as a the UNIT CIRCLE in $\mathbb{C}$. A more difficult example is the exponential map e^{A} from SKEW SYMMETRIC $n \times n$ matrices to the SPECIAL ORTHOGONAL GROUP $SO(n)$, the subset of $O(n)$ with determinant 1.

The topology of a Lie group is fairly restricted. For example, there always exists a nonvanishing VECTOR FIELD. This structure has allowed complete classification of the finite dimensional SEMISIMPLE LIE GROUPS and their representations.

Lie Groupoid

A GROUPOID G over B for which G and B are differentiable manifolds and α, β, and multiplication are differentiable maps. Furthermore, the derivatives of α and β are required to have maximal RANK everywhere. Here, α and β are maps from G onto $\mathbb{R}^2$ with $\alpha : (x,\ \gamma,\ y) \mapsto z$ and $\beta : (x,\ \gamma,\ y) \mapsto y$

Life

The most well-known CELLULAR AUTOMATON, invented by John Conway and popularized in Martin Gardner's *Scientific American* column starting in October 1970. The game was originally played (i.e., successive generations were produced) by hand with counters, but implementation on a computer greatly increased the ease of exploring patterns.

The Life CELLULAR AUTOMATON is run by placing a number of filled cells on a 2-D grid. Each generation then switches cells on or off depending on the state of the cells that surround it. The rules are defined as follows. All eight of the cells surrounding the current one are checked to see if they are on or not. Any cells that are on are counted, and this count is then used to determine what will happen to the current cell.

1. Death: if the count is less than 2 or greater than 3, the current cell is switched off.
2. Survival: if (a) the count is exactly 2, or (b) the count is exactly 3 and the current cell is on, the current cell is left unchanged.
3. Birth: if the current cell is off and the count is exactly 3, the current cell is switched on.

Hensel gives a JAVA APPLET implementing the Game of Life on his web page. Weisstein gives an extensive alphabetical tabulation of life forms and terms.

A pattern which does not change from one generation to the next is known as a still life , and is said to have period 1. Conway originally believed that no pattern could produce an infinite number of cells, and offered a $50 prize to anyone who could find a counterexample before the end of 1970 (Gardner 1983, p. 216). Many counterexamples were subsequently found, including guns and puffer trains.

A Life pattern which has no father pattern is known as a Garden of Eden (for obvious biblical reasons). The first such pattern was not found until 1971, and at least 3 are now known. It is not, however, known if a pattern exists which has a father pattern , but no grandfather pattern (Gardner 1983, p. 249).

Rather surprisingly, Gosper and J. H. Conway independently showed that Life can be used to generate a UNIVERSAL TURING MACHINE (Berlekamp *et al.* 1982, Gardner 1983, pp. 250–53).

Similar CELLULAR AUTOMATON games with different rules are HEXLIFE and HIGHLIFE. HASHLIFE is a life ALGORITHM that achieves remarkable speed by storing subpatterns in a hash table, and using them to skip forward, sometimes thousands of generations at a time.

Life Expectancy

An l_x table is a tabulation of numbers which is used to calculate life expectancies.

x	n_x	d_x	l_x	q_x	L_x	T_x	e_x
0	1000	200	1.00	0.20	0.90	2.70	2.70
1	800	100	0.80	0.12	0.75	1.80	2.25
2	700	200	0.70	0.29	0.60	1.05	1.50

3	500	300	0.50	0.60	0.35	0.45	0.90
4	200	200	0.20	1.00	0.10	0.10	0.50
5	0	0	0.00	–	0.00	0.00	–
Σ		1000	2.70				

x: Age category ($x = 0, 1, ..., k$). These values can be in any convenient units, but must be chosen so that no observed lifespan extends past category $k-1$.

n_x : Census size, defined as the number of individuals in the study population who survive to the beginning of age category x. Therefore, $n_0 = N$ (the total population size) and $n_k = 0$.

$d_x : n_x - n_{x+1}$; $\Sigma_{i=0}^{k} d_i = n_0$. Crude death rate, which measures the number of individuals who die within age category x.

$l_x : = n_x/n_0$. Survivorship, which measures the *proportion* of individuals who survive to the beginning of age category x.

$q_x : = dx/n_x$; $q_{k-1} = 1$. Proportional death rate, or "risk," which measures the proportion of individuals surviving to the beginning of age category x who die within that category.

$L_x : = (l_x + l_{x+1})/2$. Midpoint survivorship, which measures the proportion of individuals surviving to the *midpoint* of age category x. Note that the simple averaging formula must be replaced by a more complicated expression if survivorship is nonlinear within age categories. The sum $\Sigma_{i=0}^{k} L_x$ gives the total number of age categories lived by the entire study population.

$T_x : T_{x-1} - L_{x-1}$; $T_0 = \Sigma_{i=0}^{k} L_x$. Measures the total number of age categories left to be lived by all individuals who survive to the beginning of age category x.

$e_x : = T_x/l_x$; $e_{k-1} = 1/2$. Life expectancy, which is the mean number of age categories remaining until death for individuals surviving to the beginning of age category x.

For all x, $e_{x+1} + 1 > e_x$. This means that the total expected lifespan increases monotonically. For instance, in the table above, the one-year-olds have an average age at death of $2.25 + 1 = 3.25$, compared to 2.70 for newborns. In effect, the age of death of older individuals is a distribution conditioned on the fact that they have survived to their present age.

It is common to study survivorship as a semilog plot of l_x vs. x, known as a SURVIVORSHIP CURVE. A so-called $l_x m_x$ table can be used to calculate the mean generation time of a population. Two $l_x m_x$ tables are illustrated below.

Population 1

x	l_x	m_x	$l_x m_x$	$x l_x m_x$
0	1.00	0.00	0.00	0.00
1	0.70	0.50	0.35	0.35
2	0.50	1.50	0.75	1.50
3	0.20	0.00	0.00	0.00
4	0.00	0.00	0.00	0.00
			$R_0 = 1.10$	$\Sigma = 1.85$

$$T = \frac{\sum x l_x m_x}{\sum l_x m_x} = \frac{1.85}{1.10} = 1.68$$

$$r = \frac{\ln R_0}{T} = \frac{\ln 1.10}{1.68} = 0.057.$$

Population 2

x	l_x	m_x	$l_x m_x$	$x l_x m_x$
0	1.00	0.00	0.00	0.00
1	0.70	0.00	0.00	0.00
2	0.50	2.00	1.00	2.00
3	0.20	0.50	0.10	0.30
4	0.00	0.00	0.00	0.00
			$R_0 = 1.10$	$\Sigma = 2.30$

$$T = \frac{\sum x l_x m_x}{\sum l_x m_x} = \frac{2.30}{1.10} = 2.09$$

$$r = \frac{\ln R_0}{T} = \frac{\ln 1.10}{2.09} = 0.046.$$

x: Age category ($x = 0, 1, ..., k$). These values can be in any convenient units, but must be chosen so that no observed lifespan extends past category $k-1$ (as in an l_x table).

$l_x : = n_x/n_0$. Survivorship, which measures the *proportion* of individuals who survive to the beginning of age category x (as in an l_x table).

m_x : The average number of offspring produced by an individual in age category x *while in that age category*. $\Sigma_{i=0}^{k} m_x$ therefore represents the average lifetime number of offspring produced by an individual of maximum lifespan.

$l_x m_x$: The average number of offspring produced by an individual within age category x weighted by the probability of surviving to the beginning of that age category. $\Sigma_{i=0}^{k} l_x m_x$ therefore represents

the average lifetime number of offspring produced by a member of the study population. It is called the net reproductive rate per generation and is often denoted R_0.
$xl_x m_x$: A column weighting the offspring counted in the previous column by their parents' age when they were born. Therefore, the ratio $T = \Sigma(xl_x m_x)/\Sigma(l_x m_x)$ is the mean generation time of the population.

The MALTHUSIAN PARAMETER r measures the reproductive rate per unit time and can be calculated as $r = (\ln R_0)/T$. For an exponentially increasing population, the population size $N(t)$ at time t is then given by

$$N(t) = N_0 e^{rt}.$$

In the above two tables, the populations have identical reproductive rates of $R_0 = 1.10$. However, the shift toward later reproduction in population 2 increases the generation time, thus slowing the rate of POPULATION GROWTH. Often, a slight delay of reproduction decreases POPULATION GROWTH more strongly than does even a fairly large reduction in reproductive rate.

Lift

Given a MAP f from a SPACE X to a SPACE Y and another MAP g from a SPACE Z to a SPACE Y, a lift is a MAP h from X to Z such that $gh = f$. In other words, a lift of f is a MAP h such that the diagram (shown below) commutes.

If f is the identity from Y to Y, a MANIFOLD, and if g is the BUNDLE PROJECTION from the TANGENT BUNDLE to Y, the lifts are precisely VECTOR FIELDS. If g is a bundle projection from any FIBER BUNDLE to Y, then lifts are precisely sections. If f is the identity from Y to Y, a MANIFOLD, and g a projection from the orientation double cover of Y, then lifts exist IFF Y is an orientable MANIFOLD.

If f is a MAP from a CIRCLE to Y, an n-MANIFOLD, and g the bundle projection from the FIBER BUNDLE of alternating K-FORMS on Y, then lifts always exist IFF Y is orientable. If f is a MAP from a region in the COMPLEX PLANE to the COMPLEX PLANE (complex analytic), and if g is the exponential MAP, lifts of f are precisely LOGARITHMS of f.

See also LIFTING PROBLEM

Lifting Problem

Given a MAP f from a SPACE X to a SPACE Y and another MAP g from a SPACE Z to a SPACE Y, does there exist a MAP h from X to Z such that $gh = f$? If such a map h exists, then h is called a LIFT of f.

See also EXTENSION PROBLEM, LIFT

Ligancy

KISSING NUMBER

Likelihood

The hypothetical PROBABILITY that an event which has already occurred would yield a specific outcome. The concept differs from that of a probability in that a probability refers to the occurrence of future events, while a likelihood refers to past events with known outcomes.

See also LIKELIHOOD RATIO, MAXIMUM LIKELIHOOD, NEGATIVE LIKELIHOOD RATIO, PROBABILITY

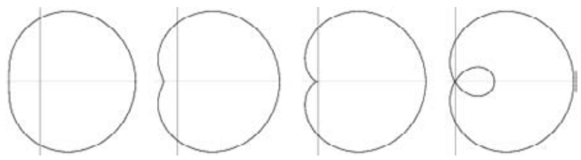
Likelihood Ratio

A quantity used to test NESTED HYPOTHESES. Let H' be a NESTED HYPOTHESIS with n' DEGREES OF FREEDOM within H (which has n DEGREES OF FREEDOM), then calculate the MAXIMUM LIKELIHOOD of a given outcome, first given H', then given H. Then

$$\mathrm{LR} = \frac{[\text{likelihood } H']}{[\text{likelyhood } H]}.$$

Comparison of this ratio to the critical value of the CHI-SQUARED DISTRIBUTION with $n - n'$ DEGREES OF FREEDOM then gives the SIGNIFICANCE of the increase in LIKELIHOOD.

The term likelihood ratio is also used (especially in medicine) to test nonnested complementary hypotheses as follows,



$$LR = \frac{[\text{true positive rate}]}{[\text{false positive rate}]} = \frac{[\text{sensitivity}]}{1 - [\text{specificity}]}.$$

See also NEGATIVE LIKELIHOOD RATIO, SENSITIVITY, SPECIFICITY

Limaçon of Pascal

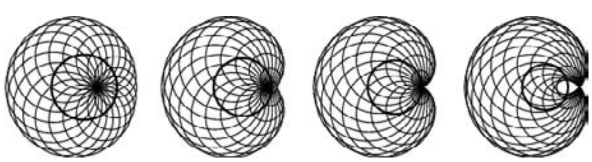
LIMAÇON

Limaçon

The limaçon is a polar curve OF THE FORM

$$r = b + a \cos \theta$$

also called the LIMAÇON OF PASCAL. It was first investigated by Dürer, who gave a method for drawing it in *Underweysung der Messung* (1525). It was rediscovered by Étienne Pascal, father of Blaise Pascal, and named by Gilles-Personne Roberval in 1650 (MacTutor Archive). The word "limaçon" comes from the Latin *limax*, meaning "snail."



If $b \geq 2a$, we have a convex limaçon. If $2a > b > a$, we have a dimpled limaçon. If $b = a$, the limaçon degenerates to a CARDIOID. If $b < a$, we have limaçon with an inner loop. If $b = a/2$, it is a TRISECTRIX (but *not* the MACLAURIN TRISECTRIX) with inner loop of AREA

$$A_{\text{inner loop}} = \tfrac{1}{4} a^2 \left(\pi - 3 \sqrt{\frac{3}{2}} \right),$$

and AREA between the loops of

$$A_{\text{between loops}} = \tfrac{1}{4} a^2 \left(\pi + 3 \sqrt{3} \right)$$

(MacTutor Archive).

The limaçon can be generated by specifying a fixed point P, then drawing a sequences of circles with centers on a given circle which all pass through P. The ENVELOPE of these curves is a limaçon. If the fixed point is on the CIRCUMFERENCE of the circle, then the ENVELOPE is a CARDIOID.

The limaçon is an ANALLAGMATIC CURVE, and is also the CATACAUSTIC of a CIRCLE when the RADIANT POINT is a finite (NONZERO) distance from the CIRCUMFERENCE, as shown by Thomas de St. Laurent in 1826 (MacTutor Archive). The limaçon is the CONCHOID of a CIRCLE with respect to a point on its CIRCUMFERENCE (Wells 1991).

See also CARDIOID

Limaçon Evolute

The CATACAUSTIC of a CIRCLE for a RADIANT POINT is the limaçon evolute. It has PARAMETRIC EQUATIONS

$$x = \frac{a[4a^2 + 4b^2 + 9ab \cos t - ab \cos(3t)]}{4(2a^2 + b^2 + 3ab \cos t)}$$

$$y = \frac{a^2 b \sin^3 t}{2a^2 + b^2 + 3ab \cos t}.$$

Limb

A limb of a TREE at a vertex v is the union of one or more BRANCHES at v in the tree. v is then called the base of the limb.

Lim Inf

INFIMUM LIMIT

Limit

A function $f(z)$ is said to have a limit $\lim_{z \to a} f(z) = c$ if, for all $\epsilon > 0$, there exists a $\delta > 0$ such that $|f(z) - c| < \epsilon$ whenever $0 < |z - a| < \delta$. This form of definition is sometimes called an EPSILON-DELTA DEFINITION. Limits may be taken from below

$$\lim_{z \to a^-} = \lim_{x \uparrow a} \tag{1}$$

or from above

$$\lim_{z\to a^+} = \lim_{z\downarrow a}. \qquad (2)$$

if the two are equal, then "the" limit is said to exist

$$\lim_{z\to a} = \lim_{z\to a^-} = \lim_{z\to a^+}. \qquad (3)$$

A LOWER LIMIT h

$$\text{lower} \lim_{n\to\infty} S_n = \underline{\lim}_{n\to\infty} S_n = h \qquad (4)$$

is said to exist if, for every $\epsilon > 0$, $|S_n - h| < \epsilon$ for infinitely many values of n and if no number less than h has this property.

An UPPER LIMIT k

$$\text{upper} \lim_{n\to\infty} S_n = \overline{\lim}_{n\to\infty} S_n = k \qquad (5)$$

is said to exist if, for every $\epsilon > 0$, $|S_n - h| < \epsilon$ for infinitely many values of n and if no number larger than k has this property.

INDETERMINATE limit forms of types ∞/∞ and $0/0$ can often be computed with L'HOSPITAL'S RULE. Types $0 \cdot \infty$ can be converted to the form $0/0$ by writing

$$f(x)g(x) = \frac{f(x)}{1/g(x)}. \qquad (6)$$

Types 0^0, ∞^0, and 1^∞ are treated by introducing a dependent variable

$$y = f(x)^{g(x)} \qquad (7)$$

so that

$$\ln y = g(x)\ln[f(x)], \qquad (8)$$

then calculating $\lim \ln y$. The original limit then equals $e^{\lim \ln y}$,

$$L = \lim f(x)^{g(x)} = e^{\lim \ln y} \qquad (9)$$

The INDETERMINATE form $\infty - \infty$ is also frequently encountered.

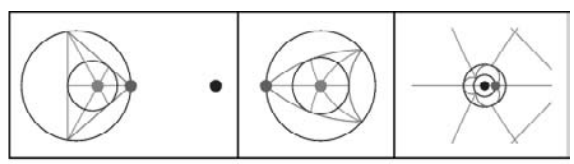
Limit Comparison Test

Let Σa_k and Σb_k be two SERIES with POSITIVE terms and suppose

$$\lim_{k\to\infty} \frac{a_k}{b_k} = \rho.$$

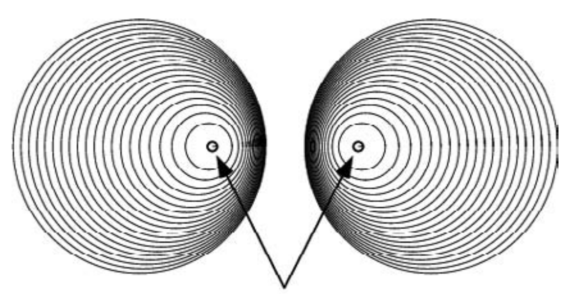
If ρ is finite and $\rho > 0$, then the two SERIES both CONVERGE or DIVERGE.



See also CONVERGENCE TESTS, LIMIT, LIMIT TEST

Limit Cycle

An attracting set to which orbits or trajectories converge and upon which trajectories are periodic.



See also HOPF BIFURCATION

Limiting Point

Poncelet's porism *inversion about* ● *inversion about* ●

A point about which INVERSION of two circles produced CONCENTRIC CIRCLES. Every pair of distinct circles has two limiting points.

point circles (limit points)

The limiting points correspond to the POINT CIRCLES of a COAXAL SYSTEM, and the limiting points of a COAXAL SYSTEM are INVERSE POINTS with respect to any circle of the system.

To find the limiting point of two circles of radii r and R with centers separated by a distance d, set up a coordinate system centered on the circle of radius R and with the other circle centered at $(d, 0)$. Then the equation for the position of the center of the inverted circles with inversion center $(x_0, 0)$,

$$x' = x_0 + \frac{k^2(x - x_0)}{(x - x_0)^2 + (y - y_0)^2 - a^2}, \quad (1)$$

becomes

$$x'_1 = x_0 + \frac{k^2(d - x_0)}{(d - x_0)^2 - r^2} \quad (2)$$

$$x'_2 = x_0 + \frac{k^2(0 - x_0)}{(0 - x_0)^2 - R^2} \quad (3)$$

for the first and second circles, respectively. Setting $x'_1 = x'_2$ gives

$$\frac{d - x_0}{(d - x_0)^2 - r^2} = \frac{-x_0}{x_0^2 - R^2}, \quad (4)$$

and solving using the quadratic equation gives the positions of the limiting points as

$$x' = \frac{d^2 - r^2 + R^2 \pm \sqrt{(d^2 - r^2 + R^2)^2 - 4d^2R^2}}{2d}. \quad (5)$$

Limit Ordinal

An ordinal number $\alpha > 0$ is called a limit ordinal iff it has no immediate predecessor, i.e., if there is no ordinal number β such that $\beta + 1 = \alpha$ (Ciesielski 1997, p. 46; Moore 1982, p. 60; Rubin 1967, p. 182; Suppes 1972, p. 196). The first limit ordinal is ω.

Limit Test

If $\lim a_n \neq 0$ or this limit does not exist as n tends to infinity, then the infinite series Σa_n does not converge. For example, $\Sigma_{n=1}^{\infty}(-1)^n$ does not converge by the limit test. The limit test is inconclusive when the limit is zero.

Limit Theorem

Central Limit Theorem, Lebesgue's Dominated Convergence Theorem Lindeberg-Feller Central Limit Theorem, Monotone Convergence Theorem, Pointwise Convergence

Lim Sup

Supremum Limit

Lindeberg Condition

A sufficient condition on the Lindeberg-Feller central limit theorem. Given random variates X_1, X_2, ..., let $\langle X_i \rangle = 0$, the variance σ_i^2 of X_i be finite, and variance of the distribution consisting of a sum of X_is

$$S_n \equiv X_1 + X_2 + \ldots + X_n \quad (1)$$

be

$$s_n^2 \equiv \sum_{i=1}^{n} \sigma_i^2. \quad (2)$$

In the terminology of Zabell (1995), let

$$\Lambda_n(\epsilon) \equiv \sum_{k=1}^{n} \left\langle \left(\frac{X_k}{s_n}\right)^2 : \frac{|X_k|}{s_n} \geq \epsilon \right\rangle, \quad (3)$$

where $\langle f : g \rangle$ denotes the expectation value of f restricted to outcomes g, then the Lindeberg condition is

$$\lim_{n \to \infty} \Lambda_n(\epsilon) = 0 \quad (4)$$

for all $\epsilon > 0$ (Zabell 1995).

In the terminology of Feller (1971), the Lindeberg condition assumed that for each $t > 0$,

$$\frac{1}{s_n^2} \sum_{k=1}^{n} \int_{|y| \geq ts_n} y^2 F_k\{dy\} \to 0, \quad (5)$$

or equivalently

$$\frac{1}{s_n^2}\sum_{k=1}^{n}\int_{|y|<ts_n} y^2 F_k\{dy\} \to 1. \quad (6)$$

Then the distribution

$$S_n{}^* = \frac{X_1 + \ldots + X_n}{s_n} \quad (7)$$

tends to the NORMAL DISTRIBUTION with zero expectation and unit variance (Feller 1971, p. 256). The Lindeberg condition (5) guarantees that the individual variances σ_k^2 are small compared to their sum s_n^2 in the sense that for given $\epsilon > 0$ for for all SUFFICIENTLY LARGE n, $\sigma_k/s_n < \epsilon$ for $k = 1, ..., n$ (Feller 1971, p. 256).

Line

Euclid defined a line as a "breadthless length," and a straight line as a line which "lies evenly with the points on itself" (Kline 1956, Dunham 1990). Lines are intrinsically 1-dimensional objects, but may be embedded in higher dimensional SPACES. An infinite line passing through points A and B is denoted $\overleftrightarrow{AB}$. A

LINE SEGMENT terminating at these points is denoted $\overline{AB}$. A line is sometimes called a STRAIGHT LINE or, more archaically, a RIGHT LINE (Casey 1893), to emphasize that it has no curves anywhere along its length.

Harary (1994) called an edge of a graph a "line."

Consider first lines in a 2-D PLANE. The line with x-INTERCEPT a and y-INTERCEPT b is given by the *intercept form*

$$\frac{x}{a}+\frac{y}{b}=1. \tag{1}$$

The line through (x_1, y_1) with SLOPE m is given by the *point-slope form*

$$y-y_1=m(x-x_1). \tag{2}$$

The line with y-intercept b and slope m is given by the *slope-intercept form*

$$y=mx+b. \tag{3}$$

The line through (x_1, y_1) and (x_2, y_2) is given by the *two point form*

$$y-y_1=\frac{y_2-y_1}{x_2-x_1}(x-x_1). \tag{4}$$

Other forms are

$$a(x-x_1)+b(y-y_1)=0 \tag{5}$$

$$ax+by+c=0 \tag{6}$$

$$\begin{vmatrix} x & y & 1 \\ x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \end{vmatrix}=0. \tag{7}$$

A line in 2-D can also be REPRESENTED AS A VECTOR. The VECTOR along the line

$$ax+by=0 \tag{8}$$

is given by

$$t\begin{bmatrix} -b \\ a \end{bmatrix}, \tag{9}$$

where $t\in\mathbb{R}$. Similarly, VECTORS OF THE FORM

$$t\begin{bmatrix} a \\ b \end{bmatrix} \tag{10}$$

are PERPENDICULAR to the line. Three points lie on a line if

$$\begin{vmatrix} x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \\ x_3 & y_3 & 1 \end{vmatrix}=0. \tag{11}$$

The ANGLE between lines

$$A_1x+B_1y+C_1=0 \tag{12}$$

$$A_2x+B_2y+C_2=0 \tag{13}$$

is

$$\tan\theta=\frac{A_1B_2-A_2B_1}{A_1A_2+B_1B_2}. \tag{14}$$

The line joining points with TRILINEAR COORDINATES $\alpha_1:\beta_1:\gamma_1$ and $\alpha_2:\beta_2:\gamma_2$ is the set of point $\alpha:\beta:\gamma$ satisfying

$$\begin{vmatrix} \alpha & \beta & \gamma \\ \alpha_1 & \beta_1 & \gamma_1 \\ \alpha_2 & \beta_2 & \gamma_2 \end{vmatrix}=0 \tag{15}$$

$$(\beta_1\gamma_2-\gamma_1\beta_2)\alpha+(\gamma_1\alpha_2-\alpha_1\gamma_2)\beta+(\alpha_1\beta_2-\beta_1\alpha_2)\gamma =0. \tag{16}$$

Three lines CONCUR if their TRILINEAR COORDINATES satisfy

$$l_1\alpha+m_1\beta+n_1\gamma=0 \tag{17}$$

$$l_2\alpha+m_2\beta+n_2\gamma=0 \tag{18}$$

$$l_3\alpha+m_3\beta+n_3\gamma=0, \tag{19}$$

in which case the point is

$$m_2n_3-n_2m_3:n_2l_3-l_2n_3:l_2m_3-m_2l_3, \tag{20}$$

or if the COEFFICIENTS of the lines

$$A_1x+B_1y+C_1=0 \tag{21}$$

$$A_2x+B_2y+C_2=0 \tag{22}$$

$$A_3x+B_3y+C_3=0 \tag{23}$$

satisfy

$$\begin{vmatrix} A_1 & B_1 & C_1 \\ A_2 & B_2 & C_2 \\ A_3 & B_3 & C_3 \end{vmatrix}=0. \tag{24}$$

Two lines CONCUR if their TRILINEAR COORDINATES satisfy

$$\begin{vmatrix} l_1 & m_1 & n_1 \\ l_2 & m_2 & n_2 \\ l_3 & m_3 & n_3 \end{vmatrix}=0. \tag{25}$$

The line through P_1 is the direction (a_1, b_1, c_1) and the line through P_2 in direction (a_2, b_2, c_2) intersect IFF

$$\begin{vmatrix} x_2-x_1 & y_2-y_1 & z_2-z_1 \\ a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \end{vmatrix}=0. \tag{26}$$

The line through a point $\alpha':\beta':\gamma'$ PARALLEL to

$$l\alpha+m\beta+n\gamma=0 \tag{27}$$

is

$$\begin{vmatrix} \alpha & \beta & \gamma \\ \alpha' & \beta' & \gamma' \\ bn-cm & cl-an & am-bl \end{vmatrix} = 0. \tag{28}$$

The lines

$$l\alpha + m\beta + n\gamma = 0 \tag{29}$$

$$l'\alpha + m'\beta + n'\gamma = 0 \tag{30}$$

are PARALLEL if

$$a(mn' - nm') + b(nl' - ln') + c(lm' - ml') = 0 \tag{31}$$

for all (a, b, c), and PERPENDICULAR if

$$2abc(ll' + mm' + nn') - (mn' + m'm)\cos A$$

$$-(nl' + n'l)\cos B - (lm' + l'm)\cos C = 0 \tag{32}$$

for all (a, b, c) (Sommerville 1924). The line through a point $\alpha' : \beta' : \gamma'$ PERPENDICULAR to (32) is given by

$$\begin{vmatrix} \alpha & \beta & \gamma \\ \alpha' & \beta' & \gamma' \\ l - m\cos C & m - n\cos A & n - l\cos B \\ -n\cos B & -l\cos C & -m\cos A \end{vmatrix} = 0. \tag{33}$$

In 3-D SPACE, the line passing through the point (x_0, y_0, z_0) and PARALLEL to the NONZERO VECTOR

$$\mathbf{v} = \begin{bmatrix} a \\ b \\ c \end{bmatrix} \tag{34}$$

has PARAMETRIC EQUATIONS

$$x = x_0 + at \tag{35}$$

$$y = y_0 + bt \tag{36}$$

$$z = z_0 + ct, \tag{37}$$

written concisely as

$$\mathbf{x} = \mathbf{x}_0 + \mathbf{v}t. \tag{38}$$

Similarly, the line in 3-D passing through (x_1, y_1) and (x_2, y_2) has parametric vector equation

$$\mathbf{x} = \mathbf{x}_1 + (\mathbf{x}_2 - \mathbf{x}_1)t, \tag{39}$$

where this parametrization corresponds to $\mathbf{x}(t=0) = \mathbf{x}_1$ and $\mathbf{x}(t=1) = \mathbf{x}_2$.

Linear Algebra

The study of linear sets of equations and their transformation properties. Linear algebra allows the analysis of ROTATIONS in space, LEAST SQUARES FITTING, solution of coupled differential equations, determination of a circle passing through three given points, as well as many other problems in mathematics, physics, and engineering.

The MATRIX and DETERMINANT are extremely useful tools of linear algebra. One central problem of linear algebra is the solution of the matrix equation

$$\mathsf{A}\mathbf{x} = \mathbf{b}$$

for $\mathbf{x}$. While this can, in theory, be solved using a MATRIX INVERSE

$$\mathbf{x} = \mathsf{A}^{-1}\mathbf{b},$$

other techniques such as GAUSSIAN ELIMINATION are numerically more robust.

Linear Algebraic Group

A linear algebraic group is a GROUP which is also an AFFINE VARIETY. In particular, its elements satisfy polynomial equations. For example, $GL(n)$, the GENERAL LINEAR GROUP, is a linear algebraic group because an INVERTIBLE MATRIX is given by n^2 entries that satisfy the polynomial $\det a_n = 1$. The group operations are required to be given by REGULAR RATIONAL FUNCTIONS. The linear algebraic groups are similar to the LIE GROUPS, except that linear algebraic groups may be defined over any FIELD, including those of positive CHARACTERISTIC.

See also AFFINE VARIETY, ALGEBRAIC GROUP, FORMAL GROUP, GROUP, GROUP SCHEME, LIE ALGEBRA, LIE GROUP, VARIETY

Linear Approximation

A linear approximation to a function $f(x)$ at a point x_0 can be computed by taking the first term in the TAYLOR SERIES

$$f(x_0 + \Delta x) = f(x_0) + f'(x_0)\Delta x + \ldots.$$

See also MACLAURIN SERIES, TAYLOR SERIES

Linear Code

A linear code over a FINITE FIELD with q elements F_q is a linear SUBSPACE $C \subset F_q^n$. The vectors forming the SUBSPACE are called code words. When code words are chosen such that the distance between them is maximized, the code is called error-correcting since slightly garbled vectors can be recovered by choosing the nearest code word.

See also CODE, CODING THEORY, ERROR-CORRECTING CODE, GRAY CODE, HUFFMAN CODING, ISBN, UPC

Linear Combination

A sum of the elements from some set with constant coefficients placed in front of each. For example, a linear combination of the VECTORS $\mathbf{x}$, $\mathbf{y}$, and $\mathbf{z}$ is given by

$$a\mathbf{x} + b\mathbf{y} + c\mathbf{z},$$

where a, b, and c are constants.

See also BASIS, BASIS (VECTOR SPACE), SPAN (VECTOR SPACE)

Linear Congruence Equation

A linear congruence equation

$$ax \equiv b \pmod{m} \tag{1}$$

is solvable IFF the CONGRUENCE

$$b \equiv 0 \pmod{d} \tag{2}$$

is solvable, where $d \equiv \mathrm{GCD}(a, m)$ is the GREATEST COMMON DIVISOR. Let one solution to the original equation be $x_0 < m/d$. Then the solutions are $x = x_0$, $x_0 + m/d$, $x_0 + 2m/d$, ..., $x_0 + (d-1)m/d$. If $d = 1$, then there is only one solution $< m$. The solution of a linear congruence can be found in *Mathematica* using Solve[$ax == b$ && Modulus $== m$, x].

Solution to a linear congruence equation is equivalent to finding the value of a fractional CONGRUENCE, for which a greedy-type algorithm exists. In particular, (1) can be rewritten as

$$x \equiv \frac{b}{a} \pmod{m} \tag{3}$$

which can also be written

$$\frac{x}{b} \equiv \frac{1}{a} \pmod{m}. \tag{4}$$

In this form, the solution x can be found as Mod[by,

m] of the solution y returned by the *Mathematica* command $y =$ PowerMod[a, -1, m].

Linear Congruence Method

A method for generating random (pseudorandom) numbers using the linear recurrence relation

$$X_{n+1} = aX_n + c \pmod m,$$

where a and c must assume certain fixed values and X_0 is an initial number known as the seed.

See also Pseudorandom Number, Random Number, Seed

Linear Diophantine Equation

Diophantine Equation

Linear Equation

An algebraic equation of the form

$$y = ax + b$$

involving only a constant and a first-order (linear) term.

See also Line, Polynomial, Quadratic Equation

Linear Equation System

When solving a system of n linear equations with $k > n$ unknowns, use matrix operations to solve the system as far as possible. Then solve for the first $(k - n)$ components in terms of the last n components to find the solution space.

Linear Extension

A linear extension of a partially ordered set P is a permutation of the elements $p_1, p_2, \ldots$ of P such that $i < j$ implies $p_i < p_j$. For example, the linear extensions of the partially ordered set $((1,\ 2), (3,\ 4))$ are 1234, 1324, 1342, 3124, 3142, and 3412, all of which have 1 before 2 and 3 before 4.

Linear Fractional Transformation

A transformation of the form

$$w = f(z) = \frac{az + b}{cz + d}, \tag{1}$$

where $a, b, c, d \in \mathbb{C}$ and

$$ad - bc \neq 0, \tag{2}$$

is a conformal mapping called a linear fractional transformation. The transformation can be extended to the entire extended complex plane $\mathbb{C}^* = \mathbb{C} \cup \{\infty\}$ by defining

$$f\left(-\frac{d}{c}\right) = \infty \tag{3}$$

$$f(\infty) = \frac{a}{c} \tag{4}$$

(Apostol 1997, p. 26). The linear fractional transformation is linear in both w and z, and analytic everywhere except for a simple pole at $z = -d/c$.

Every linear fractional transformation except $f(z) = z$ has one or two fixed points. The linear fractional transformation sends circles and lines to circles or lines. Linear fractional transformations preserve symmetry. The cross-ratio is invariant under a linear fractional transformation. A linear fractional transformation is a composition of translations, rotations, magnifications, and inversions.

To determine a particular linear fractional transformation, specify the map of three points which preserve orientation. A particular linear fractional transformation is then uniquely determined. To determine a general linear fractional transformation, pick two symmetric points α and α_S. Define $\beta \equiv f(\alpha)$, restricting β as required. Compute β_S. $f(\alpha_S)$ then equals β_S since the linear fractional transformation preserves symmetry (the symmetry principle). Plug in α and α_S into the general linear fractional transformation and set equal to β and β_S. Without loss of generality, let $c = 1$ and solve for a and b in terms of β. Plug back into the general expression to obtain a linear fractional transformation.

Linear Function

A linear function is a function f which satisfies

$$f(x+y)=f(x)+f(y)$$

and

$$f(\alpha x)=\alpha f(x)$$

for all x and y in the domain, and all scalars α.

See also Bilinear Function, Function, Vector Space

Linear Functional

A linear functional on a real vector space V is a function $T: V \to \mathbb{R}$, which satisfies the following properties.

1. $T(v+w)=T(v)+T(w)$, and
2. $T(\alpha v)=\alpha T(v)$.

When V is a complex vector space, then T is a linear map into the complex numbers.

Distributions are a special case of linear functionals, and have a rich theory surrounding them.

Linear Map

Linear Transformation

Linear Operator

An operator $\tilde{L}$ is said to be linear if, for every pair of functions f and g and scalar t,

$$\tilde{L}(f+g)=\tilde{L}f+\tilde{L}g$$

and

$$\tilde{L}(tf)=t\tilde{L}f.$$

Linear Ordinary Differential Equation

Ordinary Differential Equation–First-Order, Ordinary Differential Equation–Second-Order

Linear Programming

The problem of maximizing a linear function over a convex polyhedron, also known as operations research, optimization theory, or convex optimization theory. Linear programming is extensively used in economics and engineering. Examples from economics include Leontief's input-output model, the determination of shadow prices, etc., while an example of an engineering application would be maximizing profit in a factory that manufactures a number of different products from the same raw material using the same resources.

Linear programming can be solved using the simplex method (Wood and Dantzig 1949, Dantzig 1949) which runs along edges of the visualization solid to find the best answer. In 1979, L. G. Khachian found a $\mathcal{O}(x^5)$ polynomial-time algorithm. A much more efficient polynomial-time algorithm was found by Karmarkar (1984). This method goes through the middle of the solid and then transforms and warps, and offers many advantages over the simplex method. Karmarkar's method is patented, so it has not received much detailed discussion.

Linear Space

VECTOR SPACE

Linear Stability

Consider the general system of two first-order ORDINARY DIFFERENTIAL EQUATIONS

$$\dot{x} = f(x, y) \tag{1}$$

$$\dot{y} = g(x, y). \tag{2}$$

Let x_0 and y_0 denote FIXED POINTS with $\dot{x} = \dot{y} = 0$, so

$$f(x_0, y_0) = 0 \tag{3}$$

$$g(x_0, y_0) = 0. \tag{4}$$

Then expand about (x_0, y_0) so

$$\delta\dot{x} = f_x(x_0, y_0)\delta x + f_y(x_0, y_0)\delta y + f_{xy}(x_0, y_0)\delta x\delta y + \cdots \tag{5}$$

$$\delta\dot{y} = g_x(x_0, y_0)\delta x + g_y(x_0, y_0)\delta y + g_{xy}(x_0, y_0)\delta x\delta y + \cdots \tag{6}$$

To first-order, this gives

$$\frac{d}{dt}\begin{bmatrix}\delta x\\ \delta y\end{bmatrix} = \begin{bmatrix}f_x(x_0, y_0) & f_y(x_0, y_0)\\ g_x(x_0, y_0) & g_y(x_0, y_0)\end{bmatrix}\begin{bmatrix}\delta x\\ \delta y\end{bmatrix}, \tag{7}$$

where the 2×2 MATRIX is called the STABILITY MATRIX.

In general, given an n-D MAP $\mathbf{x}' = T(\mathbf{x})$, let $\mathbf{x}_0$ be a FIXED POINT, so that

$$T(\mathbf{x}_0) = \mathbf{x}_0. \tag{8}$$

Expand about the fixed point,

$$T(\mathbf{x}_0 + \delta\mathbf{x}) = T(\mathbf{x}_0) + \frac{\partial T}{\partial \mathbf{x}}\,\delta\mathbf{x} + \mathcal{O}(\delta\mathbf{x})^2$$

$$\equiv T(\mathbf{x}_0) + \delta T, \tag{9}$$

so

$$\delta T = \frac{\partial T}{\partial \mathbf{x}}\,\delta\mathbf{x} \equiv \mathsf{A}\delta\mathbf{x}. \tag{10}$$

The map can be transformed into the principal axis frame by finding the EIGENVECTORS and EIGENVALUES of the MATRIX A

$$(\mathsf{A} - \lambda\mathsf{I})\delta\mathbf{x} = 0, \tag{11}$$

so the DETERMINANT

$$|\mathsf{A} - \lambda\mathsf{I}| = 0. \tag{12}$$

The mapping is

$$\delta\mathbf{x}'_{\text{princ}} = \begin{bmatrix}\lambda_1 & \cdots & 0\\ \vdots & \ddots & \vdots\\ 0 & \cdots & \lambda_n\end{bmatrix}. \tag{13}$$

When iterated a large number of times,

$$\delta T'_{\text{princ}} \to 0 \tag{14}$$

only if $|\Re(\lambda_i)| < 1$ for $i = 1, \ldots, n$ but $\to \infty$ if any $|\lambda_i| > 1$. Analysis of the EIGENVALUES (and EIGENVECTORS) of A therefore characterizes the type of FIXED POINT. The condition for stability is $|\Re(\lambda_i)| < 1$ for $i = 1, \ldots, n$.

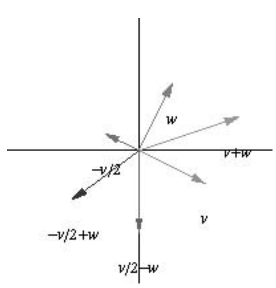
Linear Transformation

A linear transformation between two VECTOR SPACES V and W is a MAP $T : V \to W$ such that the following hold:

1. $T(\mathbf{v}_1 + \mathbf{v}_2) = T(\mathbf{v}_1)T(\mathbf{v}_2)$ for any VECTORS $\mathbf{v}_1$ and $\mathbf{v}_2$ in V, and
2. $T(\alpha\mathbf{v}) = \alpha T(\mathbf{v})$ for any SCALAR α.

A linear transformation may not be INJECTIVE or ONTO. When V and W have the same DIMENSION, it is possible for T to be invertible, meaning there exists a T^{-1} such that $TT^{-1} = I$. It is always the case that $T(0) = 0$. Also, a linear transformation always maps LINES to LINES (or to zero).



nbsp

The main example of a linear transformation is given by MATRIX MULTIPLICATION. Given an $n \times m$ MATRIX A, define $T(\mathbf{v}) = \mathsf{A}\mathbf{v}$, where $\mathbf{v}$ is written as a COLUMN VECTOR (with m coordinates). For example, consider

$$\mathsf{A} = \begin{bmatrix} 0 & 1 \\ -1 & 3 \\ 4 & 0 \end{bmatrix}, \tag{1}$$

then T is a linear transformation from $\mathbb{R}^2$ to $\mathbb{R}^3$, defined by,

$$T(x,\ y) = (y, -2x + 2y,\ x). \tag{2}$$

Another example is $T(x,\ y) = (1.4x - y,\ 0.8x)$. The homotopy from the identity transformation to T is illustrated above.

When V and W are FINITE dimensional, a general linear transformation can be written as a matrix multiplication only after specifying a BASIS for V and W. When V and W have an INNER PRODUCT, and their BASES, $\{v_1,\ \cdots,\ v_m\}$ and $\{w,\ \cdots,\ w_n\}$, are ORTHONORMAL, it is easy to write the corresponding matrix $A = (a_{ij})$. In particular, $a_{ij} = \langle w_i,\ T(v_j)\rangle$. Note that when using the standard basis for $\mathbb{R}^n$ and $\mathbb{R}^m$, the jth column corresponds to the image of the jth standard basis vector.

When V and W are INFINITE dimensional, then it is possible for a linear transformation to not be CONTINUOUS. For example, let V be the space of polynomials in one variable, and T be the DERIVATIVE. Then $T(x^3) = nx^{n-1}$, which is not CONTINUOUS because $x^n/n \to 0$ while $T(x^n/n)$ does not converge.

Linear 2-D transformations have a simple classification. Consider the 2-D linear transformation

$$\rho x'_1 = a_{11}x_1 + a_{12}x_2 \tag{3}$$

$$\rho x'_2 = a_{21}x_1 + a_{22}x_2. \tag{4}$$

Now rescale by defining $\lambda \equiv x_1/x_2$ and $\lambda' \equiv x'_1/x'_2$. Then the above equations become

$$\lambda' = \frac{\alpha\lambda + \beta}{\gamma\lambda + \delta} \tag{5}$$

where $\alpha\delta - \beta\gamma \neq 0$ and α, β, γ and δ are defined in terms of the old constants. Solving for λ gives

$$\lambda = \frac{\delta\lambda' - \beta}{-\gamma\lambda' + \alpha}, \tag{6}$$

so the transformation is ONE-TO-ONE. To find the FIXED POINTS of the transformation, set $\lambda = \lambda'$ to obtain

$$\gamma\lambda^2 + (\delta - \alpha)\lambda - \beta = 0. \tag{7}$$

This gives two fixed points which may be distinct or coincident. The fixed points are classified as follows.

variables	type
$(\delta - \alpha)^2 + 4\beta\gamma > 0$	HYPERBOLIC FIXED POINT
$(\delta - \alpha)^2 + 4\beta\gamma < 0$	ELLIPTIC FIXED POINT
$(\delta - \alpha)^2 + 4\beta\gamma = 0$	PARABOLIC FIXED POINT

Linear Weighted Moment

L-MOMENT

Linearly Dependent Curves

Two curves ϕ and ψ satisfying

$$\phi + \psi = 0$$

are said to be linearly dependent. Similarly, n curves ϕ_i, $i = 1, ..., n$ are said to be linearly dependent if

$$\sum_{i=1}^{n} \phi_i = 0.$$

See also BERTINI'S THEOREM, STUDY'S THEOREM

References

Coolidge, J. L. *A Treatise on Algebraic Plane Curves.* New York: Dover, pp. 32–4, 1959.

Linearly Dependent Functions

The n functions $f_1(x)$, $f_2(x)$, ..., $f_n(x)$ are linearly dependent if, for some $c_1, c_2, ..., c_n \in \mathbb{R}$ not all zero,

$$c_i f_i(x) = 0 \quad (1)$$

(where EINSTEIN SUMMATION is used) for all x in some interval I. If the functions are not linearly dependent, they are said to be linearly independent. Now, if the functions $\in \mathbb{R}^{n-1}$, we can differentiate (1) up to $n-1$ times. Therefore, linear dependence also requires

$$c_i f'_i = 0 \quad (2)$$

$$c_i f''_i = 0 \quad (3)$$

$$c_i f_i^{(n-1)} = 0, \quad (4)$$

where the sums are over $i = 1, ..., n$. These equations have a nontrivial solution IFF the DETERMINANT

$$\begin{vmatrix} f_1 & f_2 & \cdots & f_n \\ f'_1 & f'_2 & \cdots & f'_2 \\ \vdots & \vdots & \ddots & \vdots \\ f_1^{(n-1)} & f_2^{(n-1)} & \cdots & f_n^{(n-1)} \end{vmatrix} = 0, \quad (5)$$

where the DETERMINANT is conventionally called the WRONSKIAN and is denoted $W(f_1, f_2, \ldots, f_n)$. If the WRONSKIAN $\neq 0$ for any value c in the interval I, then the only solution possible for (2) is $c_i = 0$ ($i = 1, ..., n$), and the functions are linearly independent. If, on the other hand, $W = 0$ for a range, the functions are linearly dependent in the range. This is equivalent to stating that if the vectors $\mathbf{V}[f_1(c)]$, ..., $\mathbf{V}[f_n(c)]$ defined by

$$\mathbf{V}[f_i(x)] = \begin{bmatrix} f_i(x) \\ f'_i(x) \\ f''_i(x) \\ \vdots \\ f_i^{n-1}(x) \end{bmatrix} \quad (6)$$

are linearly independent for at least one $c \in I$, then the functions f_i are linearly independent in I.

Sansone, G. "Linearly Independent Functions." §1.2 in *Orthogonal Functions, rev. English ed.* New York: Dover, pp. 2–, 1991.

Linearly Dependent Sequences

Sequences $x_n^{(1)}, x_n^{(2)}, ..., x_n^{(k)}$ are linearly independent if constants $c_1, c_2, ..., c_k$ (not all zero) exist such that

$$\sum_{i=1}^{k} c_i x_n^{(i)} = 0$$

for $n = 0, 1, ...$

See also CASORATIAN

References

Zwillinger, D. (Ed.). *CRC Standard Mathematical Tables and Formulae.* Boca Raton, FL: CRC Press, p. 229, 1995.

Linearly Dependent Vectors

n VECTORS $\mathbf{X}_1, \mathbf{X}_2, ..., \mathbf{X}_n$ are linearly dependent IFF there exist SCALARS $c_1, c_2, ..., c_n$, not all zero, such that

$$c_i \mathbf{X}_i = 0, \quad (1)$$

where EINSTEIN SUMMATION is used and $i = 1, ..., n$. If no such SCALARS exist, then the vectors are said to be linearly independent. In order to satisfy the CRITERION for linear dependence,

$$c_1 \begin{bmatrix} x_{11} \\ x_{12} \\ \vdots \\ x_{n1} \end{bmatrix} + c_2 \begin{bmatrix} x_{12} \\ x_{22} \\ \vdots \\ x_{n2} \end{bmatrix} + \cdots + c_n \begin{bmatrix} x_{1n} \\ x_{2n} \\ \vdots \\ x_{nn} \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ \vdots \\ 0 \end{bmatrix} \quad (2)$$

$$\begin{bmatrix} x_{11} & x_{12} & \cdots & x_{1n} \\ x_{21} & x_{22} & \cdots & x_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ x_{n1} & x_{n2} & \cdots & x_{nn} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \\ \vdots \\ c_n \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ \vdots \\ 0 \end{bmatrix}. \quad (3)$$

In order for this MATRIX equation to have a nontrivial solution, the DETERMINANT must be 0, so the VECTORS are linearly dependent if

$$\begin{vmatrix} x_{11} & x_{12} & \cdots & x_{1n} \\ x_{21} & x_{22} & \cdots & x_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ x_{n1} & x_{n2} & \cdots & x_{nn} \end{vmatrix} = 0, \quad (4)$$

and linearly independent otherwise.

Let $\mathbf{p}$ and $\mathbf{q}$ be n-D VECTORS. Then the following three conditions are equivalent (Gray 1997).

1. **p** and **q** are linearly dependent.
2. $\begin{vmatrix} \mathbf{p}\cdot\mathbf{p} & \mathbf{p}\cdot\mathbf{q} \\ \mathbf{q}\cdot\mathbf{p} & \mathbf{q}\cdot\mathbf{q} \end{vmatrix} = 0.$
3. The $2 \times n$ MATRIX $\begin{bmatrix} \mathbf{p} \\ \mathbf{q} \end{bmatrix}$ has rank less than two.

Linearly Independent

Two or more functions, equations, or vectors $f_1, f_2, ...,$ which are not linearly dependent, i.e., cannot be expressed in the form

$$a_1 f_1 + a_2 f_2 + \cdots + a_n f_n = 0$$

with a_1, a_2, ... constants which are not all zero are said to be linearly independent.

Linearly Ordered Set

TOTAL ORDER

Line at Infinity

The straight line on which all POINTS AT INFINITY lie. The line at infinity is given in terms of TRILINEAR COORDINATES by

$$a\alpha + b\beta + c\gamma = 0,$$

which follows from the fact that a REAL TRIANGLE will have POSITIVE AREA, and therefore that

$$2\Delta = a\alpha + b\beta + c\gamma > 0.$$

Instead of the three reflected segments concurring for the ISOGONAL CONJUGATE of a point X on the CIRCUMCIRCLE of a TRIANGLE, they become parallel (and can be considered to meet at infinity). As X varies around the CIRCUMCIRCLE, X^{-1} varies through a line called the line at infinity. Every line is PERPENDICULAR to the line at infinity.

Poncelet was the first to systematically employ the line at infinity (Graustein 1930).

Line Bundle

A line bundle is a special case of a VECTOR BUNDLE in which the fiber is either $\mathbb{R}$, in the case of a real line bundle, or $\mathbb{C}$, in the case of a complex line bundle.

See also MANIFOLD, PRINCIPAL BUNDLE, TRIVIAL BUNDLE, VECTOR BUNDLE

Line-Circle Intersection

CIRCLE-LINE INTERSECTION

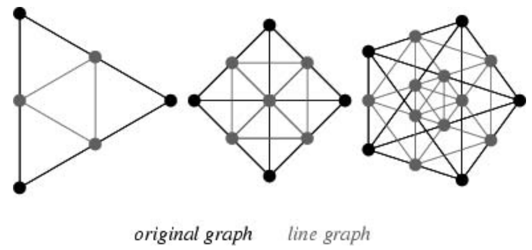
Line Connectivity

EDGE CONNECTIVITY

Line Element

Also known as the first FUNDAMENTAL FORM

$$ds^2 = g_{ab} dx^a dx^b.$$



In the principal axis frame for 3-D,

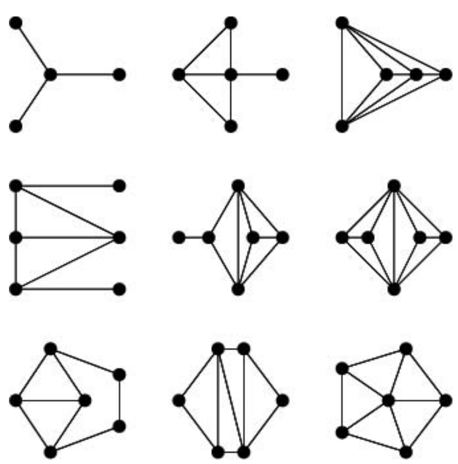
$$ds^2 = g_{aa}(dx^a)^2 + g_{bb}(dx^b)^2 + g_{cc}(dx^c)^2.$$

At ORDINARY POINTS on a surface, the line element is positive definite.

See also AREA ELEMENT, FUNDAMENTAL FORMS, VOLUME ELEMENT

Line Graph

A LINE GRAPH $L(G)$ (also called an interchange graph) of a graph G is obtained by associating a vertex with each edge of the graph and connecting two vertices with an edge IFF the corresponding edges of G meet at one or both endpoints. In the three examples above, the original graphs are the COMPLETE GRAPHS K_3, K_4, and K_5.



The line graph of a GRAPH with n nodes, e edges, and vertex degrees d_i contains $n' = e$ nodes and

$$e' = \frac{1}{2} \sum_{i=1}^{n} d_i^2 - e$$

edges (Skiena 1990, p. 137). The INCIDENCE MATRIX C of a graph and ADJACENCY MATRIX L of its line graph are related by

$$\mathsf{L} = \mathsf{C}^{\mathrm{T}} \mathsf{C} - 2\mathsf{I},$$

where I is the IDENTITY MATRIX (Skiena 1990, p. 136).

A graph is a line graph IFF if does not contain any of the above graphs as SUBGRAPHS (van Rooij and Wilf 1965; Beineke 1968; Skiena 1990, p. 138). Of the nine, one has four nodes (the STAR GRAPH $S_4 = K_{1,3}$), two have five nodes, and six have six nodes (including the WHEEL GRAPH W_6).

The only CONNECTED GRAPH that is isomorphic to its line graph is a CYCLE GRAPH C_n (Skiena 1990, p. 137). Whitney (1932) showed that, with the exception of K_3 and $K_{1,3}$, any two CONNECTED GRAPHS with isomorphic line graphs are isomorphic (Skiena 1990, p. 138).

The line graph of an EULERIAN GRAPH is both Eulerian and HAMILTONIAN (Skiena 1990, p. 138). More information about cycles of line graphs is given by Harary and Nash-Williams (1965) and Chartrand (1968).

Line Integral

The line integral of a VECTOR FIELD $\mathbf{F}(\mathbf{x})$ on a curve σ is defined by

$$\int_\sigma \mathbf{F} \cdot d\mathbf{s} = \int_a^b \mathbf{F}(\sigma(t)) \cdot \sigma'(t)\, dt, \tag{1}$$

where $\mathbf{a} \cdot \mathbf{b}$ denotes a DOT PRODUCT. In Cartesian coordinates, the line integral can be written

$$\int_\sigma \mathbf{F} \cdot d\mathbf{s} = \int_C F_1\, dx + F_2\, dy + F_3\, dz, \tag{2}$$

where

$$\mathbf{F} \equiv \begin{bmatrix} F_1(\mathbf{x}) \\ F_2(\mathbf{x}) \\ F_3(\mathbf{x}) \end{bmatrix}. \tag{3}$$

For z COMPLEX and $\gamma : z = z(t)$ a path in the COMPLEX PLANE parameterized by $t \in [a, b]$,

$$\int_\gamma f\, dz = \int_a^b f(z(t)) z'(t)\, dt. \tag{4}$$

POINCARÉ'S THEOREM states that if $\nabla \times \mathbf{F} = 0$ in a simply connected neighborhood $U(\mathbf{x})$ of a point $\mathbf{x}$, then in this neighborhood, $\mathbf{F}$ is the GRADIENT of a SCALAR FIELD $\phi(\mathbf{x})$,

$$\mathbf{F}(x) = -\nabla \phi(\mathbf{x}) \tag{5}$$

for $\mathbf{x} \in U(\mathbf{x})$, where ∇ is the gradient operator. Conse-

quently, the GRADIENT THEOREM gives

$$\int_\sigma \mathbf{F} \cdot d\mathbf{s} = \phi(\mathbf{x}_1) - \phi(\mathbf{x}_2) \quad (6)$$

for any path σ located completely within $U(\mathbf{x})$, starting at $\mathbf{x}_1$ and ending at $\mathbf{x}_2$.

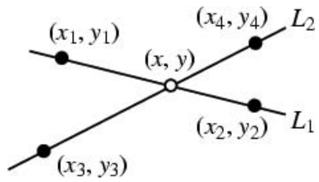
This means that if $\nabla \times \mathbf{F} = 0$ (i.e., $\mathbf{F}(\mathbf{x})$ is an IRROTATIONAL FIELD in some region), then the line integral is path-independent in this region. If desired, a Cartesian path can therefore be chosen between starting and ending point to give

$$\int_{(a,\, b,\, c)}^{(x,\, y,\, z)} F_1\, dx + F_2\, dy + F_3\, dz$$

$$= \int_{(a,\, b,\, c)}^{(x,\, b,\, c)} F_1\, dx + \int_{(x,\, b,\, c)}^{(x,\, y,\, c)} F_2\, dy + \int_{(x,\, y,\, c)}^{(x,\, y,\, z)} F_3\, dz. \quad (7)$$

If $\nabla \cdot \mathbf{F} = 0$ (i.e., $\mathbf{F}(\mathbf{x})$ is a DIVERGENCELESS FIELD, a.k.a. SOLENOIDAL FIELD), then there exists a VECTOR FIELD $\mathbf{A}$ such that

$$\mathbf{F} = \nabla \times \mathbf{A}, \quad (8)$$



where $\mathbf{A}$ is uniquely determined up to a gradient field (and which can be chosen so that $\nabla \cdot \mathbf{A} = 0$).

Line-Line Intersection

The INTERSECTION of two LINES L_1 and L_2 in 2-D with, L_1 containing the points (x_1, y_1) and (x_2, y_2), and L_2 containing the points (x_3, y_3) and (x_4, y_4), is given by

$$x = \frac{\begin{vmatrix} \begin{vmatrix} x_1 & y_1 \\ x_2 & y_2 \end{vmatrix} & \begin{vmatrix} x_1 & 1 \\ x_2 & 1 \end{vmatrix} \\ \begin{vmatrix} x_3 & y_3 \\ x_4 & y_4 \end{vmatrix} & \begin{vmatrix} x_3 & 1 \\ x_4 & 1 \end{vmatrix} \end{vmatrix}}{\begin{vmatrix} \begin{vmatrix} x_1 & 1 \\ x_2 & 1 \end{vmatrix} & \begin{vmatrix} y_1 & 1 \\ y_2 & 1 \end{vmatrix} \\ \begin{vmatrix} x_3 & 1 \\ x_4 & 1 \end{vmatrix} & \begin{vmatrix} y_3 & 1 \\ y_4 & 1 \end{vmatrix} \end{vmatrix}} = \frac{\begin{vmatrix} \begin{vmatrix} x_1 & y_1 \\ x_2 & y_2 \end{vmatrix} & x_1 - x_2 \\ \begin{vmatrix} x_3 & y_3 \\ x_4 & y_4 \end{vmatrix} & x_3 - x_4 \end{vmatrix}}{\begin{vmatrix} x_1 - x_2 & y_1 - y_2 \\ x_3 - x_4 & y_3 - y_4 \end{vmatrix}} \quad (1)$$

$$y = \frac{\begin{vmatrix} \begin{vmatrix} x_1 & y_1 \\ x_2 & y_2 \end{vmatrix} & \begin{vmatrix} y_1 & 1 \\ y_2 & 1 \end{vmatrix} \\ \begin{vmatrix} x_3 & y_3 \\ x_4 & y_4 \end{vmatrix} & \begin{vmatrix} y_3 & 1 \\ y_4 & 1 \end{vmatrix} \end{vmatrix}}{\begin{vmatrix} \begin{vmatrix} x_1 & 1 \\ x_2 & 1 \end{vmatrix} & \begin{vmatrix} y_1 & 1 \\ y_2 & 1 \end{vmatrix} \\ \begin{vmatrix} x_3 & 1 \\ x_4 & 1 \end{vmatrix} & \begin{vmatrix} y_3 & 1 \\ y_4 & 1 \end{vmatrix} \end{vmatrix}} = \frac{\begin{vmatrix} \begin{vmatrix} x_1 & y_1 \\ x_2 & y_2 \end{vmatrix} & y_1 - y_2 \\ \begin{vmatrix} x_3 & y_3 \\ x_4 & y_4 \end{vmatrix} & y_3 - y_4 \end{vmatrix}}{\begin{vmatrix} x_1 - x_2 & y_1 - y_2 \\ x_3 - x_4 & y_3 - y_4 \end{vmatrix}}. \quad (2)$$

In 3-D, let the two lines pass through points given by the vectors $(\mathbf{p}_1, \mathbf{q}_1)$ and $(\mathbf{p}_2, \mathbf{q}_2)$ and define

$$\mathbf{v}_1 = \frac{\mathbf{q}_1 - \mathbf{p}_1}{|\mathbf{q}_1 - \mathbf{p}_1|} \quad (3)$$

$$\mathbf{v}_2 = \frac{\mathbf{q}_2 - \mathbf{p}_2}{|\mathbf{q}_2 - \mathbf{p}_2|} \quad (4)$$

$$\mathbf{v}_{12} = \mathbf{v}_1 \times \mathbf{v}_2 \quad (5)$$

$$s_1 = \det(\mathbf{p}_2 - \mathbf{p}_1 \quad \mathbf{v}_2 \quad \mathbf{v}_{12}) \quad (6)$$

$$s_2 = \det(\mathbf{p}_2 - \mathbf{p}_1 \quad \mathbf{v}_1 \quad \mathbf{v}_{12}). \quad (7)$$

Then the point of intersection $\mathbf{p}$ of the two lines is given by

$$\mathbf{p} = \tfrac{1}{2}(\mathbf{p}_1 + \mathbf{v}_1 s_1 + \mathbf{p}_2 + \mathbf{v}_2 s_2) \quad (8)$$

(Glassner).

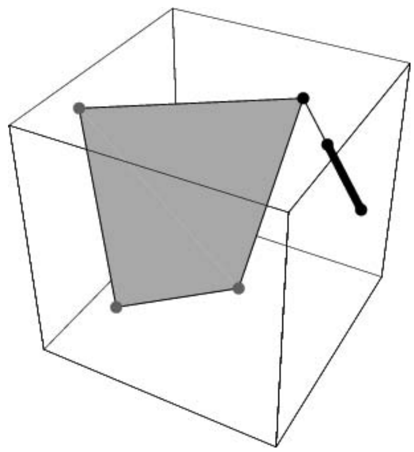
Line Line Picking

POINT-POINT DISTANCE–1-D

Line of Curvature



A curve on a surface whose tangents are always in the direction of PRINCIPAL CURVATURE. The equation of the lines of curvature can be written

$$\begin{vmatrix} g_{11} & g_{12} & g_{22} \\ b_{11} & b_{12} & b_{22} \\ du^2 & -du\, dv & dv^2 \end{vmatrix} = 0,$$

where g and b are the COEFFICIENTS of the first and second FUNDAMENTAL FORMS.

See also DUPIN'S THEOREM, FUNDAMENTAL FORMS, PRINCIPAL CURVATURES

Line-Plane Intersection

The PLANE determined by the points $\mathbf{x}_1$, $\mathbf{x}_2$, and $\mathbf{x}_3$ and the LINE passing through the points $\mathbf{x}_4$ and $\mathbf{x}_5$ intersect in a point which can be determined by solving the four simultaneous equations

$$\begin{vmatrix} x & y & z & 1 \\ x_1 & y_1 & z_1 & 1 \\ x_2 & y_2 & z_2 & 1 \\ x_3 & y_3 & z_3 & 1 \end{vmatrix} = 0 \tag{1}$$

$$x = x_4 + (x_4 - x_5)t \tag{2}$$

$$y = y_4 + (y_4 - y_5)t \tag{3}$$

$$z = z_4 + (z_4 - z_5)t \tag{4}$$

for x, y, z, and t, giving

$$t = \frac{\begin{vmatrix} 1 & 1 & 1 & 1 \\ x_1 & x_2 & x_3 & x_4 \\ y_1 & y_2 & y_3 & y_4 \\ z_1 & z_2 & z_3 & z_4 \end{vmatrix}}{\begin{vmatrix} 1 & 1 & 1 & 0 \\ x_1 & x_2 & x_3 & x_5 - x_4 \\ y_1 & y_2 & y_3 & y_5 - y_4 \\ z_1 & z_2 & z_3 & z_5 - z_4 \end{vmatrix}}. \tag{5}$$

This value can then be plugged back in to (2), (3), and (4) to give the point of intersection (x, y, z).

See also LINE, LINE-LINE INTERSECTION, PLANE

Line Segment

A closed interval corresponding to a FINITE portion of an infinite LINE. Line segments are generally labeled with two letters corresponding to their endpoints, say A and B, and then written AB. The length of the line segment is indicated with an overbar, so the length of the line segment AB would be written $\overline{AB}$.

Curiously, the number of points in a line segment (ALEPH-1) is equal to that in an entire 1-D SPACE (a LINE), and also to the number of points in an n-D SPACE, as first recognized by Georg Cantor.

Line Space

LIOUVILLE SPACE

L-Infinity-Norm

A VECTOR NORM defined for a VECTOR

$$\mathbf{x} = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{bmatrix},$$

with COMPLEX entries by

$$\|\mathbf{x}\|_\infty = \max_i |x_i|.$$

The vector norm $|\mathbf{x}|_\infty$ is implemented as `VectorNorm[`m`, Infinity]` in the *Mathematica* add-on package `LinearAlgebra‘MatrixMultiplication‘` (which can be loaded with the command `<<LinearAlgebra‘`).

See also L1-NORM, L2-NORM, VECTOR NORM

References

Gradshteyn, I. S. and Ryzhik, I. M. *Tables of Integrals, Series, and Products, 6th ed.* San Diego, CA: Academic Press, pp. 1114–125, 2000.

L-Infinity-Space

The SPACE called L^∞ (ell-infinity) generalizes the LP-SPACES to $p=\infty$. No integration is used to define them, and instead, the norm on L^∞ is given by the ESSENTIAL SUPREMUM.

More precisely,

$$\|f\|_\infty = \text{ess sup}|f|$$

is the norm which makes L^∞ a BANACH SPACE. It is the space of all essentially bounded functions. The space of bounded continuous functions is *not* DENSE in L^∞.

See also BANACH SPACE, COMPLETION, DENSE, ESSENTIAL SUPREMUM, LP-SPACE, L2-SPACE, MEASURE, MEASURABLE FUNCTION, MEASURE SPACE

Link

Formally, a link is one or more disjointly embedded CIRCLES in 3-space. More informally, a link is an assembly of KNOTS with mutual entanglements. Kuperberg (1994) has shown that a nontrivial KNOT or link in $\mathbb{R}^3$ has four COLLINEAR points (Eppstein). Doll and Hoste (1991) list POLYNOMIALS for oriented links of nine or fewer crossings.

A listing of the first few simple links follows, arranged by CROSSING NUMBER. The numbers of nontrivial 2-component links of 0, 1, 2, ... crossings are 1, 0, 1, 0, 1, 1, 3, 8, 16, 61, ... (Sloane's A048952). The numbers of nontrivial 3-component links of 6, 7, ... crossings are 3, 1, 10, 21, ... (Sloane's A048953). The number of nontrivial 4-component links of 8, 9, ... crossings are 3, 1, ...

00–2–1 02–2–1 04–2–1 05–2–1 06–2–1 06–2–2 06–2–3 07–2–1 07–2–2 07–2–3 07–2–4 07–2–5 07–2–6 07–2–7 07–2–8 08–2–1 08–2–2 08–2–3 08–2–4 08–2–5 08–2–6 08–2–7 08–2–8 08–2–9 08–2–0 08–2–1 08–2–2 08–2–3 08–2–4 08–2–5 08–2–6 09–2–1 09–2–2 09–2–3 09–2–4 09–2–5 09–2–6 09–2–7 09–2–8 09–2–9 09–2–0 09–2–1 09–2–2 09–2–3 09–2–4 09–2–5 09–2–6 09–2–7 09–2–8 09–2–9 09–2–0 09–2–1 09–2–2 09–2–3 09–2–4 09–2–5 09–2–6 09–2–7 09–2–8 09–2–9 09–2–0 09–2–1 09–2–2 09–2–3 09–2–4 09–2–5 09–2–6 09–2–7 09–2–8 09–2–9 09–2–0 09–2–1 09–2–2 09–2–3 09–2–4 09–2–5 09–2–6 09–2–7 09–2–8 09–2–9 09–2–0 09–2–1 09–2–2 09–2–3 09–2–4 09–2–5 09–2–6 09–2–7 09–2–8 09–2–9 09–2–0 09–2–1 06–3–1 06–3–2 06–3–3 07–3–1 08–3–1 08–3–2 08–3–3 08–3–4 08–3–5 08–3–6 08–3–7 08–3–8 08–3–9 08–3–0 09–3–1 09–3–2 09–3–3 09–3–4 09–3–5 09–3–6 09–3–7 09–3–8 09–3–9 09–3–0 09–3–1 09–3–2 09–3–3 09–3–4 09–3–5 09–3–6 09–3–7 09–3–8 09–3–9 09–3–0 09–3–1 08–4–1 08–4–2 08–4–3 09–4–1

Link (Simplicial Complex)

The set $\overline{\mathrm{St}}\,v - \mathrm{St}\,v$, where $\overline{\mathrm{St}}\,v$ is a CLOSED STAR and St v is a STAR, is called the link of v in a SIMPLICIAL COMPLEX K and is denoted Lkv (Munkres 1993, p. 11).

See also CLOSED STAR, SIMPLICIAL COMPLEX, STAR

Link Complement

KNOT COMPLEMENT

Link Diagram

A planar diagram depicting a LINK (or KNOT) as a sequence of segments with gaps representing undercrossings and solid lines overcrossings. In such a diagram, only two segments should ever cross at a single point. Link diagrams for the TREFOIL KNOT and FIGURE-OF-EIGHT KNOT are illustrated above.

Link Invariant

A link invariant is a function from the set of all LINKS to any other set such that the function does not change as the link is changed (up to isotopy). In other words, a link invariant always assigns the same value to equivalent links (although different knots may have the same link invariant). When the link has a single component and therefore generates to a KNOT, the invariant is called a KNOT INVARIANT.

See also KNOT, KNOT INVARIANT, LINK

Linkage

Sylvester, Kempe and Cayley developed the geometry associated with the theory of linkages in the 1870s. Kempe proved that every finite segment of an algebraic curve can be generated by a linkage in the manner of WATT'S CURVE.

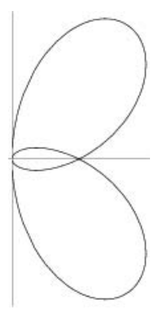
Linking Number

A LINK INVARIANT defined for a two-component oriented LINK as the sum of $+1$ crossings and -1 crossing over all crossings between the two links divided by 2. For components α and β,



$$Lk(\alpha,\ \beta) \equiv \tfrac{1}{2} \sum_{p \in \alpha \sqcap \beta} \epsilon(p),$$

where $\alpha \sqcap \beta$ is the set of crossings of α with β, and $\epsilon(p)$ is the sign of the crossing. The linking number of a splittable two-component link is always 0.

Linnik's Theorem

Let $p(d,\ a)$ be the smallest PRIME in the arithmetic progression $\{a + kd\}$ for k an INTEGER > 0. Let

$$p(d) \equiv \max p(d,\ a)$$

such that $1 \leq a < d$ and $(a,\ d) = 1$. Then there exists a $d_0 \geq 2$ and an $L\ >\ 1$ such that $p(d) < d^L$ for all $d > d_0$. L is known as LINNIK'S CONSTANT.

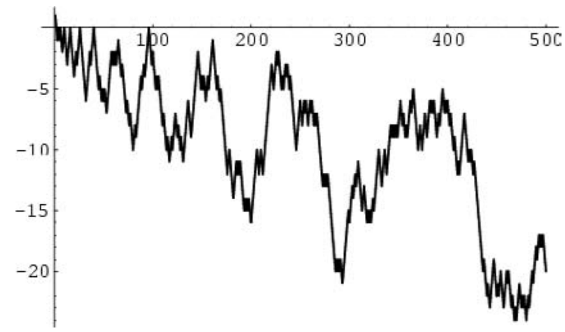
Liouville Function



The function

$$\lambda(n) = (-1)^{r(n)}, \tag{1}$$

where $r(n)$ is the number of not necessarily distinct PRIME FACTORS of n, with $r(1) = 0$. The first few values of $\lambda(n)$ are 1, -1, -1, 1, -1, 1, -1, -1, 1, 1, -1, -1, ... The Liouville function is connected with the RIEMANN ZETA FUNCTION by the equation

$$\frac{\zeta(2s)}{\zeta(s)} = \sum_{n=1}^{\infty} \frac{\lambda(n)}{n^s} \tag{2}$$

(Lehman 1960).

The CONJECTURE that the SUMMATORY FUNCTION

$$L(n) \equiv \sum_{k=1}^{n} \lambda(n) \tag{3}$$

satisfies $L(n) \leq 0$ for $n \geq 2$ is called the PÓLYA CONJECTURE and has been proved to be false. The first n for which $L(n) = 0$ are for $n = 2$, 4, 6, 10, 16, 26, 40, 96, 586, 906150256, ... (Sloane's A028488), and $n = 906150257$ is, in fact, the first counterexample to the PÓLYA CONJECTURE (Tanaka 1980). However, it is unknown if $L(x)$ changes sign infinitely often (Tanaka 1980). The first few values of $L(n)$ are 1, 0, -1, 0, -1, 0, -1, -2, -1, 0, -1, -2, -3, -2, -1, 0, -1, -2, -3, -4, ... (Sloane's A002819). $L(n)$ also satisfies

$$\sum_{n=1}^{x} L\left(\frac{x}{n}\right) = \lfloor \sqrt{x} \rfloor, \tag{4}$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION (Lehman 1960). Lehman (1960) also gives the formulas

$$\begin{aligned} L(x) = & \sum_{m=1}^{x/w} \mu(m) \\ & \times \left\{ \left\lfloor \sqrt{\frac{x}{m}} \right\rfloor - \sum_{k=1}^{v-1} \lambda(k) \left(\left\lfloor \frac{x}{km} \right\rfloor - \left\lfloor \frac{x}{mv} \right\rfloor \right) \right\} \\ & - \sum_{l=x/w-1}^{x/v} L\left(\frac{x}{l}\right) \sum_{\substack{m|l \\ m=1}}^{x/w} \mu(m) \end{aligned} \tag{5}$$

and

$$\begin{aligned} L(x) = & \sum_{k=1}^{g} M\left(\frac{x}{k^2}\right) + \sum_{l=1}^{x/g^2} \mu(l) \left\lfloor \sqrt{\frac{x}{l}} \right\rfloor - M\left(\frac{x}{g^2}\right) \\ & \times \left\lfloor \sqrt{\frac{x}{g^2}} \right\rfloor, \end{aligned} \tag{6}$$

where k, l, and m are variables ranging over the POSITIVE INTEGERS, $\mu(n)$ is the MÖBIUS FUNCTION, $M(x)$ is MERTENS FUNCTION, and v, w, and x are POSITIVE real numbers with $v < w < x$.

Liouville Measure

$$\prod_i dp_i\, dq_i,$$

where p_i and q_i are momenta and positions of particles.

See also LIOUVILLE'S PHASE SPACE THEOREM, PHASE SPACE

Liouville Number

A Liouville number is a TRANSCENDENTAL NUMBER which has very close RATIONAL NUMBER approximations. An IRRATIONAL NUMBER β is a Liouville number if, for any n, there exist an infinite number of pairs of INTEGERS p and q such that

$$0 < \left|\beta - \frac{p}{q}\right| < \frac{1}{q^n}.$$

LIOUVILLE'S CONSTANT is an example of a Liouville number. Mahler (1953) proved that π is not a Liouville number.

See also LIOUVILLE'S CONSTANT, LIOUVILLE'S APPROXIMATION THEOREM, ROTH'S THEOREM, TRANSCENDENTAL NUMBER

Liouville-Roth Constant

IRRATIONALITY MEASURE

Liouville's Approximation Theorem

For any ALGEBRAIC NUMBER x of degree $n \geq 2$, a RATIONAL approximation $x = p/q$ must satisfy

$$\left|x - \frac{p}{q}\right| > \frac{1}{q^{n+1}}$$

for sufficiently large q. Writing $r \equiv n+1$ leads to the definition of the IRRATIONALITY MEASURE of a given number. Apostol (1997) states the theorem in the slightly modified form that for all integers p and q with $q > 0$, there exists a positive constant $C(x)$ depending only on x such that

$$\left|x - \frac{p}{q}\right| > \frac{C(x)}{q^n}.$$

Liouville's Conformality Theorem

In SPACE, the only CONFORMAL MAPPINGS are inversions, SIMILARITY TRANSFORMATIONS, and CONGRUENCE TRANSFORMATIONS. Or, restated, every ANGLE-preserving transformation is a SPHERE-preserving transformation.

See also CONFORMAL MAP

Liouville's Conic Theorem

The lengths of the TANGENTS from a point P to a CONIC C are proportional to the CUBE ROOTS of the RADII OF CURVATURE of C at the corresponding points of contact.

See also CONIC SECTION

Liouville's Constant

$$L \equiv \sum_{n=1}^{\infty} 10^{-n!}$$
$$= 0.110001000000000000000001\ldots$$

(Sloane's A012245). Liouville's constant is a decimal fraction with a 1 in each decimal place corresponding to a FACTORIAL $n!$, and ZEROS everywhere else. Liouville (1844) constructed an infinite class of TRANSCENDENTAL NUMBERS using CONTINUED FRACTIONS, but the above number was the first decimal constant to be proven TRANSCENDENTAL (Liouville 1850). However, Cantor subsequently proved that "almost all" real numbers are in fact transcendental. Liouville's constant nearly satisfies

$$10x^6 - 75x^3 - 190x + 21 = 0,$$

but plugging $x = L$ into this equation gives $-0.0000000059\ldots$ instead of 0.

Liouville Space

Also known as LINE SPACE or "extended" HILBERT SPACE, it is the SET DIRECT PRODUCT of two HILBERT SPACES.

See also HILBERT SPACE, SET DIRECT PRODUCT

Liouville's Phase Space Theorem

States that for a nondissipative HAMILTONIAN SYSTEM, phase space density (the AREA between phase space contours) is constant. This requires that, given a small time increment dt,

$$q_1 = q(t_0 + dt) = q_0 + \frac{\partial H(q_0, p_0, t)}{\partial p_0} dt + \mathcal{O}(dt^2) \qquad (1)$$

$$p_1 \equiv p(t_0 + dt) = p_0 - \frac{\partial H(q_0, p_0, t)}{\partial q_0} dt + \mathcal{O}(dt^2), \qquad (2)$$

the JACOBIAN be equal to one:

$$\frac{\partial(q_1, p_1)}{\partial(q_0, p_0)} = \begin{vmatrix} \frac{\partial q_1}{\partial q_0} & \frac{\partial p_1}{\partial q_0} \\ \frac{\partial q_1}{\partial p_0} & \frac{\partial p_1}{\partial p_0} \end{vmatrix}$$

$$= \begin{vmatrix} 1 + \frac{\partial^2 H}{\partial q_0 \partial p_0} dt & -\frac{\partial^2 H}{\partial q_0^2} dt \\ \frac{\partial^2 H}{\partial p_0^2} dt & 1 - \frac{\partial^2 H}{\partial q_0 \partial p_0} dt \end{vmatrix} + \mathcal{O}(dt^2)$$

$$= 1 + \mathcal{O}(dt^2). \qquad (3)$$

Expressed in another form, the integral of the LIOUVILLE MEASURE,

$$\prod_{i=1}^{N} \int dp_i\, dq_i, \qquad (4)$$

is a constant of motion. SYMPLECTIC MAPS of HAMILTONIAN SYSTEMS must therefore be AREA preserving (and have DETERMINANTS equal to 1).

Liouville's Principle

Let F be a differential field with constant field K. For $f \in F$, suppose that the equation $g' = f$ (i.e., $g = \int f$) has a solution $g \in G$, where G is an elementary extension of F having the same constant FIELD K. Then there exist $v_0, v_1, ..., v_m \in F$ and constants $c_1, ..., c_m \in K$ such that

$$f = v_0' + \sum_{i=1}^{m} c_i \frac{v_i'}{v_i},$$

In other words, such that

$$\int f = v_0 + \sum_{i=1}^{m} c_i \ln v_i.$$

Lipschitz Function

A function f such that

$$|f(x) - f(y)| \leq C|x - y|$$

for all x and y, where C is a constant independent of x and y, is called a Lipschitz function. For example, any function with a bounded first derivative must be Lipschitz.

See also LIPSCHITZ CONDITION

Lissajous Curve

Lissajous curves are the family of curves described by the PARAMETRIC EQUATIONS

$$x(t) = A\cos(\omega_x t - \delta_x) \quad (1)$$

$$y(t) = B\cos(\omega_y t - \delta_y),. \quad (2)$$

sometimes also written in the form

$$x(t) = a\sin(nt + c) \quad (3)$$

$$y(t) = b\sin t. \quad (4)$$

They are sometimes known as BOWDITCH CURVES after Nathaniel Bowditch, who studied them in 1815. They were studied in more detail (independently) by Jules-Antoine Lissajous in 1857 (MacTutor Archive). Lissajous curves have applications in physics, astronomy, and other sciences. The curves close IFF ω_x/ω_y is RATIONAL.
Lissajous curves are a special case of the HARMONOGRAPH with damping constants $\beta_1 = \beta_2 = 0$.

See also HARMONOGRAPH

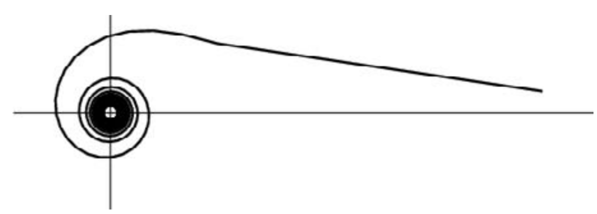
Lissajous Figure

LISSAJOUS CURVE

List



An DATA STRUCTURE consisting of an ordered SET of elements, each of which may be a number, another list, etc. A list is usually denoted $(a_1, a_2, ..., a_n)$ or $\{a_1, a_2, \ldots, a_n\}$, and may also be interpreted as a VECTOR. Multiplicity matters in a list, so (1, 1, 2) and (1, 2) are not equivalent.

See also MULTISET, QUEUE, SET, STACK, STRING, VECTOR

Little Moment Problem

MOMENT PROBLEM

Lituus

An ARCHIMEDEAN SPIRAL with $m = -2$, having polar equation

$$r^2\theta = a^2.$$

Lituus means a "crook," in the sense of a bishop's crosier. The lituus curve originated with Cotes in 1722. Maclaurin used the term lituus in his book *Harmonia Mensurarum* in 1722 (MacTutor Archive). The lituus is the locus of the point P moving such that the AREA of a circular SECTOR remains constant.

Lituus Inverse Curve

The INVERSE CURVE of the LITUUS is an ARCHIMEDEAN SPIRAL with $m = 2$, which is FERMAT'S SPIRAL.

See also ARCHIMEDEAN SPIRAL, FERMAT'S SPIRAL, LITUUS

LLL Algorithm

A LATTICE REDUCTION algorithm, named after discoverers Lenstra, Lenstra, and Lovasz (1982), that produces a lattice basis of "short" vectors. It was noticed by Lenstra *et al.* (1928) that the algorithm could be used to obtain factors of univariate polynomials, which amounts to the determination of INTEGER RELATIONS. However, this application of the algorithm, which later came to be one of its primary applications, was not stressed in the original paper.

The *Mathematica* command LatticeReduce[*matrix*] implements the LLL algorithm to perform LATTICE REDUCTION. *Mathematica*'s implementation requires the input to consist of rational numbers, so Rationalize may need to be called first.

More recently, other algorithms such as PSLQ, which can be significant faster than LLL, have been developed for finding INTEGER RELATIONS. PSLQ achieves its performance because of clever techniques that allow machine arithmetic to be used at many intermediate steps, whereas LLL must use moderate precision (although generally not as much as the HJLS ALGORITHM).

Lobachevsky-Bolyai-Gauss Geometry

HYPERBOLIC GEOMETRY

Lobachevsky's Formula

Given a point P and a LINE AB, draw the PERPENDICULAR through P and call it PC. Let PD be any other line from P which meets CB in D. In a HYPERBOLIC GEOMETRY, as D moves off to infinity along CB, then the line PD approaches the limiting line PE, which is said to be parallel to CB at P. The angle $\angle CPE$ which PE makes with PC is then called the ANGLE OF PARALLELISM for perpendicular distance x, and is given by

$$\prod(x) = 2\tan^{-1}(e^{-x}),$$

which is called Lobachevsky's formula.

See also ANGLE OF PARALLELISM, HYPERBOLIC GEOMETRY

References

Manning, H. P. *Introductory Non-Euclidean Geometry.* New York: Dover, p. 58, 1963.

Lobatto Quadrature

Also called RADAU QUADRATURE (Chandrasekhar 1960). A GAUSSIAN QUADRATURE with WEIGHTING FUNCTION $W(x) = 1$ in which the endpoints of the interval $[-1, 1]$ are included in a total of n ABSCISSAS, giving $r = n - 2$ free abscissas. ABSCISSAS are symmetrical about the origin, and the general FORMULA is

$$\int_{-1}^{1} f(x)\,dx = w_1 f(-1) + w_n f(1) + \sum_{i=2}^{n-1} w_i f(x_i). \qquad (1)$$

The free ABSCISSAS x_i for $i = 2, ..., n-1$ are the roots

of the POLYNOMIAL $P'_{n-1}(x)$, where $P(x)$ is a LEGENDRE POLYNOMIAL. The weights of the free abscissas are

$$w_i = -\frac{2n}{(1-x_i^2)P''_{n-1}(x_i)P'_m(x_i)} \tag{2}$$

$$= \frac{2}{n(n-1)[P_{n-1}(x_i)]^2}, \tag{3}$$

and of the endpoints are

$$w_{1,n} = \frac{2}{n(n-1)}. \tag{4}$$

The error term is given by

$$E = -\frac{n(n-1)^3 2^{2n-1}[(n-2)!]^4}{(2n-1)[(2n-1)!]^3} f^{(2n-2)}(\xi), \tag{5}$$

for $\xi \in (-1, 1)$. Beyer (1987) gives a table of parameters up to $n = 11$ and Chandrasekhar (1960) up to $n = 9$ (although Chandrasekhar's $\mu_{3,4}$ for $m = 5$ is incorrect).

n	x_i	w_i
3	0	1.33333
	$\pm$ 1	0.333333
4	$\pm$ 0.447214	0.833333
	$\pm$ 1	0.166667
5	0	0.711111
	$\pm$ 0.654654	0.544444
	$\pm$ 1	0.100000
6	$\pm$ 0.285232	0.554858
	$\pm$ 0.765055	0.378475
	$\pm$ 1	0.0666667

The ABSCISSAS and weights can be computed analytically for small n.

n	x_i	w_i
3	0	$\frac{4}{3}$
	± 1	$\frac{1}{3}$
4	$\pm\frac{1}{5}\sqrt{5}$	$\frac{1}{6}$
	± 1	$\frac{5}{6}$
5	0	$\frac{32}{45}$
	$\pm\frac{1}{7}\sqrt{21}$	$\frac{49}{90}$
	± 1	$\frac{1}{10}$

Local

A mathematical property P holds locally if P is true near every point. In many different areas of mathematics, this notion is very useful. For instance, the sphere, and more generally a MANIFOLD, is locally Euclidean. For every point on the sphere, there is a NEIGHBORHOOD which is the same as a piece of EUCLIDEAN SPACE.

The description of local as "near every point" has a different interpretation in algebra. For instance, given a RING R and a PRIME IDEAL p, there is the LOCAL RING R_p, which often is simpler to study. It is possible to understand the original ring better by patching together the information from the local rings.

What ties all the notions of local together is the concept of a topology, a collection of open sets. For a SUBMANIFOLD of Euclidean space, or for the set of ideals of a ring, the topology is chosen as is appropriate.

A property P holds locally on a TOPOLOGICAL SPACE if every point has a NEIGHBORHOOD on which P holds. This concept is useful on any topological space.

See also GLOBAL, LOCAL FIELD, LOCAL RING, MANIFOLD, TOPOLOGICAL SPACE

Local Cell

The POLYHEDRON resulting from letting each SPHERE in a SPHERE PACKING expand uniformly until it touches its neighbors on flat faces.

See also LOCAL DENSITY, SPHERE PACKING

Local Class Field Theory

The study of NUMBER FIELDS by embedding them in a LOCAL FIELD is called local class field theory. Information about an equation in a LOCAL FIELD may give information about the equation in a GLOBAL FIELD, such as the rational numbers or a NUMBER FIELD (e.g., the HASSE PRINCIPLE).

Local class field theory is termed "local" because the local fields are LOCALIZED at a PRIME IDEAL in the RING of ALGEBRAIC INTEGERS. The methods of using CLASS FIELDS have developed over the years, from the LEGENDRE SYMBOL, to the CHARACTERS of ABELIAN EXTENSIONS of a number field, and is applied to LOCAL FIELDS.

See also ABELIAN EXTENSION, CLASS FIELD, FIELD, GLOBAL FIELD, HASSE PRINCIPLE, LOCAL FIELD, NUMBER FIELD, UNIQUE FACTORIZATION

Weil, A. *Basic Number Theory.* New York:Springer-Verlag, Chapter VII, 1974.

Local Degree

The degree of a VERTEX of a GRAPH is the number of EDGES which touch the VERTEX, also called the LOCAL DEGREE. The VERTEX degree of a point A in a GRAPH, denoted $\rho(A)$, satisfies

$$\sum_{i=1}^{n} \rho(A_i) = 2E,$$

where E is the total number of EDGES. Directed graphs have two types of degrees, known as the INDEGREE and OUTDEGREE.

See also INDEGREE, OUTDEGREE

Local Density

Let each SPHERE in a SPHERE PACKING expand uniformly until it touches its neighbors on flat faces. Call the resulting POLYHEDRON the LOCAL CELL. Then the local density is given by

$$\rho \equiv \frac{V_{\text{sphere}}}{V_{\text{local cell}}}.$$

When the LOCAL CELL is a regular DODECAHEDRON, then

$$\rho_{\text{dodecahedron}} = \frac{\pi\sqrt{5+\sqrt{5}}}{15\sqrt{10}(\sqrt{5}-2)} = 0.7547\ldots.$$

See also LOCAL CELL, LOCAL DENSITY CONJECTURE, SPHERE PACKING

Local Density Conjecture

The CONJECTURE that the maximum LOCAL DENSITY is given by $\rho_{\text{dodecahedron}}$.

See also DODECAHEDRAL CONJECTURE, LOCAL DENSITY

Local Extremum

A LOCAL MINIMUM or LOCAL MAXIMUM.

See also EXTREMUM, GLOBAL EXTREMUM

Local Field

A FIELD which is complete with respect to a discrete VALUATION is called a local field if its FIELD of RESIDUE CLASSES is FINITE. The HASSE PRINCIPLE is one of the chief applications of local field theory.

See also FUNCTION FIELD, HASSE PRINCIPLE, NUMBER FIELD, VALUATION

References

Local-Global Principle

HASSE PRINCIPLE

Local Group Theory

The study of a FINITE GROUP G using the LOCAL SUBGROUPS of G. Local group theory plays a critical role in the CLASSIFICATION THEOREM.

See also SYLOW THEOREMS

Local Maximum

The largest value of a set, function, etc., within some local neighborhood.

See also Global Maximum, Local Minimum, Maximum, Peano Surface

Local Minimum

The smallest value of a set, function, etc., within some local neighborhood.

See also Global Minimum, Local Maximum, Minimum

Local Ring

A Noetherian ring R with a Jacobson radical which has only a single maximal ideal. One property of a local ring R is that the subset $R-m$ is precisely the set of units, where m is the maximal ideal. This follows because, in a ring, any nonunit belongs to at least one maximal ideal.

See also Jacobson Radical, Maximal Ideal, Noetherian Ring, Residue Field, Unit (Ring)

Iyanaga, S. and Kawada, Y. (Eds.). "Local Rings." §281D in *Encyclopedic Dictionary of Mathematics.* Cambridge, MA: MIT Press, pp. 890–91, 1980.

Local Subgroup

A normalizer of a nontrivial Sylow p-subgroup of a group G.

See also Local Group Theory

Local Surface

Patch

Locally Compact

A topological space X is locally compact if every point has a neighborhood which is itself contained in a compact set. Many familiar topological spaces are locally compact, including the Euclidean space. Of course, any compact set is locally compact. Some common spaces are not locally compact, such as infinite dimensional Banach spaces. For instance, the L2-space of square integrable functions is not locally compact.

See also Compact Set, Locally Compact Group, Neighborhood, Topological Space

Locally Convex Space

Locally Pathwise-Connected

Locally Finite Complex

A simplicial complex K is said to be locally finite if each vertex of K belongs only to finitely many simplices of K.

References

Munkres, J. R. *Elements of Algebraic Topology.* Perseus Press, 1993.

Locally Finite Space

A locally finite space is one for which every point of a given space has a neighborhood that meets only finitely many elements of the cover.

Locally Integrable

A function is called locally integrable if, around every point in the domain, there is a neighborhood on which the function is integrable. The space of locally integrable functions is denoted L^1_{loc}. Any integrable function is also locally integrable. One possibility for a nonintegrable function which is locally integrable is if it does not decay at infinity. For instance, $f(x)=1$ is locally integrable on $\mathbb{R}$, as is any continuous function.

See also Frechet Space, Integrable, Lebesgue Integrable, L1-Space

Locally Pathwise-Connected

A space X is locally pathwise-connected if for every neighborhood around every point in X, there is a smaller, pathwise-connected neighborhood.

See also Arcwise-Connected, Pathwise-Connected

Locally Pathwise-Connected Space

A space X is locally pathwise-connected if for every neighborhood around every point in X, there is a smaller, pathwise-connected neighborhood.

Lochs' Theorem

For a real number $x \in (0, 1)$, let m be the number of terms in the convergent to a continued fraction that are required to represent n decimal places of x. Then for almost all x,

$$\lim_{n\to\infty} \frac{m}{n} = \frac{6 \ln 2 \ln 10}{\pi^2} = 0.97027014\ldots$$

(Lochs 1964). Therefore, the continued fraction is only slightly more efficient at representing real numbers than is the decimal expansion. The set of x for which this statement does not hold is of measure 0.

Loculus of Archimedes

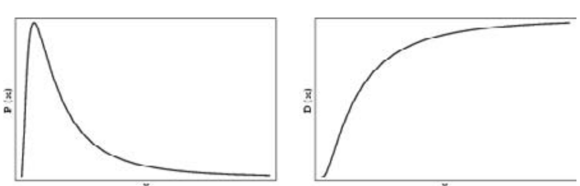
STOMACHION

Locus

The set of all points (usually forming a curve or surface) satisfying some condition. For example, the locus of points in the plane equidistant from a given point is a CIRCLE, and the set of points in 3-space equidistant from a given point is a SPHERE.

References

Casey, J. *A Sequel to the First Six Books of the Elements of Euclid, Containing an Easy Introduction to Modern Geometry with Numerous Examples, 5th ed., rev. enl.* Dublin: Hodges, Figgis, & Co., pp. 5–, 1888.



Log

COMMON LOGARITHM, LOGARITHM, NATURAL LOGARITHM

Log Likelihood Procedure

A method for testing NESTED HYPOTHESES. To apply the procedure, given a specific model, calculate the LIKELIHOOD of observing the actual data. Then compare this likelihood to a nested model (i.e., one in which fewer parameters are allowed to vary independently).

Log Normal Distribution

A CONTINUOUS DISTRIBUTION in which the LOGARITHM of a variable has a NORMAL DISTRIBUTION. It is a general case of GILBRAT'S DISTRIBUTION, to which the log normal distribution reduces with $S=1$ and $M=0$. The probability density and cumulative distribution functions for the log normal distribution are

$$P(x)=\frac{1}{Sx\sqrt{2\pi}}\,e^{-(\ln x-M)^2/(2S^2)} \tag{1}$$

$$D(x)=\frac{1}{2}\left[1+\operatorname{erf}\left(\frac{\ln x-M}{S\sqrt{2}}\right)\right], \tag{2}$$

where $\operatorname{erf}(x)$ is the ERF function. This distribution is normalized, since letting $y\equiv\ln x$ gives $dy=dx/x$ and $x=e^y$, so

$$\int_0^\infty P(x)\,dx=\frac{1}{S\sqrt{2\pi}}\int_{-\infty}^{\infty}e^{-(y-M)^2/2s^2}\,dy=1. \tag{3}$$

The RAW MOMENTS are

$$\mu_1'=e^{M+S^2/2} \tag{4}$$

$$\mu_2'=e^{2(M+S)^2} \tag{5}$$

$$\mu_3'=e^{3M+9S^2/2} \tag{6}$$

$$\mu_4'=e^{4M+8S^2}, \tag{7}$$

and the CENTRAL MOMENTS are

$$\mu_2=e^{2M+S^2}(e^{S^2}-1) \tag{8}$$

$$\mu_3=e^{3M+3S^2/2}(e^{S^2}-1)^2(e^{S^2}+2) \tag{9}$$

$$\mu_4=e^{4M+2S^2}(e^{S^2}-1)^2(e^{4S2}+2e^{3S^2}+3e^{2S^2}-3). \tag{10}$$

Therefore, the MEAN, VARIANCE, SKEWNESS, and KURTOSIS are given by

$$\mu=e^{M+S^2/2} \tag{11}$$

$$\sigma^2=e^{S^2+2M}(e^{S^2}-1) \tag{12}$$

$$\gamma_1=\sqrt{e^{S^2}-1}\,(2+e^{S^2}) \tag{13}$$

$$\gamma_2=e^{4S^2}+2e^{3S^2}+3e^{2S^2}-6. \tag{14}$$

These can be found by direct integration

$$\begin{aligned}\mu&=\frac{1}{S\sqrt{2\pi}}\int_0^\infty e^{-(\ln x-M)^2/(2S^2)}\,dx\\&=\frac{1}{S\sqrt{2\pi}}\int_{-\infty}^{\infty}e^{-(-y-M)^2/2S^2}e^y\,dy\\&=e^{M+S^2/2},\end{aligned} \tag{15}$$

and similarly for σ^2.

Examples of variates which have approximately log normal distributions include the size of silver particles in a photographic emulsion, the survival time of bacteria in disinfectants, the weight and blood pressure of humans, and the number of words written in sentences by George Bernard Shaw.

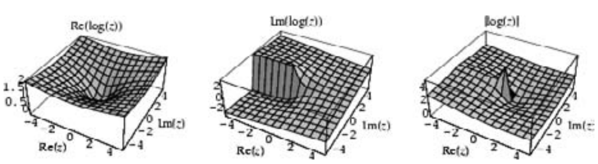
Logarithm

The logarithm $\log_b x$ for a BASE b and a number x is defined to be the INVERSE FUNCTION of taking x to the POWER b. Therefore, for any x and b,

$$x = b^{\log_b x}, \tag{1}$$



or equivalently,

$$x = \log_b(b^x). \tag{2}$$

Whereas power of trigonometric functions are denoted using notations like $\sin^k x$, $\ln^k x$ is less commonly used in favor of the notation $(\ln x)^k$.

For any BASE, the logarithm function has a SINGULARITY at $x = 0$. In the above plot, the solid curve is the logarithm to BASE e (the NATURAL LOGARITHM), and the dotted curve is the logarithm to BASE 10 (LOG).

Logarithms are used in many areas of science and engineering in which quantities vary over a large range. For example, the decibel scale for the loudness of sound, the Richter scale of earthquake magnitudes, and the astronomical scale of stellar brightnesses are all logarithmic scales.

The logarithm can also be defined for COMPLEX arguments, as shown above. If the logarithm is taken as the forward function, the function taking the BASE to a given POWER is then called the ANTILOGARITHM.

For $x = \log N$, $\lfloor x \rfloor$ is called the CHARACTERISTIC and $x - \lfloor x \rfloor$ is called the MANTISSA. Division and multiplication identities follow from these

$$xy = b^{\log_b x} b^{\log_b y} = b^{\log_b x + \log_b y}, \tag{3}$$

from which it follows that

$$\log_b(xy) = \log_b x + \log_b y \tag{4}$$

$$\log_b\left(\frac{x}{y}\right) = \log_b x - \log_b y \tag{5}$$

$$\log_b x^n = n \log_b x. \tag{6}$$

There are a number of properties which can be used to change from one logarithm BASE to another

$$a = a^{\log_a b / \log_a b} = (a^{\log_a b})^{1/\log_a b} = b^{1/\log_a b} \tag{7}$$

$$\log_b a = \frac{1}{\log_a b} \tag{8}$$

$$\log_b x = \log_b\left(y^{\log_y x}\right) = \log_y x \log_b y \tag{9}$$

$$\log_b x = \frac{\log_n x}{\log_n b} \tag{10}$$

$$a^x = b^{x/\log_a b} = b^{x \log_b a}. \tag{11}$$

The logarithm BASE E is called the NATURAL LOGARITHM and is denoted $\ln x$ (LN). The logarithm BASE 10 is denoted $\log x$ (LOG), (although mathematics texts often use $\log x$ to mean $\ln x$). The logarithm BASE 2 is denoted $\lg x$ (LG).

An interesting property of logarithms follows from looking for a number y such that

$$\log_b(x+y) = -\log_b(x-y) \tag{12}$$

$$x + y = \frac{1}{x-y} \tag{13}$$

$$x^2 - y^2 = 1 \tag{14}$$

$$y = \sqrt{x^2 - 1}, \tag{15}$$

so

$$\log_b\left(x + \sqrt{x^2-1}\right) = -\log_b\left(x - \sqrt{x^2-1}\right). \tag{16}$$

Numbers OF THE FORM $\log_a b$ are IRRATIONAL if a and b are INTEGERS, one of which has a PRIME factor which the other lacks. A. Baker made a major step forward in TRANSCENDENTAL NUMBER theory by proving the transcendence of sums of numbers OF THE FORM $\alpha \ln \beta$ for α and β ALGEBRAIC NUMBERS.

Logarithmic Binomial Formula

LOGARITHMIC BINOMIAL THEOREM

Logarithmic Binomial Theorem

For all integers n and $|x| < a$,

$$\lambda_n^{(t)}(x+a) = \sum_{k=0}^{\infty} \left\lfloor {n \atop k} \right\rceil \lambda_{n-k}^{t}(a) x^k,$$

where $\lambda_n^{(t)}$ is the HARMONIC LOGARITHM and $\left\lfloor {n \atop k} \right\rceil$ is a ROMAN COEFFICIENT. For $t = 0$, the logarithmic binomial theorem reduces to the classical BINOMIAL THEOREM for POSITIVE n, since $\lambda_1^{(0)}(a) - c^{n-k}$ for $n \geq k$, $\lambda_{n-k}^{(0)}(a) = 0$ for $n < k$, and $\left\lfloor {n \atop k} \right\rceil = \binom{n}{k}$ when $n \geq k \geq 0$. Similarly, taking $t = 1$ and $n < 0$ gives the NEGATIVE BINOMIAL SERIES. Roman (1992) gives expressions obtained for the case $t = 1$ and $n \geq 0$ which are not obtainable from the BINOMIAL THEOREM.

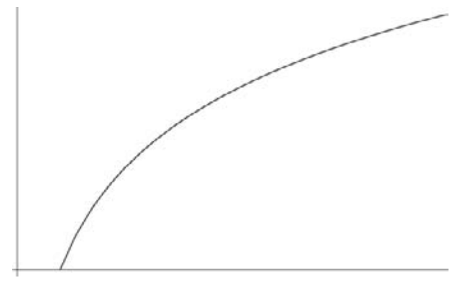
Logarithmic Derivative

The logarithmic derivative of a function f is defined as the DERIVATIVE of the LOGARITHM of a function. For example, the DIGAMMA FUNCTION is defined as the logarithmic derivative of the GAMMA FUNCTION,



$$\Psi(z) = \frac{d}{dz} \ln \Gamma(z).$$

See also DERIVATIVE, DIGAMMA FUNCTION, LOGARITHM, POLYGAMMA FUNCTION

References

Zwillinger, D. (Ed.). "Logarithmic Derivative." §6.11.8 in *CRC Standard Mathematical Tables and Formulae.* Boca Raton, FL: CRC Press, p. 496, 1995.

Logarithmic Distribution

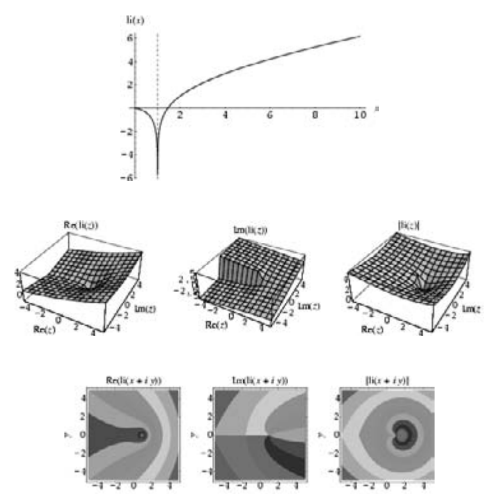
A CONTINUOUS DISTRIBUTION for a variate $x \in [a, b]$ with probability function

$$P(x) = \frac{\ln x}{b(\ln b - 1) - a(\ln a - 1)} \tag{1}$$

and distribution function

$$D(x) = \frac{a(1 - \ln a) - x(1 - \ln x)}{a(1 - \ln a) - b(1 - \ln b)}. \tag{2}$$

The moments about zero are given by



$$\mu'_n = \frac{a^{n+1}[1 - (n+1)\ln a] - b^{n+1}[1 - (n+1)\ln b]}{(n+1)^2[a(1 - \ln a) - b(1 - \ln b)]}, \tag{3}$$

giving MEAN

$$\mu = \frac{a^2(1 - 2\ln a) - b^2(1 - 2\ln b)}{4[a(1 - \ln a) - b(1 - \ln b)]}. \tag{4}$$

The VARIANCE, SKEWNESS, and KURTOSIS are complicated expressions involving the μ'_n.

Logarithmic Integral

The logarithmic integral is defined by

$$\mathrm{li}(x) \equiv \int_0^x \frac{du}{\ln u}. \tag{1}$$

This function is implemented in *Mathematica* as `LogIntegral[x]`. The logarithmic integral obeys the identity

$$\mathrm{li}(x^m) = \gamma + \ln \ln x - lnm + \sum_{n=1}^{\infty} \frac{(\ln x)^n}{n \cdot n! m^n} \tag{2}$$

(Bromwich and MacRobert 1991, p. 334; Hardy 1999, p. 25).

The form of this function appearing in the PRIME NUMBER THEOREM is defined so that $\mathrm{Li}(2) = 0$:

$$\mathrm{Li}(x) \equiv \int_2^x \frac{du}{\ln u} \tag{3}$$

$$= \mathrm{li}(x) - \mathrm{li}(2) \approx \mathrm{li}(x) - 1.04516 \tag{4}$$

$$= \mathrm{ei}(\ln x), \tag{5}$$

where $\mathrm{ei}(x)$ is the EXPONENTIAL INTEGRAL. (Note that the NOTATION $\mathrm{Li}_n(z)$ is also used for the POLYLOGARITHM.) Nielsen (1965, pp. 3 and 11) showed and Ramanujan independently discovered (Berndt 1994) that

$$\int_\mu^x \frac{dt}{\ln t} = \gamma + \ln \ln x + \sum_{k=1}^{\infty} \frac{(\ln x)^k}{k! k}, \tag{6}$$

where γ is the EULER-MASCHERONI CONSTANT and μ is SOLDNER'S CONSTANT. Another FORMULA due to Ramanujan which converges more rapidly is

$$\int_\mu^x \frac{dt}{\ln t} = \gamma + \ln \ln x$$

$$+ \sqrt{x} \sum_{n=0}^{\infty} \frac{(-1)^{n-1} (\ln x)^n}{n! 2^{n-1}} \sum_{k=0}^{[(n-1)/2]} \frac{1}{2k+1} \tag{7}$$

(Berndt 1994).

Logarithmic Spiral

A curve whose equation in POLAR COORDINATES is

given by

$$r = ae^{b\theta}, \tag{1}$$

where r is the distance from the ORIGIN, θ is the angle from the X-AXIS, and a and b are arbitrary constants. The logarithmic spiral is also known as the GROWTH SPIRAL, EQUIANGULAR SPIRAL, and SPIRA MIRABILIS. It can be expressed parametrically using

$$\cos\theta = \frac{1}{\sqrt{1-\tan^2\theta}} = \frac{1}{\sqrt{1+\frac{y^2}{x^2}}} = \frac{x}{\sqrt{x^2+y^2}} = \frac{x}{r}, \tag{2}$$

which gives

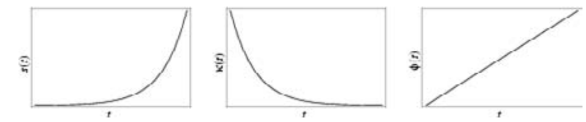
$$x = r\cos\theta = a\cos\theta e^{b\theta} \tag{3}$$

$$y = x\tan\theta = r\sin\theta = a\sin\theta e^{b\theta}. \tag{4}$$

The logarithmic spiral can be constructed from equally spaced rays by starting at a point along one ray, and drawing the perpendicular to a neighboring ray. As the number of rays approached infinity, the sequence of segments approaches the smooth logarithmic spiral (Hilton *et al.* 1997, pp. 2–).

The logarithmic spiral was first studied by Descartes in 1638 and Jakob Bernoulli. Bernoulli was so fascinated by the spiral that he had one engraved on his tombstone (although the engraver did not draw it true to form) together with the words "eadem mutata resurgo" ("I shall arise the same though changed"rpar;. Torricelli worked on it independently and found the length of the curve (MacTutor Archive).

The rate of change of RADIUS is



$$\frac{dr}{d\theta} = abe^{b\theta} = br, \tag{5}$$

and the ANGLE between the tangent and radial line at the point (r, θ) is

$$\psi = \tan^{-1}\left(\frac{r}{\frac{dr}{d\theta}}\right) = \tan^{-1}\left(\frac{1}{b}\right) = \cot^{-1}b. \tag{6}$$

So, as $b \to 0$, $\psi \to \pi/2$ and the spiral approaches a CIRCLE.

If P is any point on the spiral, then the length of the spiral from P to the origin is finite. In fact, from the point P which is at distance r from the origin measured along a RADIUS vector, the distance from P to the POLE along the spiral is just the ARC LENGTH. In addition, any RADIUS from the origin meets the spiral at distances which are in GEOMETRIC PROGRESSION (MacTutor Archive).

The ARC LENGTH, CURVATURE, and TANGENTIAL ANGLE of the logarithmic spiral are

$$s = \int ds = \int \sqrt{x'^2 + y'^2}\, dt = \frac{a\sqrt{1+b^2}}{b} e^{b\theta}$$

$$= \frac{r\sqrt{1+b^2}}{b} \tag{7}$$

$$\kappa = \frac{x'y'' - y'x''}{(x'^2 + y'^2)^{3/2}} = \left(a\sqrt{1+b^2}\, e^{b\theta}\right)^{-1} \tag{8}$$

$$\phi = \int \kappa(s)\, ds = \theta. \tag{9}$$

The CESÀRO EQUATION is

$$\kappa = \frac{1}{bs}. \tag{10}$$

On the surface of a SPHERE, the analog is a LOXODROME. This SPIRAL is related to FIBONACCI NUMBERS and the GOLDEN RATIO.

Logarithmic Spiral Caustic Curve

The CAUSTIC of a LOGARITHMIC SPIRAL, where the pole is taken as the RADIANT POINT, is an equal LOGARITHMIC SPIRAL.

Logarithmic Spiral Evolute

In POLAR COORDINATES $r = r(\theta)$, the RADIUS OF CURVATURE is given by

$$R = \frac{(r^2 + r_\theta^2)^{3/2}}{r^2 + 2r^2 r_\theta^2 - r r_{\theta\theta}}, \tag{1}$$

so plugging in the equation of the LOGARITHMIC SPIRAL and its derivatives

$$r = ae^{b\theta} \tag{2}$$

$$r_\theta = abe^{b\theta} \tag{3}$$

$$r_{\theta\theta} = ab^2 e^{b\theta} \tag{4}$$

gives

$$R = a\sqrt{1+b^2}\, e^{b\theta}. \tag{5}$$

To find the VELOCITY VECTOR, compute

$$\begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} ae^{b\theta} & \cos\theta \\ ae^{b\theta} & \sin\theta \end{bmatrix}$$

$$\begin{bmatrix} x' \\ y' \end{bmatrix} = \begin{bmatrix} abe^{b\theta} & \cos\theta - ae^{b\theta}\sin\theta \\ abe^{b\theta} & \sin\theta + ae^{b\theta}\cos\theta \end{bmatrix}$$

$$= ae^{b\theta} \begin{bmatrix} b\cos\theta - \sin\theta \\ b\sin\theta + \cos\theta \end{bmatrix}, \tag{6}$$

so

$$|\mathbf{r}'| = ae^{b\theta}\sqrt{(b\cos\theta - \sin\theta)^2 + (b\sin\theta + \cos\theta)^2}$$

$$= ae^{b\theta}\sqrt{1+b^2}, \tag{7}$$

and the TANGENT VECTOR is given by

$$\hat{\mathbf{T}} = \frac{\mathbf{r}'}{|\mathbf{r}'|} = \frac{1}{ae^{b\theta}\sqrt{1+b^2}} \begin{bmatrix} ae^{b\theta}\cos\theta \\ ae^{b\theta}\sin\theta \end{bmatrix}$$

$$= \frac{1}{\sqrt{1+b^2}} \begin{bmatrix} \cos\theta \\ \sin\theta \end{bmatrix}. \tag{8}$$

The coordinates of the EVOLUTE are therefore

$$\xi = -abe^{b\theta}\sin\theta \tag{9}$$

$$\eta = -abe^{b\theta}\cos\theta. \tag{10}$$

Therefore, the EVOLUTE is another logarithmic spiral with $a' \equiv ab$, as first shown by Johann Bernoulli.

In some cases, the EVOLUTE is identical to the original, as can be demonstrated by making the substitution to the new variable

$$\theta \equiv \phi - \tfrac{1}{2}\pi \pm 2n\pi. \tag{11}$$

Then the above equations become

$$\xi = -abe^{b(\phi - \pi/2 \pm 2n\pi)}\sin(\phi - \pi/2 \pm 2n\pi)$$

$$= abe^{b\phi}e^{b(-\pi/2 \pm 2n\pi)}\cos\phi \tag{12}$$

$$\eta = abe^{b(\phi - \pi/2 \pm 2n\pi)}\cos(\phi - \pi/2 \pm 2n\pi)$$

$$= abe^{b\phi}e^{b(-\pi/2 \pm 2n\pi)}\sin\phi, \tag{13}$$

which are equivalent to the form of the original equation if

$$be^{b\left(-\frac{1}{2}\pi \pm 2n\pi\right)} = 1 \tag{14}$$

$$\ln b + b\left(-\tfrac{1}{2}\pi \pm 2n\pi\right) = 0 \tag{15}$$

$$\frac{\ln b}{b} = \tfrac{1}{2}\pi \mp 2n\pi = -\left(2n - \tfrac{1}{2}\right)\pi, \tag{16}$$

where only solutions with the minus sign in $\mp$ exist. Solving gives the values summarized in the following table.

n	b_n	$\psi = \cot^{-1} b_n$

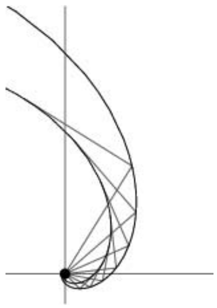
Logarithmic Spiral Inverse Curve



The INVERSE CURVE of the LOGARITHMIC SPIRAL

$$r = e^{a\theta}$$

with INVERSION CENTER at the origin and inversion radius k is the LOGARITHMIC SPIRAL

$$r = ke^{-a\theta}.$$

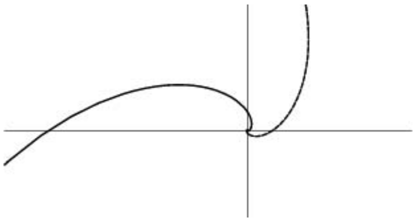
Logarithmic Spiral Pedal Curve

The PEDAL CURVE of a LOGARITHMIC SPIRAL with parametric equation

$$f = e^{at} \cos t \quad (1)$$

$$g = e^{at} \sin t \quad (2)$$

for a PEDAL POINT at the pole is an identical LOGARITHMIC SPIRAL



$$x = \frac{(a \sin t + \cos t)e^{at}}{1 + a^2} \quad (3)$$

$$y = \frac{(\sin t - a \cos t)e^{at}}{1 + a^2} \quad (4)$$

so

$$r = \sqrt{x^2 + y^2} = \frac{e^{at}}{\sqrt{1 + a^2}}. \quad (5)$$

Logarithmic Spiral Radial Curve

The RADIAL CURVE of the LOGARITHMIC SPIRAL is another LOGARITHMIC SPIRAL.

Logarithmic Transform

The inverse transform

$$\sum_{n=1}^{\infty} \frac{a_n x^n}{n!} = \ln\left(1 + \sum_{n=1}^{\infty} \frac{b_n x^n}{n!}\right)$$

of the EXPONENTIAL TRANSFORM

$$1 + \sum_{n=1}^{\infty} \frac{b_n x^n}{n!} = \exp\left(\sum_{n=1}^{\infty} \frac{a_n x^n}{n!}\right)$$

which relate sequences a_1, a_2, ... and b_1, b_2, ...

GAMMA FUNCTION

Logic

The formal mathematical study of the methods, structure, and validity of mathematical deduction and proof.

In Hilbert's day, formal logic sought to devise a complete, consistent formulation of mathematics

such that propositions could be formally stated and proved using a small number of symbols with WELL DEFINED meanings. The difficulty of formal logic was demonstrated in the monumental *Principia Mathematica* (1925) of Whitehead and Russell's , in which hundred of pages of symbols were required before the statement $1+1=2$ could be deduced. In 1931, Gödel unexpectedly showed that Hilbert's goal to be impossible, and this proved only the first of a number of difficult and counterintuitive results which have since been demonstrated.

A very simple form of logic is the study of "TRUTH TABLES" and digital logic circuits in which one or more outputs depend on a combination of circuit elements (AND, OR, NAND, NOR, NOT, XOR, etc.; "gates") and the input values. In such a circuit, values at each point can take on values of only TRUE (1) or FALSE (0). DE MORGAN'S DUALITY LAW is a useful principle for the analysis and simplification of such circuits.

A generalization of this simple type of logic in which possible values are TRUE, FALSE, and "undecided" is called THREE-VALUED LOGIC. A further generalization called FUZZY LOGIC treats "truth" as a continuous quantity ranging from 0 to 1.

von Seggern, D. *CRC Standard Curves and Surfaces.* Boca Raton, FL: CRC Press, p. 250, 1993.

Logistic Equation

The logistic equation (sometimes called the VERHULST MODEL since it was first published in 1845 by the Belgian P.-F. Verhulst) is defined by

$$x_{n+1} = rx_n(1-x_n), \tag{1}$$

where r (sometimes also denoted μ) is a POSITIVE constant (the "biotic potential"). Let an initial point x_0 lie in the interval [0, 1]. Now find appropriate conditions on r which keep points in the interval. The maximum value x_{n+1} can take is found from

$$\frac{dx_{n+1}}{dx_n} = r(1-2x_n) = 0, \tag{2}$$

so the largest value of x_{n+1} occurs for $x_n = 1/2$. Plugging this in, $\max(x_{n+1}) = r/4$. Therefore, to keep the MAP in the desired region, we must have $r \in (0,\ 4]$. The JACOBIAN is

$$J = \left|\frac{dx_{n+1}}{dx_n}\right| = |r(1-2x_n)|, \tag{3}$$

and the MAP is stable at a point x_0 if $J(x_0) < 1$.

Now find the FIXED POINTS of the MAP, which occur when $x_{n+1} = x_n$. For convenience, drop the n subscript on x_n

$$f(x) = rx(1-x) = x \tag{4}$$

$$x[1-r(1-x)] = x(1-r+rx) = rx[x-(1-r^{-1})] = 0, \tag{5}$$

so the FIXED POINTS are $x_1^{(1)} = 0$ and $x_2^{(1)} = 1 - r^{-1}$.

An interesting thing happens if a value of r greater than 3 is chosen. The map becomes unstable and we get a PITCHFORK BIFURCATION with two stable orbits of period two corresponding to the two stable FIXED POINTS of $f^2(x)$. The fixed points of order two must satisfy $x_{n+2} = x_n$, so

$$\begin{aligned} x_{n+2} &= rx_{n+1}(1-x_{n+1}) \\ &= r[rx_n(1-x_n)][1-rx_n(1-x_n)] \\ &= r^2x_n(1-x_n)(1-rx_n+rx_n^2) = x_n. \end{aligned} \tag{6}$$

For convenience, drop the n subscripts and rewrite

$$x\{r^2[1-x(1+r)+2rx^2-rx^3]-1\} = 0 \tag{7}$$

$$x[-r^3x^3+2r^3x^2-r^2(1+r)x+(r^2-1)] = 0 \tag{8}$$

$$-r^3x[x-(1-r^{-1})][x^2-(1+r^{-1})x+r^{-1}(1+r^{-1})] = 0. \tag{9}$$

Notice that we have found the first-order FIXED POINTS as well, since two iterations of a first-order FIXED POINT produce a trivial second-order FIXED POINT. The true 2-CYCLES are given by solutions to the quadratic part

$$\begin{aligned} x_\pm^{(2)} &= \tfrac{1}{2}[(1+r^{-1}) \pm \sqrt{(1+r^{-1})^2 - 4r^{-1}(1+r^{-1})}] \\ &= \tfrac{1}{2}[(1+r^{-1}) \pm \sqrt{1+2r^{-1}+r^{-2}-4r^{-1}-4r^{-2}}] \\ &= \tfrac{1}{2}[(1+r^{-1}) \pm \sqrt{1-2r^{-1}-3r^{-2}}] \\ &= \tfrac{1}{2}[(1+r^{-1}) \pm r^{-1}\sqrt{(r-3)(r+1)}]. \end{aligned} \tag{10}$$

These solutions are only REAL for $r \geq 3$, so this is where the 2-CYCLE begins. Note that the 2-cycle can also be found by computing the DISCRIMINANT of

$$\frac{f^2(x) - x}{f(x) - x} = r^2x^2 - r(1+r)x + (1+r) = 0, \tag{11}$$

which is

$$\frac{(1+r)(3-r)}{r^2}. \tag{12}$$

When this equals 0, two roots coincide, so $r_2 = 3$ is the onset of period doubling.

Now look for the onset of the 3-CYCLE. To eliminate the 1-CYCLES, consider

$$\frac{f^3(x) - x}{f(x) - x} = 0. \tag{13}$$

This gives

$$\begin{aligned} &1+r+r^2-(r^4+2r^3+2r^2+r)x \\ &+(2r^5+3r^4+3r^3+r^2)x^2 \\ &-(r^6+5r^5+3r^4+r^3)x^3+(3r^6+4r^5+r^4)x^4 \\ &-(3r^6-r^5)x^5+r^6x^5 = 0. \end{aligned} \tag{14}$$

The ROOTS of this equation are all IMAGINARY for r less than some cutoff r_3, at which point two of them convert to REAL roots. The value of r_3 can be found by computing the DISCRIMINANT of (14),

$$D = \frac{(r^2-5r+7)^2(r^2-2r-7)^3(1+r+r^2)^2}{r^{30}}. \tag{15}$$

When the DISCRIMINANT is zero, two roots coincide. This happens at $r_3 = 1 + 2\sqrt{2}$, so the 3-CYCLE starts at r_3.

To find the onset of the 4-CYCLE, eliminate the 2- and 1-CYCLES by considering

$$\frac{f^4(x) - x}{f^2(x) - x} = 0. \tag{16}$$

This gives

$$1+r^2+(-r^2-r^3-r^4-r^5)x$$

$$+(2r^3+r^4+4r^5+r^6+2r^7)x^2$$
$$+(-r^3-5r^5-4r^6-5r^7-4r^8-r^9)x^3$$
$$+(2r^5+6r^6+4r^7+14r^8+5r^9+3r^{10})x^4$$
$$+(-4r^6-r^7-18r^8-12r^9-12r^{10}-3r^{11})x^5$$
$$+(r^6+10r^8+17r^9+18r^{10}+15r^{11}+r^{12})x^6$$
$$+(-2r^8-14r^9-12r^{10}-30r^{11}-6r^{12})x^7$$
$$+(6r^9+3r^{10}+30r^{11}+15r^{12})x^8$$
$$+(-r^9-15r^{11}-20r^{12})x^9+(3r^{11}+15r^{12})x^{10} \quad (17)$$

The value of r_4 can be found by computing the DISCRIMINANT of (17),

$$D=\frac{(r^2+1)^3(r^2-4r+5)^3}{r^{132}}$$
$$\times(r^6-6r^5+3r^4+28r^3-9r^2-54r-135), \quad (18)$$

which has roots at $r_4=1+\sqrt{6}$, as well as at the 2nd root of

$$r^6-6r^5+3r^4+28r^3-9r^2-54r-135=0.$$

The 4-CYCLE therefore starts at $r_4=1+\sqrt{6}=3.449489\ldots$.

The onset of 5-cycles can be found analogously, and gives a messy 22nd-order polynomial in r whose real positive roots are 3.73817, 3.90557, and 3.99026.

In general, the set of $n+1$ equations which can be solved to give the onset of an arbitrary n-cycle (Saha and Strogatz 1995) is

$$\begin{cases} x_2=rx_1(1-x_1) \\ x_3=rx_2(1-x_2) \\ \vdots \\ x_n=rx_{n-1}(1-x_{n-1}) \\ x_1=rx_n(1-x_n) \\ r^n\ \prod_{k=1}^n(1-2x_k)=1. \end{cases} \quad (19)$$

The first n of these give $f(x)$, $f^2(x)$, ..., $f^n(x)$, and the last uses the fact that the onset of period n occurs by a TANGENT BIFURCATION, so the nth DERIVATIVE is 1. For small n, these can be solved exactly, but the complexity rapidly increases with n

For $n=2$, the solutions (x_1, x_2, r) are given by (0, 0, $\pm$ 1) and (2/3, 2/3, 3), so the first BIFURCATION occurs at $r_2=3$.

For $n=3$,

$$\frac{d[f^3(x)]}{dx}=\frac{d[f^3(x)]}{d[f^2(x)]}\frac{d[f^2(x)]}{d[f(x)]}\frac{d[f(x)]}{dx}$$
$$=\frac{d[f(z)]}{dz}\frac{d[f(y)]}{dy}\frac{d[f(x)]}{dx}$$
$$=r^3(1-2z)(1-2y)(1-2x). \quad (20)$$

Solving the resulting CUBIC EQUATION using computer algebra gives

$$r=1+2\sqrt{2} \quad (21)$$

and x_1, x_2, x_3 the 2nd, 4th, and 5th roots of the sextic

$$343x^6-980x^5+868x^4-134x^3-161x^2+70x-7 = 0, \quad (22)$$

giving numerical roots

$$x_1\approx 0.514355 \quad (23)$$
$$x_2\approx 0.956318 \quad (24)$$
$$x_3\approx 0.159929 \quad (25)$$
$$r\approx 3.828427. \quad (26)$$

Saha and Strogatz (1995) give a simplified algebraic treatment for the 3-cycle which involves solving

$$r^3(1-2\alpha+4\beta-8\gamma)=1, \quad (27)$$

together with three other simultaneous equations, where

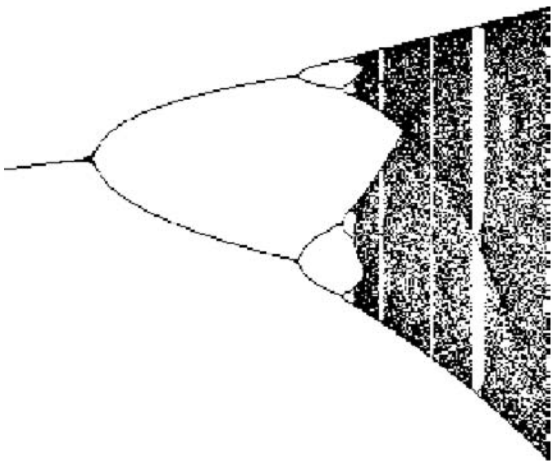
$$\alpha\equiv x_1+x_2+x_3 \quad (28)$$
$$\beta\equiv x_1x_2+x_1x_3+x_2x_3 \quad (29)$$
$$\gamma\equiv x_1x_2x_3. \quad (30)$$

Further simplifications still are provided in Bechhoeffer (1996) and Gordon (1996), but neither of these techniques generalizes easily to higher CYCLES. Bechhoeffer (1996) expresses the three additional equations as

$$2\alpha=3+r^{-1} \quad (31)$$
$$4\beta=\tfrac{3}{2}+5r^{-1}+\tfrac{3}{2}r^{-2} \quad (32)$$
$$8\gamma=-\tfrac{1}{2}+\tfrac{7}{2}r^{-1}+\tfrac{5}{2}r^{-2}+\tfrac{5}{2}r^{-3}, \quad (33)$$

giving

$$r^2-2r-7=0. \quad (34)$$



This has the positive solution found previously, $r_3=1+2\sqrt{2}$.

Gordon (1996) derives not only the value for the onset of the 3-CYCLE, but also an upper bound for the r-values supporting stable period-3 orbits. This value is obtained by solving the CUBIC EQUATION

$$s^3-11s^2+37s-108=0 \quad (35)$$

for s, then

$$r'=1+\sqrt{s} \quad (36)$$
$$=1+\sqrt{\tfrac{11}{3}+\left(\tfrac{1915}{54}+\tfrac{5}{2}\sqrt{201}\right)^{1/3}+\left(\tfrac{1915}{54}-\tfrac{5}{2}\sqrt{201}\right)^{1/3}}$$
$$=3.841499007543\ldots \quad (37)$$

The illustration above shows the logistic map. A table of the CYCLE type and value of r_n at which the cycle 2^n appears is given below.

n	cycle (2^n)	r_n
1	2	3
2	4	3.449490
3	8	3.544090
4	16	3.564407
5	32	3.568750
6	64	3.56969
7	128	3.56989
8	256	3.569934
9	512	3.569943
10	1024	3.5699451
11	2048	3.569945557
∞	ACC. PT.	3.569945672

For additional values, see Rasband (1990, p. 23). Note that the table in Tabor (1989, p. 222) is incorrect, as is the $n=2$ entry in Lauwerier (1991). The period doubling BIFURCATIONS come faster and faster (8, 16, 32, ...), then suddenly break off. Beyond a certain point known as the ACCUMULATION POINT, periodicity gives way to CHAOS, as illustrated below. In the middle of the complexity, a window suddenly appears with a regular period like 3 or 7 as a result of MODE LOCKING. The period-3 BIFURCATION occurs at $r=1+2\sqrt{2}=3.828427$, and PERIOD DOUBLINGS then begin again with CYCLES of 6, 12, ...and 7, 14, 28, ..., and then once again break off to CHAOS.

It is relatively easy to show that the logistic map is chaotic on an invariant Cantor set for $r>2+\sqrt{5}\approx 4.236$ (Devaney 1989, pp. 31–0; Gulik 1992, pp. 112–26; Holmgren 1996, pp. 69–5), but in fact, it is also chaotic for all $r>4$ (Robinson 1995, pp. 33–7; Kraft 1999).

The logistic equation has CORRELATION EXPONENT 0.500 ± 0.005 (Grassberger and Procaccia 1983), CAPACITY DIMENSION 0.538 (Grassberger 1981), and INFORMATION DIMENSION 0.5170976 (Grassberger and Procaccia 1983).

Logistic Equation r = 4

With $r=4$, the LOGISTIC EQUATION becomes

$$x_{n+1} = 4x_n(1-x_n), \tag{1}$$

which is equivalent to the TENT MAP with $\mu = 1$. Now let

$$x \equiv \sin^2(\tfrac{1}{2}\pi y) = \tfrac{1}{2}[1-\cos(\pi y)] \tag{2}$$

$$\sqrt{x} = \sin\left(\tfrac{1}{2}\pi y\right) \tag{3}$$

$$y = \frac{2}{\pi}\sin^{-1}(\sqrt{x}), \tag{4}$$

so

$$\frac{dy}{dx} = \frac{2}{\pi}\frac{1}{\sqrt{1-x}}\,\tfrac{1}{2}x^{-1/2} = \frac{1}{\pi\sqrt{x(1-x)}}. \tag{5}$$

Manipulating (2) gives

$$\begin{aligned}\sin^2\left(\tfrac{1}{2}\pi y_{n+1}\right) &= 4\,\tfrac{1}{2}[1-\cos(\pi y_n)]\left\{1-\tfrac{1}{2}\left[1-\tfrac{1}{2}(1-\cos(\pi y_n)\right]\right\}\\ &= 2[1-\cos(\pi y = 1-\cos^2(\pi y_n)\sin^2(\pi y_n),\end{aligned} \tag{6}$$

so

$$\tfrac{1}{2}\pi y_{n+1} = \pm y_n + s\pi \tag{7}$$

$$y_{n+1} = \pm 2y_n + \tfrac{1}{2}s. \tag{8}$$

But $y \in [0,\ 1]$. Taking $y_n \in [0,\ 1/2]$, then $s=0$ and

$$y_{n+1} = 2y_n. \tag{9}$$

For $y \in [1/2,\ 1]$, $s=1$ and

$$y_{n+1} = 2-2y_n. \tag{10}$$

Combining gives

$$y_{n+1} = \begin{cases} 2y_n & \text{for } y_n \in \left[0,\ \tfrac{1}{2}\right] \\ 2-2y_n & \text{for } y_n \in \left[\tfrac{1}{2},\ 1\right],\end{cases} \tag{11}$$

which can be written

$$y_{n+1} = 1 - 2\left|x_n - \tfrac{1}{2}\right|, \tag{12}$$

which is just the TENT MAP with $\mu = 1$, whose NATURAL INVARIANT in y is

$$\rho(y) = 1. \tag{13}$$

Transforming back to x therefore gives

$$\begin{aligned}\rho(x) &= \left|\frac{dy}{dx}\right|\rho(y(x)) = \frac{2}{\pi}\frac{1}{\sqrt{1-x}}\,\tfrac{1}{2}x^{-1/2}\\ &= \frac{1}{\pi\sqrt{x(1-x)}}.\end{aligned} \tag{14}$$

This can also be derived from

$$\rho(x) = \lim_{N\to\infty}\frac{1}{N}\sum_{i=1}^{N}\delta(x_i - x) = \frac{1}{\pi\sqrt{x(1-x)}}, \tag{15}$$

where $\delta(x)$ is the DELTA FUNCTION.

Logistic Growth Curve

The POPULATION GROWTH law which arises frequently in biology and is given by the differential equation

$$\frac{dN}{dt} = \frac{r(K-N)}{K}, \tag{1}$$

where r is the MALTHUSIAN PARAMETER and K is the so-called CARRYING CAPACITY (i.e., the maximum sustainable population). Rearranging and integrating both sides gives

$$\int_{N_0}^{N}\frac{dN}{K-N} = \frac{r}{K}\int_0^t dt \tag{2}$$

$$\ln\left(\frac{N_0-K}{N-K}\right) = \frac{r}{K}\,t \tag{3}$$

$$N(t) = K + (N_0 - K)e^{-rt/K}. \tag{4}$$

The curve

$$y = \frac{a}{1+bq^x} \tag{5}$$

is sometimes also known as the logical curve.

Logistic Map

LOGISTIC EQUATION

Logit Transformation

The function

$$z = f(x) = \ln\left(\frac{x}{1-x}\right).$$

This function has an inflection point at $x = 1/2$, where

$$f''(x) = \frac{2x-1}{x^2(x-1)^2} = 0.$$

Applying the logit transformation to values obtained by iterating the LOGISTIC EQUATION generates a sequence of RANDOM NUMBERS having distribution

$$P_z = \frac{1}{\pi(e^{x/2} + e^{-x/2})},$$

which is very close to a GAUSSIAN DISTRIBUTION.

Logos

A generalization of a HEYTING ALGEBRA which replaces BOOLEAN ALGEBRA in "intuitionistic" LOGIC.

See also TOPOS

Log-Series Distribution

The terms in the series expansion of $\ln(1-\theta)$ about $\theta = 0$ are proportional to this distribution.

$$P(n) = -\frac{\theta^n}{n\ln(1-\theta)} \tag{1}$$

$$D(n) \equiv \sum_{i=1}^{n} P(i) = \frac{\theta^{1+n}\Phi(\theta, 1, 1+n) + \ln(1-\theta)}{\ln(1-\theta)}, \tag{2}$$

where Φ is the LERCH TRANSCENDENT. The MEAN, VARIANCE, SKEWNESS, and KURTOSIS

$$\mu = \frac{\theta}{(\theta-1)\ln(1-\theta)} \tag{3}$$

$$\sigma^2 = -\frac{\theta[\theta + \ln(1-\theta)]}{(\theta-1)^2[\ln(1-\theta)]^2} \tag{4}$$

$$\gamma_1 = \frac{2\theta^2 + 3\theta\ln(1-\theta) + (1+\theta)\ln^2(1-\theta)}{\ln(1-\theta)[\theta+\ln(1-\theta)]\sqrt{-\theta[\theta+\ln(1-\theta)]}} \times \ln(1-\theta) \tag{5}$$

$$\gamma_2 = \frac{6\theta^3 + 12\theta^2\ln(1-\theta) + \theta(7+4\theta)\ln^2(1-\theta)}{\theta[\theta+\ln(1-\theta)]^2} + \frac{(1+4\theta+\theta^2)\ln^3(1-\theta)}{\theta[\theta+\ln(1-\theta)]^2}. \tag{6}$$

Log-Weibull Distribution

FISHER-TIPPETT DISTRIBUTION

Lommel Differential Equation

A generalization of the BESSEL DIFFERENTIAL EQUATION

$$z^2\frac{d^2y}{dz^2} + z\frac{dy}{dz} - (z^2+\nu^2)y = kz^{\mu+1}$$

(Watson 1966, p. 345; Zwillinger 1997, p. 125; Gradshteyn and Ryzhik 2000, p. 986). A further generalization gives

$$z^2\frac{d^2y}{dz^2} + z\frac{dy}{dz} - (z^2+\nu^2)y = \pm kz^{\mu+1}.$$

The solutions are LOMMEL FUNCTIONS.

See also LOMMEL FUNCTION

Lommel Function

There are several functions called "Lommel functions." One type of Lommel function is the solution to the LOMMEL DIFFERENTIAL EQUATION with a PLUS SIGN, given by

$$y = ks_{\mu,\nu}(z), \tag{1}$$

where

$$s_{\mu,\nu}^{(+)}(z) \equiv \tfrac{1}{2\pi}\left[Y_\nu(z)\int_0^z z^\mu J_\nu(z)\,dz - J_\nu(z)\int_0^z z^\mu Y_\nu(z)\,dz\right]. \tag{2}$$

Here, $J_\nu(z)$ and $Y_\nu(z)$ are BESSEL FUNCTIONS OF THE FIRST and SECOND KINDS (Watson 1966, p. 346). If a minus sign precedes k, then the solution is

$$s_{\mu,\nu}^{-} \equiv I_\nu(z)\int_z^{c_1} z^\mu K_\nu(z)\,dz - J_\nu(z)\int_{c_2}^z z^\mu I_\nu(z)\,dz, \tag{3}$$

where $K_\nu(z)$ and $I_\nu(z)$ are MODIFIED BESSEL FUNCTIONS OF THE FIRST and SECOND KINDS.

Lommel functions of two variables are related to the BESSEL FUNCTION OF THE FIRST KIND and arise in the theory of diffraction and, in particular, Mie scattering (Watson 1966, p. 537),

$$U_n(w,z) = \sum_{m=0}^\infty (-1)^m \left(\frac{w}{z}\right)^{n+2m} J_{n+2m}(z) \tag{4}$$

$$V_n(w,z) = \sum_{m=0}^\infty (-1)^m \left(\frac{w}{z}\right)^{-n-2m} J_{-n-2m}(z). \tag{5}$$

Longest Increasing Scattered Subsequence

The longest increasing scattered subsequence is the longest subsequence of increasing terms, where intervening nonincreasing terms may be dropped. Finding the largest scattered subsequence is a much harder problem. The longest increasing scattered subsequence of a PARTITION can be found using `LongestIncreasingSubsequence[p]` in the *Mathematica* add-on package `DiscreteMath'Com-`

binatorica` (which can be loaded with the command << DiscreteMath`). For example, the longest increasing scattered subsequence of the PERMUTATION {6, 3, 4, 8, 10, 5, 7, 1, 9, 2} is {3, 4, 5, 7, 9}, whereas the longest contiguous subsequence is {3, 4, 8, 10}.

Any sequence of n^2+1 distinct integers must contain either an increasing or decreasing scattered subsequence of length $n+1$ (Erdos and Szekeres 1935; Skiena 1990, p. 75).

See also LONGEST INCREASING SUBSEQUENCE, PERMUTATION

Longest Increasing Subsequence

The longest increasing subsequence of a given sequence is the subsequence of increasing terms containing the largest number of elements. For example, the longest increasing subsequence of the PERMUTATION {6, 3, 4, 8, 10, 5, 7, 1, 9, 2} is {3, 4, 8, 10}.

Long Exact Sequence

See also LONG EXACT SEQUENCE OF A PAIR AXIOM

Long Exact Sequence of a Pair Axiom

One of the EILENBERG-STEENROD AXIOMS. It states that, for every pair (X, A), there is a natural long exact sequence

$$\ldots \to H_n(A) \to H_n(X) \to H_n(X, A) \to H_{n-1}(A) \to \ldots, \quad (1)$$

where the MAP $H_n(A) \to H_n(X)$ is induced by the INCLUSION MAP $A \to X$ and $H_n(X) \to H_n(X, A)$ is induced by the INCLUSION MAP $(X, \phi) \to (X, A)$. The MAP $H_n(X, A) \to H_{n-1}(A)$ is called the BOUNDARY MAP.

See also EILENBERG-STEENROD AXIOMS

Longimeter

A longimeter is a transparent sheet of plastic with a regular grid of lines inclined at an angle of 30° to the sides of the sheet. By counting the number of squares occupied by a linear feature on a map (such as a river) for six different rotations of the sheet, the length of the feature can be determined.

Longitude

The azimuthal coordinate on the surface of a SPHERE (θ in SPHERICAL COORDINATES) or on a SPHEROID (in PROLATE or OBLATE SPHEROIDAL COORDINATES). Longitude is defined such that $0° = 360°$. Lines of constant longitude are generally called MERIDIANS. The other angular coordinate on the surface of a SPHERE is called the LATITUDE.

The shortest distance between any two points on a SPHERE is the so-called GREAT CIRCLE distance, which can be directly computed from the LATITUDE and longitudes of two points.

See also GREAT CIRCLE, LATITUDE, MERIDIAN, OBLATE SPHEROIDAL COORDINATES, PROLATE SPHEROIDAL COORDINATES

Longitudinal Data

Data resulting from the observation of a population on a number of variables over time. Whenever observations are made more than once, the data is considered to be longitudinal.

Long Prime

FULL REPTEND PRIME

Look and Say Sequence

The INTEGER SEQUENCE beginning with a single digit in which the next term is obtained by describing the previous term. Starting with 1, the sequence would be defined by "1, one 1, two 1s, one 2 one 1," etc., and the result is 1, 11, 21, 1211, 111221, 312211, 13112221, 1113213211, ... (Sloane's A005150).

Starting the sequence instead with the digit d for $2 \le d \le 9$ gives d, $1d$, $111d$, $311d$, $13211d$, $111312211d$, $31131122211d$, $1321132132211d$, ... The sequences for $d = 2$ and 3 are Sloane's A006751 and A006715. n

terms of the look and say sequence (given as lists of digits) starting with digit d can be implemented in *Mathematica* as follows.

```
RunLengthEncode[x_List]  :=  (Through[{First,
Length}[#]]       &)       /@       Split[x]
LookAndSay[n_Integer?Positive,    d_:1]    :=
NestList[Flatten[Reverse                   /@
RunLengthEncode[#]] &, {d}, n - 1]
```

The number of DIGITS in the nth term the sequence for $1 \le d \le 9$ is given by the sequence 1, 2, 2, 4, 6, 6, 8, 10, 14, 20, 26, 34, 46, 62, ... (Sloane's A005341), which is asymptotic to $C\lambda^n$, where C is a constant and

$$\lambda = 1.303577269034296\ldots$$

(Sloane's A014715) is CONWAY'S CONSTANT, given by the unique positive real root of the POLYNOMIAL

$$\begin{aligned} 0 = {} & x^{71} - x^{69} - 2x^{68} - x^{67} + 2x^{66} + 2x^{65} + x^{64} - x^{63} - x^{62} \\ & - x^{61} - x^{60} - x^{59} + 2x^{58} + 5x^{57} + 3x^{56} - 2x^{55} - 10x^{54} \\ & - 3x^{53} - 2x^{52} + 6x^{51} + 6x^{50} + x^{49} + 9x^{48} - 3x^{47} \\ & - 7x^{46} - 8x^{45} - 8x^{44} + 10x^{43} + 6x^{42} + 8x^{41} - 4x^{40} \\ & - 12x^{39} + 7x^{38} - 7x^{37} + 7x^{36} + x^{35} - 3x^{34} + 10x^{33} \\ & + x^{32} - 6x^{31} - 2x^{30} - 10x^{29} - 3x^{28} + 2x^{27} + 9x^{26} \\ & - 3x^{25} + 14x^{24} - 8x^{23} - 7x^{21} + 9x^{20} - 3x^{19} - 4x^{18} \\ & - 10x^{17} - 7x^{16} + 12x^{15} + 7x^{14} + 2x^{13} - 12x^{12} - 4x^{11} \\ & - 2x^{10} - 5x^{9} + x^{7} - 7x^{6} + 7x^{5} - 4x^{4} + 12x^{3} - 6x^{2} \\ & + 3x - 6. \end{aligned}$$

In fact, the constant is even more general than this, applying to *all* starting sequences (i.e., even those starting with arbitrary starting digits), with the exception of 22, a result which follows from the COSMOLOGICAL THEOREM. Conway discovered that strings sometimes factor as a concatenation of two strings whose descendants never interfere with one another. A string with no nontrivial splittings is called an "element," and other strings are called "compounds." Every string of 1s, 2s, and 3s eventually "decays" into a compound of 92 special elements, named after the chemical elements.

Lorentz Group

The Lorentz group is the GROUP L of time-preserving linear ISOMETRIES of MINKOWSKI SPACE $\mathbb{R}^4$ with the pseudo-Riemannian metric

$$dr^2 = -dt^2 + dx^2 + dy^2 + dz^2.$$

It is also the GROUP of ISOMETRIES of 3-D HYPERBOLIC SPACE. It is time-preserving in the sense that the unit time VECTOR (1, 0, 0, 0) is sent to another VECTOR (t, x, y, z) such that $t > 0$.

A consequence of the definition of the Lorentz group is that the full GROUP of time-preserving isometries of MINKOWSKI $\mathbb{R}^4$ is the GROUP DIRECT PRODUCT of the group of translations of $\mathbb{R}^4$ (i.e., $\mathbb{R}^4$ itself, with addition as the group operation), with the Lorentz group, and that the full isometry group of the MINKOWSKI $\mathbb{R}^4$ is a group extension of $\mathbb{Z}_2$ by the product $L \otimes \mathbb{R}^4$.

The Lorentz group is invariant under space rotations and LORENTZ TRANSFORMATIONS.

Lorentz Tensor

The TENSOR in the LORENTZ TRANSFORMATION given by

$$\mathsf{L} \equiv \begin{bmatrix} \gamma & -\gamma\beta & 0 & 0 \\ -\gamma\beta & \gamma & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}, \quad (1)$$

where beta and gamma are defined by

$$\beta \equiv \frac{v}{c} \quad (2)$$

$$\gamma \equiv \frac{1}{\sqrt{1-\beta^2}}. \quad (3)$$

See also LORENTZ GROUP, LORENTZ TRANSFORMATION

Lorentz Transformation

A 4-D transformation satisfied by all FOUR-VECTORS a^ν,

$$a'^\mu = \Lambda^\mu_\nu a^\nu. \quad (1)$$

In the theory of special relativity, the Lorentz transformation replaces the GALILEAN TRANSFORMATION as the valid transformation law between reference frames moving with respect to one another at constant VELOCITY. Let x^ν be the POSITION FOUR-VECTOR with $x^0 = ct$, and let the relative motion be along the x^1 axis with VELOCITY v. Then (1) becomes

$$x'^\mu = \Lambda^\mu_\nu x^\nu, \quad (2)$$

where the LORENTZ TENSOR is given by

$$\mathsf{L} = \begin{bmatrix} \Lambda^0_0 & \Lambda^0_1 & \Lambda^0_2 & \Lambda^0_3 \\ \Lambda^1_0 & \Lambda^1_1 & \Lambda^1_2 & \Lambda^1_3 \\ \Lambda^2_0 & \Lambda^2_1 & \Lambda^2_2 & \Lambda^2_3 \\ \Lambda^3_0 & \Lambda^3_1 & \Lambda^3_2 & \Lambda^3_3 \end{bmatrix} \equiv \begin{bmatrix} \gamma & -\gamma\beta & 0 & 0 \\ -\gamma\beta & \gamma & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}. \quad (3)$$

Here,

$$\beta \equiv \frac{v}{c} \quad (4)$$

$$\gamma \equiv \frac{1}{\sqrt{1-\beta^2}}. \quad (5)$$

Written explicitly, the transformation between x^ν and $x^{\nu'}$ coordinate is

$$x^{0'} = \gamma(x^0 - \beta x^1) \quad (6)$$

$$x^{1'} = \gamma(x^1 - \beta x^0) \quad (7)$$

$$x^{2'} = x^2 \quad (8)$$

$$x^{3'} = x^3. \quad (9)$$

The DETERMINANT of the upper left 2×2 MATRIX in (3) is

$$D = (\gamma)^2 - (-\gamma\beta)^2 = \gamma^2(1-\beta^2) = \frac{\gamma^2}{\gamma^2} = 1, \quad (10)$$

so

$$\mathsf{L}^{-1} = \begin{bmatrix} (\Lambda^{-1})^0_0 & (\Lambda^{-1})^0_1 & (\Lambda^{-1})^0_2 & (\Lambda^{-1})^0_3 \\ (\Lambda^{-1})^1_0 & (\Lambda^{-1})^1_1 & (\Lambda^{-1})^1_2 & (\Lambda^{-1})^1_3 \\ (\Lambda^{-1})^2_0 & (\Lambda^{-1})^2_1 & (\Lambda^{-1})^2_2 & (\Lambda^{-1})^2_3 \\ (\Lambda^{-1})^3_0 & (\Lambda^{-1})^3_1 & (\Lambda^{-1})^3_2 & (\Lambda^{-1})^3_3 \end{bmatrix}$$

$$\equiv \begin{bmatrix} \gamma & \gamma\beta & 0 & 0 \\ \gamma\beta & \gamma & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}. \tag{11}$$

A Lorentz transformation along the x^1-axis can also be written

$$\begin{bmatrix} x^{0'} \\ x^{1'} \\ x^{2'} \\ x^{3'} \end{bmatrix} \begin{bmatrix} \cosh\theta & -\sinh\theta & 0 & 0 \\ -\sinh\theta & \cosh\theta & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x^0 \\ x^1 \\ x^2 \\ x^3 \end{bmatrix}. \tag{12}$$

where θ is called the rapidity,

$$x^0 \equiv ct, \tag{13}$$

and

$$\tanh\theta \equiv \beta \equiv \frac{v}{c} \tag{14}$$

$$\cosh\theta \equiv \gamma \equiv \frac{1}{\sqrt{1-\beta^2}} \tag{15}$$

$$\sinh\theta = \gamma\beta. \tag{16}$$

Lorentzian Distribution

Cauchy Distribution

Lorentzian Function

The Lorentzian function is the singly peaked function given by

$$L(x) = \frac{1}{\pi} \frac{\frac{1}{2}\Gamma}{(x-x_0)^2 + \left(\frac{1}{2}\Gamma\right)^2}. \tag{1}$$

It is normalized to that

$$\int_{-\infty}^{\infty} L(x) = 1. \tag{2}$$

It has a maximum at $x = x_0$, where

$$L'(x) = -\frac{16(x-x_0)\Gamma}{\pi[4(x-x_0)^2+\Gamma^2]} = 0. \tag{3}$$

Its value at the maximum is

$$L(x_0) = \frac{2}{\pi\,\Gamma}. \tag{4}$$

It is equal to half its maximum at

$$x = \left(x_0 \pm \tfrac{1}{2}\Gamma\right), \tag{5}$$

and so has full width at half maximum Γ. The function has inflection points at

$$L''(x) = 16\,\Gamma\,\frac{12(x-x_0)^2 - \Gamma^2}{\pi[4(x-x_0)^2+\Gamma^2]} = 0, \tag{6}$$

giving

$$x_1 = x_0 - \tfrac{1}{6}\sqrt{3}\,\Gamma, \tag{7}$$

where

$$L(x_1) = \frac{3}{2\pi\,\Gamma}. \tag{8}$$

The Lorentzian function gives the shape of certain types of spectral lines and is the distribution function in the Cauchy distribution. The Lorentzian function has Fourier transform

$$\mathcal{F}\left[\frac{1}{\pi}\frac{\frac{1}{2}\Gamma}{(x-x_0)^2+(\frac{1}{2}\Gamma)^2}\right] = e^{-2\pi i k x_0 - \Gamma\pi|k|}. \tag{9}$$

See also Cauchy Distribution, Damped Exponential Cosine Integral, Fourier Transform–Lorentzian Function

Lorentzian Inner Product

The standard Lorentzian inner product on $\mathbb{R}^4$ is given by

$$-dx_0^2 + dx_1^2 + dx_2^2 + dx_3^2, \tag{1}$$

i.e, for vectors $\mathbf{v}$ and $\mathbf{w}$,

$$\langle \mathbf{v},\ \mathbf{w}\rangle = -v_0w_0 + v_1w_1 + v_2w_2 + v_3w_3. \tag{2}$$

The Lorentzian inner product is used in special relativity as a measurement, replacing distances, which is independent of reference frame. The variables x_1, x_2, and x_3 can be thought of as space variables, and the x_0 variable as the time variable. Sometimes, the time variable is labelled t instead of x_0 and when used in special relativity, $x_0 = ct$, where c is the speed of light. The formula (1) uses the convention that units are chosen so that the speed of light has the value $c = 1$ in order to simplify formulas.

For a vector $\mathbf{v}$, the sign of $\langle \mathbf{v}, \mathbf{v} \rangle$ determines the type of $\mathbf{v}$. If it is positive, then $\mathbf{v}$ is a space-like vector. If it is zero, then $\mathbf{v}$ is called a null vector, or light-like vector. If it is negative, then $\mathbf{v}$ is called a time-like vector. After a change of variables, it is possible to rewrite the Lorentzian inner product as above where t is in the direction of a given time-like vector v with $\langle \mathbf{v}, \mathbf{v} \rangle = -1$. Such a change of variables corresponds to a change in reference frame. Altogether, these form the LORENTZ GROUP, also called the ORTHOGONAL GROUP $O(3, 1)$.

See also ORTHOGONAL GROUP

Lorenz Asymmetry Coefficient

This entry contributed by CHRISTIAN DAMGAARD

The Lorenz asymmetry coefficient is a summary statistic of the Lorenz curve that measures the degree of asymmetry of a LORENZ CURVE. The Lorenz asymmetry coefficient is defined as

$$S \equiv F(\mu) + L(\mu), \tag{1}$$

where the functions F and L are defined as for the Lorenz curve. If $S > 1$, then the point where the LORENZ CURVE is parallel with the line of equality is above the axis of symmetry. Correspondingly, if $S < 1$, then the point where the LORENZ CURVE is parallel to the line of equality is below the axis of symmetry.

The sample statistic S can be calculated from ordered size data using the following equations

$$\delta = \frac{\mu - x'_m}{x'_{m+1} - x'_m} \tag{2}$$

$$F(\mu) = \frac{m + \delta}{n} \tag{3}$$

$$L(\mu) = \frac{L_m + \delta x'_{m+1}}{L_n}, \tag{4}$$

where m is the number of individuals with a size less than μ.

Lorenz Attractor

The Lorenz attractor is a STRANGE ATTRACTOR that arises in a simplified system of equations describing the 2-D flow of fluid of uniform depth H, with an imposed temperature difference ΔT, under gravity g, with buoyancy α, thermal diffusivity κ, and kinematic viscosity ν. The full equations are

$$\frac{\partial}{\partial t}(\nabla^2 \phi) = \frac{\partial \psi}{\partial z}\frac{\partial}{\partial x}(\nabla^2 \psi) - \frac{\partial \psi}{\partial x}\frac{\partial}{\partial z}(\nabla^2 \psi) + \nu \nabla^2(\nabla^2 \psi) + g\alpha \frac{dT}{dx} \tag{1}$$

$$\frac{\partial T}{\partial t} = \frac{\partial T}{\partial z}\frac{\partial \psi}{\partial x} - \frac{\partial \theta}{\partial x}\frac{\partial \psi}{\partial z} + \kappa \nabla^2 T + \frac{\Delta T}{H}\frac{\partial \psi}{\partial x}. \tag{2}$$

Here, ψ is the "stream function," as usual defined such that

$$u = \frac{\partial \psi}{\partial x}, \quad v = \frac{\partial \psi}{\partial x}. \tag{3}$$

In the early 1960s, Lorenz accidentally discovered the chaotic behavior of this system when he found that, for a simplified system, periodic solutions OF THE FORM

$$\psi = \psi_0 \sin\left(\frac{\pi a x}{H}\right)\sin\left(\frac{\pi z}{H}\right) \tag{4}$$

$$\theta = \theta_0 \cos\left(\frac{\pi a x}{H}\right)\sin\left(\frac{\pi z}{H}\right) \tag{5}$$

grew for Rayleigh numbers larger than the critical value, $Ra > Ra_c$. Furthermore, vastly different results were obtained for very small changes in the initial values, representing one of the earliest discoveries of the so-called BUTTERFLY EFFECT.

Lorenz included the following terms in his system of equations,

$$X \equiv \psi_{11} \propto \text{ convective intensity} \tag{6}$$

$$Y \equiv T_{11} \propto \Delta T \text{ between descending and ascending currents} \tag{7}$$

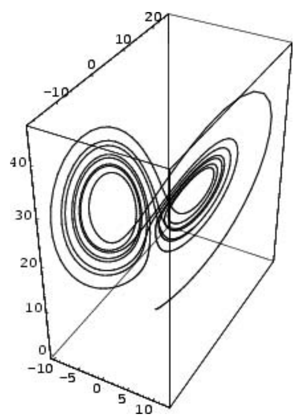
$$Z \equiv T_{02} \propto \Delta \text{ vertical temperature profile from linearity,} \tag{8}$$

and obtained the simplified equations

$$\dot{X} = \sigma(Y - X) \tag{9}$$

$$\dot{Y} = -XZ + rX - Y \quad (10)$$

$$\dot{Z} = XY - bZ, \quad (11)$$



now known as the LORENZ EQUATIONS, where $\dot{X} = dX/dt$, $\dot{Y} = dY/dt$, $\dot{Z} = dZ/dt$, and

$$\sigma \equiv \frac{\nu}{\kappa} = \text{Prandtl number} \quad (12)$$

$$r \equiv \frac{Ra}{Ra_c} = \text{normalized Rayleigh number} \quad (13)$$

$$b \equiv \frac{4}{1 + a^2} = \text{geometric factor}. \quad (14)$$

Lorenz took $b \equiv 8/3$ and $\sigma \equiv 10$.

The CRITICAL POINTS at (0, 0, 0) correspond to no convection, and the CRITICAL POINTS at

$$\left(\sqrt{b(r-1)},\ \sqrt{b(r-1)},\ r-1\right) \quad (15)$$

and

$$\left(-\sqrt{b(r-1)}, -\sqrt{b(r-1)},\ r-1\right) \quad (16)$$

correspond to steady convection. This pair is stable only if

$$r = \frac{\sigma(\sigma + b + 3)}{\sigma - b - 1}, \quad (17)$$

which can hold only for POSITIVE r if $\sigma > b + 1$. The Lorenz attractor has a CORRELATION EXPONENT of 2.05 $\pm$ 0.01 and CAPACITY DIMENSION 2.06 $\pm$ 0.01 (Grassberger and Procaccia 1983). For more details, see Lichtenberg and Lieberman (1983, p. 65) and Tabor (1989, p. 204).

Lorenz Curve

This entry contributed by CHRISTIAN DAMGAARD

The Lorenz curve is used in economics and ecology to describe inequality in wealth or size. The Lorenz curve is a function of the cumulative proportion of ordered individuals mapped onto the corresponding cumulative proportion of their size. Given a sample of n ordered individuals with x'_i the size of individual i and $x'_1 < x'_2 < \ldots < x'_n$, then the sample Lorenz curve is the polygon joining the points $(h/n,\ L_h/L_n)$, where $h = 0, 1, 2, \ldots n$, $L_0 = 0$, and $L_h = \Sigma_{i=1}^{h} x'_i$. Alternatively, the Lorenz curve can be expressed as

$$L(y) = \frac{\int_0^y x\, dF(x)}{\mu},$$

where $F(y)$ is the cumulative distribution function of ordered individuals and μ is the average size.

If all individuals are the same size, the Lorenz curve is a straight diagonal line, called the line of equality. If there is any inequality in size, then the Lorenz curve falls below the line of equality. The total amount of inequality can be summarized by the GINI COEFFICIENT (also called the Gini ratio), which is the ratio between the area enclosed by the line of equality and the Lorenz curve, and the total triangular area under the line of equality. The degree of asymmetry around the axis of symmetry is measured by the so-called LORENZ ASYMMETRY COEFFICIENT.

Los' Theorem

Let I be a set, and let $\mathfrak{U}$ be an ultrafilter on I, let ϕ be a formula of a given language L, and let $\{\mathbb{A}_i : i \in I\}$ be any collection of structures which is indexed by the set I. Denote by $[x]_{\mathfrak{U}}$ the equivalence class of x under $\mathfrak{U}$, for any element x of the product $\prod_{i \in I} \mathbb{A}_i$. Then the ultraproduct $\left(\prod_{i \in I} \mathbb{A}\right)/\mathfrak{U}$ satisfies ϕ via a valuation $s = [(x_i)_{i \in I}]_{\mathfrak{U}}$ in $\left(\prod_{i \in I} \mathbb{A}\right)/\mathfrak{U}$ if and only if Tarski's recursive definition of satisfaction holds,

$$\left\{ i \in I : \mathbb{A}_i \models_{x_i} \phi \right\} \in \mathfrak{U}.$$

Lost in a Forest Problem

The problem of finding the strategy to guarantee reaching the boundary of a given region ("forest") in the shortest distance (i.e., a strategy having the best worst-case performance). For example, one simple strategy would consist of walking in a straight line in a random direction until encountering a boundary. Although this straightforward approach is indeed the best for some simple geometries, other approaches (e.g., walking in a spiral, alternating left and right turns after traveling some fixed distance, etc.) might be optimal for forests with more complicated boundaries.

Lotka-Volterra Equations

An ecological model which assumes that a population x increases at a rate $dx = Ax\,dt$, but is destroyed at a rate $dx = -Bxy\,dt$. Population y decreases at a rate $dy = -Cy\,dt$, but increases at $dy = Dxy\,dt$, giving the coupled differential equations

$$\frac{dx}{dt} = Ax - Bxy \tag{1}$$

$$\frac{dy}{dt} = -Cy + Dxy. \tag{2}$$

Critical points occur when $dx/dt = dy/dt = 0$, so

$$A - By = 0 \tag{3}$$

$$-C + Dx = 0. \tag{4}$$

The sole STATIONARY POINT is therefore located at $(x, y) = (C/D, A/B)$.

Low-Dimensional Topology

Low-dimensional topology usually deals with objects that are 2-, 3-, or 4-dimensional in nature. Properly speaking, low-dimensional topology should be part of DIFFERENTIAL TOPOLOGY, but the general machinery of ALGEBRAIC and DIFFERENTIAL TOPOLOGY gives only limited information. This fact is particularly noticeable in dimensions three and four, and so alternative specialized methods have evolved.

Löwenheim-Skolem Theorem

A fundamental result in MODEL THEORY which states that if a countable theory has a model, then it has a countable model. Furthermore, it has a model of every CARDINALITY greater than or equal to $\aleph_0$ (ALEPH-0). This theorem established the existence of "nonstandard" models of arithmetic.

Lower Bound

A function f is said to have a lower bound c if $c \le f(x)$ for all x in its DOMAIN. The GREATEST LOWER BOUND is called the INFIMUM.

See also INEQUALITY, INFIMUM, SUPREMUM, UPPER BOUND

Lower Central Series (Lie Algebra)

The lower central series of a LIE ALGEBRA $\mathfrak{g}$ is the sequence of subalgebras recursively defined by

$$\mathfrak{g}_{k+1} = [\mathfrak{g}, \mathfrak{g}_k], \tag{1}$$

with $\mathfrak{g}_0 = \mathfrak{g}$. The sequence of subspaces is always decreasing with respect to inclusion or dimension, and becomes stable when $\mathfrak{g}$ is finite dimensional. The notation $[\mathfrak{a}, \mathfrak{b}]$ means the linear span of elements of the form $[A, B]$, where $A \in \mathfrak{a}$ and $B \in \mathfrak{b}$.

When the lower central series ends in the zero subspace, the Lie algebra is called NILPOTENT. For example, consider the LIE ALGEBRA of strictly UPPER TRIANGULAR MATRICES, then

$$\mathfrak{g}_0 = \begin{bmatrix} 0 & a_{12} & a_{13} & a_{14} & a_{15} \\ 0 & 0 & a_{23} & a_{24} & a_{25} \\ 0 & 0 & 0 & a_{34} & a_{35} \\ 0 & 0 & 0 & 0 & a_{45} \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix} \tag{2}$$

$$\mathfrak{g}_1 = \begin{bmatrix} 0 & 0 & a_{13} & a_{14} & a_{15} \\ 0 & 0 & 0 & a_{24} & a_{25} \\ 0 & 0 & 0 & 0 & a_{35} \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix} \tag{3}$$

$$\mathfrak{g}_2 = \begin{bmatrix} 0 & 0 & 0 & a_{14} & a_{15} \\ 0 & 0 & 0 & 0 & a_{25} \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix} \tag{4}$$

$$\mathfrak{g}_3 = \begin{bmatrix} 0 & 0 & 0 & 0 & a_{15} \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix}, \tag{5}$$

and $\mathfrak{g}_4 = 0$. By definition, $\mathfrak{g}^k \subset \mathfrak{g}_k$, where $\mathfrak{g}^k$ is the term in the COMMUTATOR SERIES, as can be seen by the example above.

In contrast to the NILPOTENT LIE ALGEBRAS, the SEMISIMPLE LIE ALGEBRAS have a constant lower central series. Others are in between, e.g.,

$$[\mathfrak{gl}_n, \mathfrak{gl}_n] = \mathfrak{sl}_n, \tag{6}$$

which is semisimple, because the TRACE satisfies

$$\mathrm{Tr}(AB) = \mathrm{Tr}(BA). \tag{7}$$

Here, $\mathfrak{gl}_n$ is a general linear Lie algebra and $\mathfrak{sl}_n$ is the SPECIAL LINEAR LIE ALGEBRA.

Here are some *Mathematica* functions for determining the lower central series, when given a list of matrices which is a basis for $\mathfrak{g}$.

```
MatrixBasis[a_-
List]:=Partition[#1,Length[a[[1]]]]&/@
   LatticeReduce[Flatten/@a]
                  LieCommutator[a_,b_]:=a.b-b.a
NextLCS[gold_List,{}]={};
                     NextLCS[gold_List,g_List]:=
MatrixBasis[Flatten[Outer[LieCommutator,gold,-
```

```
g,1],1]]                              kthLCS[g_List,
k_Integer]:=Nest[NextLCS[g,#1]&,g,k]
```

For example,

```
gl5=Flatten[Table[ReplacePart[
                                                Ta-
ble[0,{i,5},{j,5}],1,{k,1}],{k,5},{l,5}],1];
  sl5=kthLCS[gl5, 1]
```

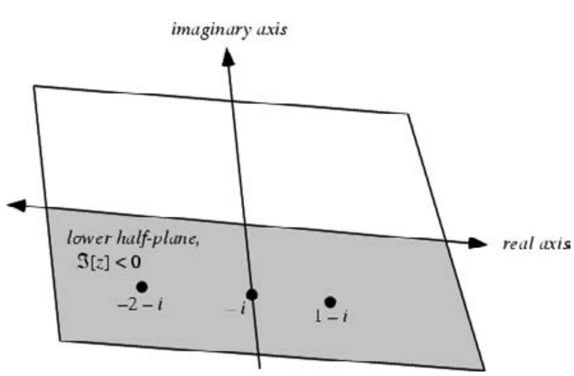
Lower Denjoy Sum

Lower Sum

Lower Factorial

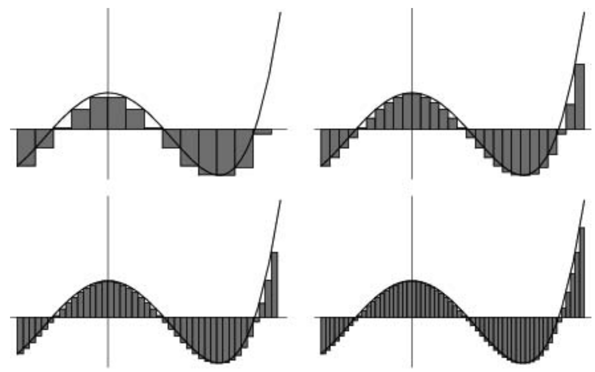
Falling Factorial



Lower Half-Disk

The unit lower half-disk is the portion of the complex plane satisfying $\{|z| \leq 1, \Im[z] < 0\}$.

See also Disk, Real Axis, Semicircle, Unit Disk, Lower Half-Plane, Upper Half-Disk



Lower Half-Plane

The portion of the complex plane $\{x+iy : x, y \in (-\infty, \infty)\}$ satisfying $y = \Im[z] < 0$, i.e., $\{x+iy : x \in (-\infty, \infty), y \in (\infty, 0)\}$.

See also Complex Plane, Half-Plane, Left Half-Plane, Lower Half-Disk, Right Half-Plane, Upper Half-Plane

Lower Integral

The limit of a lower sum, when it exists, as the mesh size approaches 0.

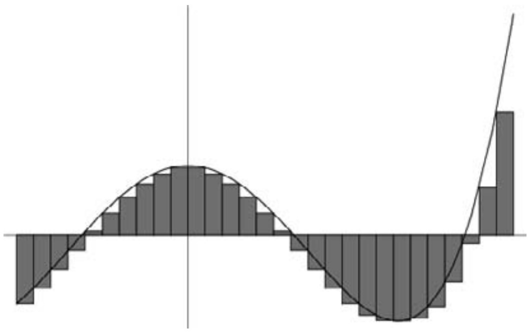
See also Lower Sum, Riemann Integral, Upper Integral

Lower Limit

Let the least term h of a sequence be a term which is smaller than all but a finite number of the terms which are equal to h. Then h is called the lower limit of the sequence.

A lower limit of a series

$$\text{lower} \lim_{n\to\infty} S_n = \underline{\lim}_{n\to\infty} S_n = h$$



is said to exist if, for every $\epsilon > 0$, $|S_n - h| < \epsilon$ for infinitely many values of n and if no number less than h has this property.

See also Infimum Limit, Limit, Supremum Limit, Upper Limit

References

Bromwich, T. J. I'a and MacRobert, T. M. "Upper and Lower Limits of a Sequence." §5.1 in *An Introduction to the Theory of Infinite Series, 3rd ed.* New York: Chelsea, p. 40 1991.

Lower Sum

For a given function $f(x)$ over a partition of a given interval, the lower sum is the sum of box areas $f(x_k^*)\Delta x_k$ using the smallest value of the function $f(x_k^*)$) in each subinterval Δx_k.

See also Lower Integral, Riemann Integral, Upper Sum

Lower Triangular Matrix

A triangular matrix **L** of the form

$$L_{ij} = \begin{cases} a_{ij} & \text{for } i \geq j \\ 0 & \text{for } i < j. \end{cases}$$

Written explicitly,

$$\mathbf{L} = \begin{bmatrix} a_{11} & 0 & \cdots & 0 \\ a_{21} & a_{22} & \cdots & 0 \\ \vdots & \vdots & \ddots & 0 \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{bmatrix}$$

A lower triangular matrix with elements `f[i,j]` below the diagonal can be formed using `LowerDiagonalMatrix[`f, n`]` in the *Mathematica* add-on package `LinearAlgebra`MatrixMultiplication`` (which can be loaded with the command `<<LinearAlgebra``).

See also Triangular Matrix, Upper Triangular Matrix

References

Ayres, F. Jr. *Theory and Problems of Matrices.* New York: Schaum, p. 10, 1962.

Lower-Trimmed Subsequence

The lower-trimmed subsequence of $x = \{x_n\}$ is the sequence $V(x)$ obtained by subtracting 1 from each x_n and then removing all 0s. If x is a fractal sequence, then $V(x)$ is a fractal sequence. If x is a signature sequence, then $V(x) = x$.

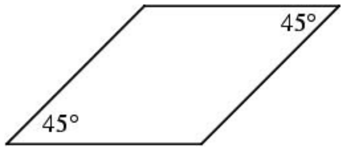
Loxodrome



A path, also known as a rhumb line, which cuts a meridian on a given surface at any constant angle but a right angle. If the surface is a sphere, the loxodrome is a spherical spiral. The loxodrome is the path taken when a compass is kept pointing in a constant direction. It is a straight line on a Mercator projection or a logarithmic spiral on a polar projection (Steinhaus 1983, pp. 218–19). The loxodrome is *not* the shortest distance between two points on a sphere.

See also Great Circle, Sphere, Spherical Spiral

References

Steinhaus, H. *Mathematical Snapshots, 3rd ed.* New York: Dover, pp. 217–21, 1999.

Lozenge

An equilateral parallelogram whose acute angles are 45°. Sometimes, the restriction to 45° is dropped, and it is required only that two opposite angles are acute and the other two obtuse. The term rhombus is commonly used for an arbitrary equilateral parallelogram.

See also Kite, Parallelogram, Quadrilateral, Rhombus

Lozenge Method

A method for constructing magic squares of odd order.

See also MAGIC SQUARE

Lozi Map

A 2-D map similar to the HÉNON MAP which is given by the equations

$$x_{n+1} = 1 - \alpha|x_n| + y_n$$
$$y_{n+1} = \beta x_n.$$

See also HÉNON MAP

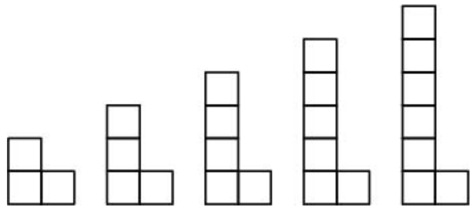
Lp'-Balance Theorem



If every component L of $X/O_{p'}(X)$ satisfies the "Schreler property," then

$$L_{p'}(Y) \leq L_{p'}(X)$$

for every p-local SUBGROUP Y of X, where $L_{p'}$ is the P-LAYER.

See also P-LAYER, SUBGROUP

L-Polyomino

The order $n \geq 2$ L-polyomino consists of a vertical line of n SQUARES with a single additional SQUARE attached at the bottom.

See also L-POLYOMINO, SKEW POLYOMINO, SQUARE, SQUARE POLYOMINO, STRAIGHT POLYOMINO

Lp-Space

The set of L^p-functions generalizes L2-SPACE. Instead of SQUARE INTEGRABLE, the MEASURABLE FUNCTION f must be p-integrable for f to be in L^p.

On a MEASURE SPACE X, the L^p norm of a function f is

$$\|f\|_{L^p} = \left(\int_X |f|^p\right)^{1/p}.$$

The L^p-functions are the functions for which this integral converges. For $p \neq 2$, the space of L^p-functions is a BANACH SPACE which is not a HILBERT SPACE.

The L^p-space on $\mathbb{R}^n$, and in most other cases, is the COMPLETION of the continuous functions with COMPACT SUPPORT using the L^p norm. As in the case of an L2-SPACE, an L^p-function is really an equivalence class of functions which agree ALMOST EVERYWHERE. It is possible for a sequence of functions f_n to converge in L^p but not in $L^{p'}$ for some other p', e.g., $f_n = (1+x^2)^{-1/2-1/n}$ converges in $L^2(\mathbb{R})$ but not $L^1(\mathbb{R})$. However, if a sequence converges in L^p and in $L^{p'}$, then its limit must be the same in both spaces.

For $p > 1$, the DUAL SPACE to L^p is given by integrating against functions in L^q, where $1/p + 1/q = 1$. This makes sense because of HÖLDER'S INEQUALITY FOR INTEGRALS. In particular, the only L^p-space which is SELF-DUAL is L^2.

While the use of L^p functions is not as common as L^2, they are very important in ANALYSIS and PARTIAL DIFFERENTIAL EQUATIONS. For instance, some OPERATORS are only BOUNDED in L^p for some $p > 2$.

Lucas Correspondence Theorem

Let p be PRIME and

$$r = r_m p^m + \ldots + r_1 p + r_0 \quad (0 \leq r_i < p) \tag{1}$$

$$k = k_m p^m + \ldots + k_1 p + k_0 \quad (0 \leq k_i < p), \tag{2}$$

then

$$\binom{r}{k} = \prod_{i=0}^{m} \binom{r_i}{k_i} (\mathrm{mod}\ p). \tag{3}$$

This is proved in Fine (1947).

Lucas-Lehmer Residue

LUCAS-LEHMER TEST

Lucas-Lehmer Test

A MERSENNE NUMBER M_p is prime IFF M_p divides s_{p-2}, where $s_0 \equiv 4$ and

$$s_i \equiv s_{i-1}^2 - 2 (\mathrm{mod}\ 2^p - 1) \tag{1}$$

for $i \geq 1$. The first few terms of this series are 4, 14, 194, 37634, 1416317954, ... (Sloane's A003010). The remainder when s_{p-2} is divided by M_p is called the LUCAS-LEHMER RESIDUE for p. The LUCAS-LEHMER RESIDUE is 0 IFF M_p is PRIME. This test can also be extended to arbitrary INTEGERS.

A generalized version of the Lucas-Lehmer test lets

$$N + 1 = \prod_{j=1}^{n} q_j^{\beta_j}, \tag{2}$$

with q_j the distinct PRIME FACTORS, and β_j their respective POWERS. If there exists a LUCAS SEQUENCE U_ν such that

$$\mathrm{GCD}(U_{(N+1)/q_j}, N) = 1 \tag{3}$$

for $j = 1, \ldots, n$ and

$$U_{N+1} \equiv 0 \ (\mathrm{mod}\ N), \tag{4}$$

then N is a PRIME. The test is particularly simple for MERSENNE NUMBERS, yielding the conventional Lucas-Lehmer test.

Lucas' Married Couples Problem

MARRIED COUPLES PROBLEM

Lucas Number

The numbers produced by the V recurrence in the LUCAS SEQUENCE with $(P, Q) = (1, -1)$ are called Lucas numbers. They are the companions to the FIBONACCI NUMBERS F_n and satisfy the same recurrence

$$L_n = L_{n-1} + L_{n-2}, \tag{1}$$

where $L_1 = 1$, $L_2 = 3$. The first few are 1, 3, 4, 7, 11, 18, 29, 47, 76, 123, ... (Sloane's A000204).

The analog of BINET'S FIBONACCI NUMBER FORMULA for Lucas numbers is

$$L_n = \left(\frac{1+\sqrt{5}}{2}\right)^n + \left(\frac{1-\sqrt{5}}{2}\right)^n. \tag{2}$$

Another formula is

$$L_n = [\phi^n], \tag{3}$$

where ϕ is the GOLDEN RATIO and $[x]$ denotes the NINT function. Given L_n,

$$L_{n+1} = \left\lfloor \frac{L_n(1+\sqrt{5})+1}{2} \right\rfloor, \tag{4}$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION,

$$L_n^2 - L_{n-1} L_{n+1} = 5(-1)^n, \tag{5}$$

and

$$\sum_{k=0}^{n} L_k^2 = L_n L_{n+1} - 2. \tag{6}$$

The Lucas numbers obey the negation formula

$$L_{-n} = (-1)^n L_n, \tag{7}$$

the addition formula

$$L_{m+n} = \tfrac{1}{2}(5F_m F_n + L_m L_n), \tag{8}$$

where F_n is a FIBONACCI NUMBER, the subtraction formula

$$L_{m-n} = \tfrac{1}{2}(-1)(L_m L_n - 5F_m F_n), \tag{9}$$

the fundamental identity

$$L_n^2 - 5F_n^2 = 4(-1)^n, \tag{10}$$

conjugation relation

$$L_n = F_{n-1} + F_{n+1}, \tag{11}$$

successor relation

$$L_{n+1} = \tfrac{1}{2}(5F_n + L_n), \tag{12}$$

double-angle formula

$$L_{2n} = \tfrac{1}{2}(5F_n^2 + L_n^2), \tag{13}$$

multiple-angle recurrence

$$L_{kn} = L_k L_{k(n-1)} - (-1)^k L_{k(n-2)}, \tag{14}$$

multiple-angle formulas

$$L_{kn} = \frac{1}{2^{k-1}} \sum_{i=0}^{\lfloor k/2 \rfloor} \binom{k}{2i} 5^i F_n^{2i} L_n^{k-2i} \tag{15}$$

$$= \sum_{i=0}^{\lfloor k/2 \rfloor} \frac{k}{k-i} \binom{k-i}{i} (-1)^{i(n+1)} L_n^{k-2i} \tag{16}$$

$$= \begin{cases} \sum_{i=0}^{k/2} \frac{k}{k-i} \binom{k-i}{i} (-1)^{in} 5^{k/2-i} F_n^{k-2i} & \text{for } k \text{ even} \\ L_n \sum_{i=0}^{\lfloor k/2 \rfloor} \binom{k-1-i}{i} (-1)^{in} 5^{\lfloor k/2 \rfloor - i} F_n^{k-1-2i} & \text{for } k \text{ odd} \end{cases} \tag{17}$$

$$= \sum_{i=0}^{k} \binom{k}{i} L_i F_n^i F_{n-1}^{k-i}, \tag{18}$$

product expansions

$$F_m L_n = F_{m+n} + (-1)^n F_{m-n} \tag{19}$$

and

$$F_m F_n = \tfrac{1}{5}[L_{m+n} - (-1)^n L_{m-n}], \tag{20}$$

square expansion,

$$L_n^2 = L_{2n} - 2(-1)^n, \tag{21}$$

and power expansion

$$L_n^k = \frac{1}{2} \sum_{i=0}^{k} \binom{k}{i} (-1)^{in} L_{(k-2i)n}. \tag{22}$$

The Lucas numbers satisfy the power recurrence

$$\sum_{j=0}^{t+1} (-1)^{j(j+1)/2} \begin{bmatrix} t+1 \\ j \end{bmatrix}_F L_{n-j}^t = 0, \tag{23}$$

where $\begin{bmatrix} a \\ b \end{bmatrix}_F$ is a FIBONACCI COEFFICIENT, the reciprocal sum

$$\sum_{k=1}^{n} \frac{(-1)^k}{L_k L_{k+a}} = \frac{F_n}{F_a} \sum_{k=1}^{a} \frac{(-1)^k}{L_k L_{k+n}}, \tag{24}$$

the convolution

$$\sum_{k=0}^{n} L_k L_{n-k} = (n+2)L_n + F_n, \tag{25}$$

the partial fraction decomposition

$$-\frac{5}{L_{n+a} L_{n+b} L_{n+c}} = \frac{A}{L_{n+a}} + \frac{B}{L_{n+b}} + \frac{C}{L_{n+c}}, \tag{26}$$

where

$$A = \frac{(-1)^{n-a}}{F_{b-a} F_{c-a}} \tag{27}$$

$$B = \frac{(-1)^{n-b}}{F_{c-b} F_{a-b}} \tag{28}$$

$$C = \frac{(-1)^{n-c}}{F_{a-c} F_{b-c}}, \tag{29}$$

and the summation formula

$$\sum_{k=0}^{n} x^k L_{ak+b} = \frac{g(n+1) - g(0)}{1 - L_a x + (-1)^a x^2}, \tag{30}$$

where

$$g(n) = (-1)^a L_{a(n-1)+b} x^{n+1} - L_{an+b} x^n. \tag{31}$$

Let p be a PRIME > 3 and k be a POSITIVE INTEGER. Then L_{2p^k} ends in a 3 (Honsberger 1985, p. 113). Analogs of the Cesàro identities for FIBONACCI NUMBERS are

$$\sum_{k=0}^{n} \binom{n}{k} L_k = L_{2n} \tag{32}$$

$$\sum_{k=0}^{n} \binom{n}{k} 2^k L_k = L_{3n}, \tag{33}$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT.

$L_n | F_m$ (L_n DIVIDES F_m) IFF n DIVIDES into m an EVEN number of times. $L_n | L_m$ IFF n divides into m an ODD number of times. $2^n L_n$ always ends in 2 (Honsberger 1985, p. 137).

Defining

$$D_n \equiv \begin{vmatrix} 3 & i & 0 & 0 & \cdots & 0 & 0 \\ i & 1 & i & 0 & \cdots & 0 & 0 \\ 0 & i & 1 & i & \cdots & 0 & 0 \\ 0 & 0 & i & 1 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & 0 & \cdots & 1 & i \\ 0 & 0 & 0 & 0 & 0 & i & 1 \end{vmatrix} = L_{n+1} \quad (34)$$

gives

$$D_n = D_{n-1} + D_{n-2} \quad (35)$$

(Honsberger 1985, pp. 113–14).

The number of ways of picking a set (including the EMPTY SET) from the numbers 1, 2, ..., n without picking two consecutive numbers (where 1 and n are now consecutive) is L_n (Honsberger 1985, p. 122).

The only SQUARE NUMBERS in the Lucas sequence are 1 and 4, as proved by John H. E. Cohn (Alfred 1964). The only TRIANGULAR Lucas numbers are 1, 3, and 5778 (Ming 1991). The only Lucas CUBIC NUMBER is 1. The first few Lucas PRIMES L_n occur for $n = 2$, 4, 5, 7, 8, 11, 13, 16, 17, 19, 31, 37, 41, 47, 53, 61, 71, 79, 113, 313, 353, ... (Dubner and Keller 1999, Sloane's A001606).

Lucas Polynomial

The w POLYNOMIALS obtained by setting $p(x) = x$ and $q(x) = 1$ in the LUCAS POLYNOMIAL SEQUENCE. The first few are

$$F_1(x) = x$$

$$F_2(x) = x^2 + 2$$

$$F_3(x) = 3x^3 + 3x$$

$$F_4(x) = x^4 + 4x^2 + 2$$

$$F_5(x) = x^5 + 5x^3 + 5x.$$

The corresponding W POLYNOMIALS are called FIBONACCI POLYNOMIALS. The Lucas polynomials satisfy

$$L_n(1) = L_n,$$

where the L_ns are LUCAS NUMBERS.

See also FIBONACCI POLYNOMIAL, LUCAS NUMBER, LUCAS POLYNOMIAL SEQUENCE

Lucas Polynomial Sequence

A pair of generalized POLYNOMIALS which generalize the LUCAS SEQUENCE to POLYNOMIALS is given by

$$W_n^k(x) = \frac{\Delta^k(x)[a^n(x) - (-1)^k b^n(x)]}{\Delta(x)} \quad (1)$$

$$w_n^k(x) = \Delta^k(x)\left[a^n(x) + (-1)^k b^n(x)\right], \quad (2)$$

where

$$a(x) + b(x) = p(x) \quad (3)$$

$$a(x)b(x) = -q(x) \quad (4)$$

$$a(x) - b(x) = \sqrt{p^2(x) + 4q(x)} \equiv \Delta(x) \quad (5)$$

(Horadam 1996). Setting $n = 0$ gives

$$W_0^k(x) = \Delta^k(x)\frac{1 - (-1)^k}{\Delta(x)} \quad (6)$$

$$w_0^k(x) = \Delta^k(x)[1 + (-1)^k], \quad (7)$$

giving

$$W_0^0(x) = 0 \quad (8)$$

$$w_0^0(x) = 2. \quad (9)$$

The sequences most commonly considered have $k = 0$, giving

$$W_n(x) \equiv W_n^0(x) = \frac{a^n(x) - b^n(x)}{a(x) - b(x)} \quad (10)$$

$$= \frac{\left[p(x) + \sqrt{p^2(x) + 4q(x)}\right]^n + \left[p(x) - \sqrt{p^2(x) + 4q(x)}\right]^n}{2^n \sqrt{p^2(x) + 4q^2(x)}} \quad (11)$$

$$w_n(x) \equiv w_n^0(x) = a^n(x) + b^n(x) \quad (12)$$

$$\frac{\left[p(x) + \sqrt{p^2(x) + 4q(x)}\right]^n + \left[p(x) + \sqrt{p^2(x) + 4q(x)}\right]^n}{2^n}. \quad (13)$$

The w polynomials satisfy the RECURRENCE RELATION

$$w_n(x) = p(x)w_{n-1}(x) + q(x)w_{n-2}(x). \quad (14)$$

Special cases of the W and w polynomials are given in the following table.

$p(x)$	$q(x)$	Polynomial 1	Polynomial 2
x	1	FIBONACCI $F_n(x)$	LUCAS $L_n(x)$
$2x$	1	PELL $P_n(x)$	PELL-LUCAS $Q_n(x)$
1	$2x$	JACOBSTHAL $J_n(x)$	JACOBSTHAL $j_n(x)$
$3x$	-2	FERMAT $\mathscr{F}_n(x)$	FERMAT-LUCAS $f_n(x)$
$2x$	-1	CHEBYSHEV POLYNOMIAL OF THE SECOND KIND $U_{n-1}(x)$	CHEBYSHEV POLYNOMIAL OF THE FIRST KIND $2T_n(x)$

See also CHEBYSHEV POLYNOMIAL OF THE FIRST KIND, CHEBYSHEV POLYNOMIAL OF THE SECOND KIND, FERMAT POLYNOMIAL, FIBONACCI POLYNOMIAL, JACOBSTHAL POLYNOMIAL, LUCAS POLYNOMIAL, LUCAS SEQUENCE, PELL POLYNOMIAL

Lucas Pseudoprime

When P and Q are INTEGERS such that $D = P^2 - 4Q \neq 0$, define the LUCAS SEQUENCE $\{U_k\}$ by

$$U_k = \frac{a^k - b^k}{a - b}$$

for $k \geq 0$, with a and b the two ROOTS of $x^2 - Px + Q = 0$. Then define a Lucas pseudoprime as an ODD COMPOSITE number n such that $n \nmid Q$, the JACOBI SYMBOL $(D/n) = -1$, and $n | U_{n+1}$.

There are no EVEN Lucas pseudoprimes (Bruckman 1994). The first few Lucas pseudoprimes are 705, 2465, 2737, 3745, ... (Sloane's A005845).

See also EXTRA STRONG LUCAS PSEUDOPRIME, LUCAS SEQUENCE, PSEUDOPRIME, STRONG LUCAS PSEUDOPRIME

Lucas Sequence

Let P, Q be POSITIVE INTEGERS. The ROOTS of

$$x^2 - Px + Q = 0 \quad (1)$$

are

$$a \equiv \tfrac{1}{2}\left(P + \sqrt{D}\right) \quad (2)$$

$$b \equiv \tfrac{1}{2}\left(P - \sqrt{D}\right), \quad (3)$$

where

$$D \equiv P^2 - 4Q, \quad (4)$$

so

$$a + b = P \quad (5)$$

$$ab = \tfrac{1}{4}(P^2 - D) = Q \quad (6)$$

$$a - b = \sqrt{D}. \quad (7)$$

Then define

$$U_n(P, Q) \equiv \frac{a^n - b^n}{a - b} \quad (8)$$

$$V_n(P, Q) \equiv a^n + b^n. \quad (9)$$

The first few values are therefore

$$U_0(P, Q) = 0 \quad (10)$$

$$U_1(P, Q) = 1 \quad (11)$$

$$V_0(P, Q) = 2 \quad (12)$$

$$V_1(P, Q) = P. \quad (13)$$

The sequences

$$U(P, Q) = \{U_n(P, Q) : n \geq 1\} \quad (14)$$

$$V(P, Q) = \{V_n(P, Q) : n \geq 1\} \quad (15)$$

are called Lucas sequences, where the definition is usually extended to include

$$U_{-1} = \frac{a^{-1} - b^{-1}}{a - b} = \frac{-1}{ab} = -\frac{1}{Q}. \quad (16)$$

For $(P, Q) = (1, -1)$, the U_n are the FIBONACCI NUM-

BERS and V_n are the LUCAS NUMBERS. For $(P, Q) = (2, -1)$, the PELL NUMBERS and Pell-Lucas numbers are obtained. $(P, Q) = (1, -2)$ produces the JACOBSTHAL NUMBERS and Pell-Jacobsthal Numbers.

The Lucas sequences satisfy the general RECURRENCE RELATIONS

$$U_{m+n} = \frac{a^{m+n} - b^{m+n}}{a - b}$$

$$= \frac{(a^m - b^m)(a^n + b^n)}{a - b} - \frac{a^n b^n (a^{m-n} - b^{m-n})}{a - b}$$

$$= U_m V_n - a^n b^n U_{m-n} \quad (17)$$

$$V_{m+n} = a^{m+n} + b^{m+n}$$

$$= (a^m + b^m)(a^n + b^n) - a^n b^n (a^{m-n} + b^{m-n})$$

$$= V_m V_n - a^n b^n V_{m-n}. \quad (18)$$

Taking $n = 1$ then gives

$$U_m(P, Q) = PU_{m-1}(P, Q) - QU_{m-2}(P, Q) \quad (19)$$

$$V_m(P, Q) = PV_{m-1}(P, Q) - QV_{m-2}(P, Q). \quad (20)$$

Other identities include

$$U_{2n} = U_n V_n \quad (21)$$

$$U_{2n+1} = U_{n+1} V_n - Q^n \quad (22)$$

$$V_{2n} = V_n^2 - 2(ab)^n = V_n^2 - 2Q^n \quad (23)$$

$$V_{2n+1} = V_{n+1} V_n - PQ^n. \quad (24)$$

These formulas allow calculations for large n to be decomposed into a chain in which only four quantities must be kept track of at a time, and the number of steps needed is $\sim \lg n$. The chain is particularly simple if n has many 2s in its factorization.

The Us in a Lucas sequence satisfy the CONGRUENCE

$$U_{p^{n-1}[p-(D/p)]} \equiv 0 \pmod{p^n} \quad (25)$$

if

$$\mathrm{GCD}(2QcD, p) = 1, \quad (26)$$

where

$$P^2 - 4Q^2 = c^2 D. \quad (27)$$

This fact is used in the proof of the general LUCAS-LEHMER TEST.

Lucas's Theorem

Let $n \geq 3$ be a SQUAREFREE integer, and $\Phi_n(z)$ a CYCLOTOMIC POLYNOMIAL. Then

$$\Phi_n(z) = U_n^2(z) - (-1)^{(n-1)/2} nzV_n^2(z), \quad (1)$$

where $U_n(z)$ and $V_n(z)$ are INTEGER POLYNOMIALS of degree $\phi(n)/2$ and $\phi(n)/2 - 1$, respectively. This identity can be expressed as

$$\begin{cases} \Phi_n((-1)^{(n-1)/2} z) = C_n^2(z) - nzD_n^2(z) & \text{for } n \text{ odd} \\ \Phi_{n/2}(-z^2) = C_n^2(z) - nzD_n^2(z) & n = 4k+2 \\ \Phi_1(-z^2) = C_2^2(z) - 2zD_2^2(z) & \text{for } n = 2, \end{cases} \quad (2)$$

with $C_n(z)$ and $D_n(z)$ SYMMETRIC POLYNOMIALS. The following table gives the first few $C_n(z)$ and $D_n(z)$s (Riesel 1994, pp. 443–56).

n	$C_n(z)$	$D_n(z)$
2	$z + 1$	1
3	$z + 1$	1
5	$z^2 + 3z + 1$	$z + 1$
6	$z^2 + 3z + 1$	$z + 1$
7	$z^3 + 3z^2 + 3z + 1$	$z^2 + z + 1$
10	$z^4 + 5z^3 + 7z^2 + 5z + 1$	$z^3 + 2z^2 + 2z + 1$

Lucky Number

Write out all the ODD numbers: 1, 3, 5, 7, 9, 11, 13, 15, 17, 19, ... The first ODD number > 1 is 3, so strike out every third number from the list: 1, 3, 7, 9, 13, 15, 19, ... The first ODD number greater than 3 in the list is 7, so strike out every seventh number: 1, 3, 7, 9, 13, 15, 21, 25, 31, ...

Numbers remaining after this procedure has been carried out completely are called lucky numbers. The first few are 1, 3, 7, 9, 13, 15, 21, 25, 31, 33, 37, ... (Sloane's A000959). Many asymptotic properties of the PRIME NUMBERS are shared by the lucky numbers. The asymptotic density is $1/\ln N$, just as the PRIME

NUMBER THEOREM, and the frequency of TWIN PRIMES and twin lucky numbers are similar. A version of the GOLDBACH CONJECTURE also seems to hold.

It therefore appears that the SIEVING process accounts for many properties of the PRIMES.

Lucky Number of Euler

A number p such that the PRIME-GENERATING POLYNOMIAL

$$n^2 - n + p$$

is PRIME for $n = 0, 1, \ldots, p-2$. Such numbers are related to the COMPLEX QUADRATIC FIELD in which the RING of INTEGERS is factorable. Specifically, the Lucky numbers of Euler (excluding the trivial case $p = 3$) are those numbers p such that the QUADRATIC FIELD $\mathbb{Q}(\sqrt{1-4p})$ has CLASS NUMBER 1 (Rabinowitz 1913, Le Lionnais 1983, Conway and Guy 1996).

As established by Stark (1967), there are only nine numbers $-d$ such that $h(-d) = 1$ (the HEEGNER NUMBERS -2, -3, -7, -11, -19, -43, -67, and -163), and of these, only 7, 11, 19, 43, 67, and 163 are of the required form. Therefore, the only Lucky numbers of Euler are 2, 3, 5, 11, 17, and 41 (Le Lionnais 1983, Sloane's A014556), and there does not exist a better PRIME-GENERATING POLYNOMIAL of Euler's form.

See also CLASS NUMBER, HEEGNER NUMBER, PRIME-GENERATING POLYNOMIAL

LUCY

A nonlinear DECONVOLUTION technique used in deconvolving images from the Hubble Space Telescope before corrective optics were installed.

See also DECONVOLUTION, MAXIMUM ENTROPY METHOD

LU Decomposition

A procedure for decomposing an $N \times N$ matrix A into a product of a LOWER TRIANGULAR MATRIX L and an UPPER TRIANGULAR MATRIX U,

$$\mathsf{LU} = \mathsf{A}. \tag{1}$$

LU decomposition is implemented in *Mathematica* as `LUDecomposition[`m`]`.

Written explicitly for a 3×3 MATRIX, the decomposition is

$$\begin{bmatrix} l_{11} & 0 & 0 \\ l_{21} & l_{22} & 0 \\ l_{31} & l_{32} & l_{33} \end{bmatrix} \begin{bmatrix} u_{11} & u_{12} & u_{13} \\ 0 & u_{22} & u_{23} \\ 0 & 0 & u_{33} \end{bmatrix} = \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix} \tag{2}$$

$$\begin{bmatrix} l_{11}u_{11} & l_{11}u_{12} & l_{11}u_{13} \\ l_{21}u_{11} & l_{21}u_{22} + l_{22}u_{22} & l_{21}u_{13} + l_{22}u_{23} \\ l_{31}u_{11} & l_{31}u_{12} + l_{32}u_{22} & l_{31}u_{13} + l_{32}u_{23} + l_{33}u_{23} \end{bmatrix} = \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix}. \tag{3}$$

This gives three types of equations

$$i < j \quad l_{i1}u_{1j} + l_{i2}u_{2j} + \ldots + l_{ii}u_{ij} = a_{ij} \tag{4}$$

$$i = j \quad l_{i1}u_{1j} + l_{i2}u_{2j} + \ldots + l_{ii}u_{jj} = a_{ij} \tag{5}$$

$$i > j \quad l_{i1}u_{1j} + l_{i2}u_{2j} + \ldots + l_{ij}u_{jj} = a_{ij}. \tag{6}$$

This gives N^2 equations for $N^2 + N$ unknowns (the decomposition is not unique), and can be solved using CROUT'S METHOD. To solve the MATRIX equation

$$\mathsf{A}\mathbf{x} = (\mathsf{LU})\mathbf{x} = \mathsf{L}(\mathsf{U}\mathbf{x}) = \mathbf{b}, \tag{7}$$

first solve $\mathsf{L}\mathbf{y} = \mathbf{b}$ for $\mathbf{y}$. This can be done by forward substitution

$$y_1 = \frac{b_1}{l_{11}} \tag{8}$$

$$y_i = \frac{1}{l_{ii}}\left(b_i - \sum_{j=1}^{i-1} l_{ij} y_j\right) \tag{9}$$

for $i = 2, \ldots, N$. Then solve $\mathsf{U}\mathbf{x} = \mathbf{y}$ for $\mathbf{x}$. This can be done by back substitution

$$x_N = \frac{y_N}{u_{NN}} \tag{10}$$

$$x_i = \frac{1}{u_{ii}}\left(y_i - \sum_{j=i+1}^{N} u_{ij} x_j\right) \tag{11}$$

for $i = N-1, \ldots, 1$.

Lune

A figure bounded by two circular arcs of unequal radii. Hippocrates of Chios squared the above left lune, as well as two others, in the fifth century BC. Two more squarable lunes were found by T. Clausen in the 19th century (Dunham 1990 attributes these discoveries to Euler in 1771). In the 20th century, N. G. Tschebatorew and A. W. Dorodnow proved that these are the only five squarable lunes (Shenitzer and Steprans 1994). The left lune above is squared as follows,

$$A_{\text{half small circle}} = \tfrac{1}{2}\pi\left(\frac{r}{\sqrt{2}}\right)^2 = \tfrac{1}{4}\pi r^2$$
$$A_{\text{lens}} = A_{\text{quarter big circle}} - A_{\text{triangle}}$$
$$= \tfrac{1}{4}\pi r^2 - \tfrac{1}{2}r^2$$
$$A_{\text{lune}} = A_{\text{half small circle}} - A_{\text{lens}} = \tfrac{1}{2}r^2$$
$$= A_{\text{triangle}},$$

so the lune and triangle have the same area. In the right figure, $A_1 + A_2 = A_\Delta$.

For the above lune,

$$A_{\text{lune}} = 2A_{\Delta OBC}.$$

Lyapunov Characteristic Exponent

The Lyapunov characteristic exponent [LCE] gives the rate of exponential divergence from perturbed initial conditions. To examine the behavior of an orbit around a point $\mathbf{X}^*(t)$, perturb the system and write

$$\mathbf{X}(t) = \mathbf{X}^*(t) + U(t), \tag{1}$$

where $U(t)$ is the average deviation from the unperturbed trajectory at time t. In a CHAOTIC region, the LCE σ is independent of $\mathbf{X}^*(0)$. It is given by the OSEDELEC THEOREM, which states that

$$\sigma_i = \lim_{t\to\infty} \frac{1}{t} \ln|\mathbf{U}(t)|. \tag{2}$$

For an n-dimensional mapping, the Lyapunov characteristic exponents are given by

$$\sigma_i = \lim_{N\to\infty} \ln|\lambda_i(N)| \tag{3}$$

for $i = 1, ..., n$, where λ_i is the LYAPUNOV CHARACTERISTIC NUMBER.

One Lyapunov characteristic exponent is always 0, since there is never any divergence for a perturbed trajectory in the direction of the unperturbed trajectory. The larger the LCE, the greater the rate of exponential divergence and the wider the corresponding SEPARATRIX of the CHAOTIC region. For the STANDARD MAP, an analytic estimate of the width of the CHAOTIC zone by Chirikov (1979) finds

$$\delta I = Be^{-AK^{-1/2}}. \tag{4}$$

Since the Lyapunov characteristic exponent increases with increasing K, some relationship likely exists connecting the two. Let a trajectory (expressed as a MAP) have initial conditions $(x_0,\ y_0)$ and a nearby trajectory have initial conditions $(x',\ y') = (x_0 + dx,\ y_0 + dy)$. The distance between trajectories at iteration k is then

$$dk = \|(x' - x_0,\ y' - y_0)\|, \tag{5}$$

and the mean exponential rate of divergence of the trajectories is defined by

$$\sigma_1 = \lim_{k\to\infty} \frac{1}{k} \ln\left(\frac{d_k}{d_0}\right). \tag{6}$$

For an n-dimensional phase space (MAP), there are n Lyapunov characteristic exponents $\sigma_1 \geq \sigma_2 \geq \ldots > \sigma_n$.. However, because the largest exponent σ_1 will dominate, this limit is practically useful only for finding the largest exponent. Numerically, since d_k increases exponentially with k, after a few steps the perturbed trajectory is no longer nearby. It is therefore necessary to renormalize frequently every t steps. Defining

$$r_{kr} \equiv \frac{d_{kr}}{d_0}, \tag{7}$$

one can then compute

$$\sigma_1 = \lim_{k\to\infty} \frac{1}{nr} \sum_{k=1}^{n} \ln r_{kr}. \tag{8}$$

Numerical computation of the second (smaller) Lyapunov exponent may be carried by considering the evolution of a 2-D surface. It will behave as

$$e^{(\sigma_1+\sigma_2)t}, \tag{9}$$

so σ_2 can be extracted if σ_1 is known. The process may be repeated to find smaller exponents.

For HAMILTONIAN SYSTEMS, the LCEs exist in additive inverse pairs, so if σ is an LCE, then so is $-\sigma$. One LCE is always 0. For a 1-D oscillator (with a 2-D phase space), the two LCEs therefore must be $\sigma_1 = \sigma_2 = 0$, so the motion is QUASIPERIODIC and cannot be CHAOTIC. For higher order HAMILTONIAN SYSTEMS, there are always at least two 0 LCEs, but other LCEs may enter in plus-and-minus pairs l and $-l$. If they, too, are both zero, the motion is integrable and not CHAOTIC. If they are NONZERO, the POSITIVE LCE l results in an exponential separation of trajectories, which corresponds to a CHAOTIC region. Notice that it is not possible to have all LCEs NEGATIVE, which explains why convergence of orbits is never observed in HAMILTONIAN SYSTEMS.

Now consider a dissipative system. For an arbitrary n-D phase space, there must always be one LCE equal to 0, since a perturbation along the path results in no divergence. The LCEs satisfy $\Sigma_i\ \sigma_i < 0$. Therefore, for a 2-D phase space of a dissipative system, $\sigma_1 = 0,\ \sigma_2 < 0$. For a 3-D phase space, there are three possibilities:

1. (Integrable): $\sigma_1 = 0,\ \sigma_2 = 0,\ \sigma_3 < 0,$
2. (Integrable): $\sigma_1 = 0,\ \sigma_2,\ \sigma_3 < 0.,$
3. (CHAOTIC): $\sigma_1 = 0,\ \sigma_2 > 0,\ \sigma_3 < -\sigma_2 < 0.$

Lyapunov Characteristic Number

Given a LYAPUNOV CHARACTERISTIC EXPONENT σ_i, the corresponding Lyapunov characteristic number λ_i is defined as

$$\lambda_i \equiv e^{\sigma_i}. \tag{1}$$

For an n-dimensional linear MAP,

$$\mathbf{X}_{n+1} = \mathsf{M}\mathbf{X}_n. \tag{2}$$

The Lyapunov characteristic numbers $\lambda_1, \ldots, \lambda_n$ are the EIGENVALUES of the MAP MATRIX. For an arbitrary MAP

$$x_{n+1} = f_1(x_n,\ y_n) \tag{3}$$

$$y_{n+1} = f_2(x_n,\ y_n), \tag{4}$$

the Lyapunov numbers are the EIGENVALUES of the limit

$$\lim_{n\to\infty} [J(x_n,\ y_n)J(x_{n-1},\ y_{n-1})\cdots J(x_1,\ y_1)]^{1/n}, \tag{5}$$

where $J(x,\ y)$ is the JACOBIAN

$$J(x,\ y) \equiv \begin{vmatrix} \frac{\partial f_1(x,\ y)}{\partial x} & \frac{\partial f_1(x,\ y)}{\partial y} \\ \frac{\partial f_2(x,\ y)}{\partial x} & \frac{\partial f_2(x,\ y)}{\partial y} \end{vmatrix}. \tag{6}$$

If λ_i for all i, the system is not CHAOTIC. If $\lambda \neq 0$ and the MAP is AREA-PRESERVING (HAMILTONIAN), the product of EIGENVALUES is 1.

See also ADIABATIC INVARIANT, CHAOS, LYAPUNOV CHARACTERISTIC EXPONENT

Lyapunov Condition

If the third MOMENT exists for a STATISTICAL DISTRIBUTION of x_i and the LEBESGUE INTEGRAL is given by

$$r_n^3 = \sum_{i=1}^{n} \int_{-\infty}^{\infty} |x|^3\ dF_i(x),$$

then if

$$\lim_{n\to\infty} \frac{r_n}{s_n} = 0,$$

the CENTRAL LIMIT THEOREM holds.

See also CENTRAL LIMIT THEOREM

Lyapunov Dimension

For a 2-D MAP with $\sigma_2 > \sigma_1$,

$$d_{\text{Lya}} = 1 - \frac{\sigma_1}{\sigma_2},$$

where σ_n are the LYAPUNOV CHARACTERISTIC EXPONENTS.

Lyapunov Function

This entry contributed by MARTIN KELLER-RESSEL

A Lyapunov function is a SCALAR FUNCTION $V(y)$ defined on a region D that is continuous, positive definite (i.e., $V(0)=0$, $V(y)>0$ for all $y\neq 0$), and has continuous first-order PARTIAL DERIVATIVES at every point of D. The derivative of V with respect to the system $y'=f(y)$, written as $V^*(y)$ is defined as the DOT PRODUCT

$$V^*(y)=\nabla V(y)\cdot F(y).$$

The existence of a Lyapunov function for which $V^*(y)\leq 0$ on some region D containing the origin, guarantees the stability of the zero solution of $y'=f(y)$, while the existence of a Lyapunov function for which $V^*(y)$ is negative definite (i.e., $V^*(0)=0$, $V^*(y)<0$ for all $y\neq 0$) on some region D containing the origin guarantees the asymptotical stability of the zero solution of $y'=f(y)$

For example, given the system

$$y'=z$$

$$z'=-y-2z$$

and the Lyapunov function $V(y,\ z)=(y^2+z^2)/2$, we obtain

$$V^*(y,\ z)=yz+z(-y-2z)=-2z^2,$$

which is nonnegative on every region containing the origin, and thus the zero solution is stable.

Lyapunov's Second Theorem

If all the EIGENVALUES of a REAL MATRIX A have REAL PARTS, then to an arbitrary negative definite quadratic form $(\mathbf{x},\ \mathsf{W}\mathbf{x})$ with $\mathbf{x}=\mathbf{x}(t)$ there corresponds a positive definite quadratic form $(\mathbf{x},\ \mathsf{V}\mathbf{x})$ such that if one takes

$$\frac{dx}{dt}=\mathsf{A}\mathbf{Ax},$$

then $(\mathbf{x},\ \mathsf{V}\mathbf{x})$ and $(\mathbf{x},\ \mathsf{W}\mathbf{x})$ satisfy

$$\frac{d}{dt}(\mathbf{x},\ \mathsf{V}\mathbf{x})=(\mathbf{x},\ \mathsf{W}\mathbf{x}).$$

Macdonald's Constant-Term Conjecture

Macdonald's constant term conjectures are related to ROOT SYSTEMS of LIE ALGEBRAS (Macdonald 1982, Andrews 1986). They can be regarded as generalizations of DYSON'S CONJECTURE (Dyson 1962), its q-analog due to Andrews, and Mehta's conjecture (Mehta 1991). The simplest of these states that if R is a ROOT SYSTEM, then the constant term in $\Pi_{\alpha\in R}(1-e^{\alpha})^k$, where k is a NONNEGATIVE INTEGER, is $\Pi_{i=1}^{l}\binom{kd_l}{k}$, where the d_l are fixed integer parameters of the ROOT SYSTEM R corresponding to the fundamental invariants of the WEYL GROUP W of R (Andrews 1986, p. 41).

Opdam (1989) proved the $q=1$ case for all root systems. The general conjecture had remained "almost proved" for some time, since the infinite families were accomplished by Zeilberger-Bressoud (A_n), Kadell (B_n, D_n) Gustafson (BC_n, C_n), while the exceptional cases were done by Zeilberger and (independently) Habsieger (G_2), Zeilberger (G_2 dual), and Garvan and Gonnet (F_4 and F_4 dual), using Zeilberger's method. This left only the three root systems (E_6, E_7, E_8) which were infeasible to address using existing computers. In the meanwhile, however, Cherednik (1993) proved the constant term conjectures for all root systems using a methodology not dependent on classification.

A special case of the constant-term conjecture is given by the assertion that the constant term in

$$\prod_{1<i\neq j\leq n}\left(1-\frac{x_i}{x_j}\right)^k \tag{1}$$

is $(nk)!/(k!)^n$. Another special case asserts that the constant term in

$$\left[\prod_{i\leq\leq n}(x_i;\ q)_a(q/x_i;\ q)_a\right] \times\prod_{1\leq i\leq j\leq n}(x_ix_j;\ q)_b\left(\frac{q}{x_ix_j};\ q\right)_b\left(\frac{x_i}{x_j};\ q\right)_b\left(\frac{qx_j}{x_i};\ q\right)_b \tag{2}$$

is

$$\frac{(q;\ q)_{nb}}{[(q;\ q)_b]^n}\prod_{1\leq j\leq n-1}\frac{(q;\ q)_{2a+2jb}(q;\ q)_{2jb}}{(q;\ q)_{a+(n+j-1)n}(q;\ q)_{a+jb}} \tag{3}$$

(Andrews 1986, p. 41).

Macdonald's Plane Partition Conjecture

Macdonald's plane partition conjecture proposes a formula for the number of CYCLICALLY SYMMETRIC PLANE PARTITIONS (CSPPs) of a given integer whose YOUNG DIAGRAMS fit inside an $n\times n\times n$ box. Macdonald gave a product representation for the power series whose coefficients q^n were the number of such partitions of n.

Let $D(\pi)$ be the set of all integer points $(i,\ j,\ k)$ in the first OCTANT such that a PLANE PARTITION $\pi=(a_{ij})$ is defined and $1\leq k\leq a_{ij}$. Then π is said to be cyclically symmetric if $D(\pi)$ is invariant under the mapping $(i,\ j,\ k)\to(j,\ k,\ i)$. Let $M(m,\ n)$ be the number of cyclically symmetric partitions of n such that none of i, j, a_{ij} exceed m. Let $\mathfrak{B}_m$ be the box containing all integer points $(i,\ j,\ k)$ such that $1\leq i,\ j,\ k\leq m$, then $M(m,\ n)$ is the number of cyclically symmetric plane partitions of n such that $D(\pi)\subseteq\mathfrak{B}_m$. Now, let $\mathfrak{C}_m$ be the set of all the orbits in $\mathfrak{B}_m$. Finally, for each point $p=(i,\ j,\ k)$ in $\mathfrak{B}_m$, let its height

$$ht(p)=i+j+k-2 \tag{1}$$

and for each ξ in $\mathfrak{C}_m$, let $|\xi|$ be the number of points in ξ (either 1 or 3) and write

$$ht(\xi) = \sum_{p \in \xi} ht(p). \qquad (2)$$

Then Macdonald conjectured that

$$\sum_{n \geq 0} M(m,\ n) q^n = \prod_{\xi \in \mathfrak{C}_m} \frac{1 - q^{|\xi| + ht(\xi)}}{1 - q^{ht(\xi)}} \qquad (3)$$

$$= \prod_{i=1}^{m} \left[\frac{1 - q^{3i-1}}{1 - q^{3i-2}} \prod_{j=i}^{m} \frac{1 - q^{3(m+i+j-1)}}{1 - q^{3(2i+j-1)}} \right], \qquad (4)$$

(Mills *et al.* 1982, Macdonald 1995), where the latter form is due to Andrews (1979).

Andrews (1979) proved the $q = 1$ case, giving the total number of CSPPs fitting inside an $n \times n \times n$ box. The general case was proved by Mills *et al.* (1982).

Machin-Like Formulas

Machin-like formulas have the form

$$m \cot^{-1} u + n \cot^{-1} v = \tfrac{1}{4} k\pi, \qquad (1)$$

where u, v, and k are POSITIVE INTEGERS and m and n are NONNEGATIVE INTEGERS. Some such FORMULAS can be found by converting the INVERSE TANGENT decompositions for which $c_n \neq 0$ in the table of Todd (1949) to INVERSE COTANGENTS. However, this gives only Machin-like formulas in which the smallest term is ± 1.

Machin-like formulas can be derived by writing

$$\cot^{-1} z = \frac{1}{2i} \ln\left(\frac{z+i}{z-i}\right) \qquad (2)$$

and looking for a_k and u_k such that

$$\sum_k a_k \cot^{-1} u_k = \tfrac{1}{4}\pi, \qquad (3)$$

so

$$\prod_k \left(\frac{u_k + i}{u_k - i}\right)^{a_k} = e^{2\pi i/4} = i. \qquad (4)$$

Machin-like formulas exist IFF (4) has a solution in INTEGERS. This is equivalent to finding INTEGER values such that

$$(1-i)^k (u+i)^m (v+i)^n \qquad (5)$$

is REAL (Borwein and Borwein 1987, p. 345). An equivalent formulation is to find all integral solutions to one of

$$1 + x^2 = 2y^n \qquad (6)$$

$$1 + x^2 = y^n \qquad (7)$$

for $n = 3, 5, ...$

There are only four such FORMULAS,

$$\tfrac{1}{4}\pi = 4\tan^{-1}\left(\tfrac{1}{5}\right) - \tan^{-1}\left(\tfrac{1}{239}\right) \qquad (8)$$

$$\tfrac{1}{4}\pi = \tan^{-1}\left(\tfrac{1}{2}\right) + \tan^{-1}\left(\tfrac{1}{3}\right) \qquad (9)$$

$$\tfrac{1}{4}\pi = 2\tan^{-1}\left(\tfrac{1}{2}\right) - \tan^{-1}\left(\tfrac{1}{7}\right) \qquad (10)$$

$$\tfrac{1}{4}\pi = 2\tan^{-1}\left(\tfrac{1}{3}\right) + \tan^{-1}\left(\tfrac{1}{7}\right), \qquad (11)$$

known as MACHIN'S FORMULA, EULER'S MACHIN-LIKE FORMULA, HERMANN'S FORMULA, and HUTTON'S FORMULA. These follow from the identities

$$\left(\frac{5+i}{5-i}\right)^4 \left(\frac{239+i}{239-i}\right)^{-1} = i \qquad (12)$$

$$\left(\frac{2+i}{2-i}\right)\left(\frac{3+i}{3-i}\right) = i \qquad (13)$$

$$\left(\frac{2+i}{2-i}\right)\left(\frac{7+i}{7-i}\right)^{-1} = i \qquad (14)$$

$$\left(\frac{3+i}{3-i}\right)\left(\frac{7+i}{7-i}\right) = i. \qquad (15)$$

Machin-like formulas with two terms can also be

generated which do not have integral arc cotangent arguments such as Euler's

$$\tfrac{1}{4}\pi = 5\tan^{-1}\left(\tfrac{1}{7}\right) + 2\tan^{-1}\left(\tfrac{3}{79}\right) \tag{16}$$

(Wetherfield 1996), and which involve inverse SQUARE ROOTS, such as

$$\frac{\pi}{2} = 2\tan^{-1}\left(\frac{1}{\sqrt{2}}\right) + \tan^{-1}\left(\frac{1}{\sqrt{8}}\right). \tag{17}$$

Three-term Machin-like formulas include GAUSS'S MACHIN-LIKE FORMULA

$$\tfrac{1}{4}\pi = 12\cot^{-1}18 + 8\cot^{-1}57 - 5\cot^{-1}239, \tag{18}$$

STRASSNITZKY'S FORMULA

$$\tfrac{1}{4}\pi = \cot^{-1}2 + \cot^{-1}5 + \cot^{-1}8, \tag{19}$$

and the following,

$$\tfrac{1}{4}\pi = 6\cot^{-1}8 + 2\cot^{-1}57 + \cot^{-1}239 \tag{20}$$

$$\tfrac{1}{4}\pi = 4\cot^{-1}5 - 1\cot^{-1}70 + \cot^{-1}99 \tag{21}$$

$$\tfrac{1}{4}\pi = 1\cot^{-1}2 + 1\cot^{-1}5 + \cot^{-1}8 \tag{22}$$

$$\tfrac{1}{4}\pi = 8\cot^{-1}10 - 1\cot^{-1}239 - 4\cot^{-1}515 \tag{23}$$

$$\tfrac{1}{4}\pi = 5\cot^{-1}7 + 4\cot^{-1}53 + 2\cot^{-1}4443. \tag{24}$$

The first is due to Størmer, the second due to Rutherford, and the third due to Dase.

Using trigonometric identities such as

$$\cot^{-1}x = 2\cot^{-1}(2x) - \cot^{-1}\left(4x^3 + 3x\right), \tag{25}$$

it is possible to generate an infinite sequence of Machin-like formulas. Systematic searches therefore most often concentrate on formulas with particularly "nice" properties (such as "efficiency").

The efficiency of a FORMULA is the time it takes to calculate π with the POWER SERIES for arctangent

$$\pi = a_1\cot(b_1) + a_2\cot(b_2) + \ldots, \tag{26}$$

and can be roughly characterized using Lehmer's "measure" formula

$$e \equiv \sum \frac{1}{\log_{10} b_i}. \tag{27}$$

The number of terms required to achieve a given precision is roughly proportional to e, so lower e-values correspond to better sums. The best currently known efficiency is 1.51244, which is achieved by the 6-term series

$$\tfrac{1}{4}\pi = 183\cot^{-1}239 + 32\cot^{-1}1023 - 68\cot^{-1}5832 + 12\cot^{-1}110443 - 12\cot^{-1}4841182 - 100\cot^{-1}6826318 \tag{28}$$

discovered by C.-L. Hwang (1997). Hwang (1997) also discovered the remarkable identities

$$\begin{aligned}\tfrac{1}{4}\pi = {} & P\cot^{-1}2 - M\cot^{-1}3 + L\cot^{-1}5 + K\cot^{-1}7 \\ & + (N + K + L - 2M + 3P - 5)\cot^{-1}8 \\ & + (2N + M - P + 2 - L)\cot^{-1}18 \\ & - (2P - 3 - M + L + K - N)\cot^{-1}57 - N\cot^{-1}239,\end{aligned} \tag{29}$$

where K, L, M, N, and P are POSITIVE INTEGERS, and

$$\tfrac{1}{4}\pi = (N + 2)\cot^{-1}2 - N\cot^{-1}3 - (N + 1)\cot^{-1}N. \tag{30}$$

The following table gives the number $N(n)$ of Machin-like formulas of n terms in the compilation by Wetherfield and Hwang. Except for previously known identities (which are included), the criteria for inclusion are the following:

1. first term < 8 digits: measure < 1.8.
2. first term $= 8$ digits: measure < 1.9.
3. first term $= 9$ digits: measure < 2.0.
4. first term $= 10$ digits: measure < 2.0.

n	$N(n)$	min e
1	1	0
2	4	1.85113
3	106	1.78661
4	39	1.58604
5	90	1.63485
6	120	1.51244

Machin's Formula

$$\tfrac{1}{4}\pi = 4\tan^{-1}\left(\tfrac{1}{5}\right) - \tan^{-1}\left(\tfrac{1}{239}\right).$$

There are a whole class of MACHIN-LIKE FORMULAS with various numbers of terms (although only four such formulas with only two terms). The properties of these formulas are intimately connected with COTANGENT identities.

See also 239, GREGORY NUMBER, MACHIN-LIKE FORMULAS, PI

Mackey's Theorem

Let E and F be paired spaces with S a family of absolutely convex bounded sets of F such that the sets of S generate F and, if $B_1, B_2 \in S$, there exists a $B_3 \in S$ such that $B_3 \supset B_1$ and $B_3 \supset B_2$. Then the dual space of E_S is equal to the union of the weak completions of λB, where $\lambda > 0$ and $B \in S$.

A theorem which treats constructions of FIELDS of CHARACTERISTIC p.

See also CHARACTERISTIC (FIELD), FIELD

Maclaurin-Bézout Theorem

The Maclaurin-Bézout theorem says that two curves of degree n intersect in n^2 points, so two CUBICS intersect in nine points. This means that $n(n+3)/2$ points do not always uniquely determine a single curve of order n.

See also CRAMÉR-EULER PARADOX

Maclaurin-Cauchy Theorem

If $f(x)$ is positive and decreases to 0, then an EULER CONSTANT

$$\gamma_f = \lim_{n\to\infty}\left[\sum_{k=1}^{n} f(k) - \int_a^n f(x)\,dx\right]$$

can be defined. If $f(x) = 1/x$, then

$$\gamma = \lim_{n\to\infty}\left(\sum_{k=1}^{n}\frac{1}{k} - \int_1^n \frac{dx}{x}\right) = \lim_{n\to\infty}\left(\sum_{k=1}^{n}\frac{1}{k} - \ln n\right),$$

where γ is the EULER-MASCHERONI CONSTANT.

INTEGRAL TEST

Maclaurin Polynomial

MACLAURIN SERIES

Maclaurin Series

A series expansion of a function about 0,

$$f(x) = f(0) + f'(0)x + \frac{f''(0)}{2!}x^2 + \frac{f^{(3)}(0)}{3!}x^3 + \ldots + \frac{f^{(n)}(0)}{n!}x^n + \ldots, \quad (1)$$

named after the Scottish mathematician Maclaurin. Maclaurin series for common functions include

$$\frac{1}{1-x} = 1 + x + x^2 + x^3 + x^4 + x^5 + \ldots \quad \text{for } -1 < x < 1 \quad (2)$$

$$\operatorname{cn}(x,\ k) = 1 - \tfrac{1}{2}x^2 + \tfrac{1}{24}(1+4k^2)x^4 + \ldots \quad (3)$$

$$\cos x = 1 - \tfrac{1}{2}x^2 + \tfrac{1}{24}x^4 - \tfrac{1}{720}x^6 - \ldots \quad \text{for } -\infty < x < \infty \quad (4)$$

$$\cos^{-1} x = \tfrac{1}{2}\pi - x - \tfrac{1}{6}x^3 - \tfrac{3}{40}x^5 - \tfrac{5}{112}x^7 - \ldots \quad \text{for } -1 < x < 1 \quad (5)$$

$$\cosh x = 1 + \tfrac{1}{2}x^2 + \tfrac{1}{24}x^4 + \tfrac{1}{720}x^6 + \tfrac{1}{40{,}320}x^8 + \ldots \quad (6)$$

$$\cosh^{-1}(1+x) = \sqrt{2x}\left(1 - \tfrac{1}{2}x + \tfrac{3}{160}x^2 - \tfrac{5}{896}x^3 + \ldots\right) \quad (7)$$

$$\cot x = x^{-1} - \tfrac{1}{3}x - \tfrac{1}{45}x^3 - \tfrac{2}{945}x^5 - \tfrac{1}{4725}x^7 - \ldots \quad (8)$$

$$\cot^{-1} x = \tfrac{1}{2}\pi - x + \tfrac{1}{3}x^3 - \tfrac{1}{5}x^5 + \tfrac{1}{7}x^7 - \tfrac{1}{9}x^9 + \ldots \quad (9)$$

$$\cot^{-1}\left(\frac{1}{x}\right) = x - \tfrac{1}{3}x^3 + \tfrac{1}{5}x^5 - \tfrac{1}{7}x^7 + \tfrac{1}{9}x^9 + \ldots \quad (10)$$

$$\coth x = x^{-1} + \tfrac{1}{3}x - \tfrac{1}{45}x^4 + \tfrac{2}{945}x^5 - \tfrac{1}{4725}x^7 + \ldots \quad (11)$$

$$\coth^{-1}(1+x) = \tfrac{1}{2}\ln 2 - \tfrac{1}{2}\ln x + \tfrac{1}{4}x - \tfrac{1}{16}x^2 + \ldots \quad (12)$$

$$\ln(1+x) = x - \tfrac{1}{2}x^2 + \tfrac{1}{3}x^3 - \tfrac{1}{4}x^4 + \ldots \quad \text{for } -1 < x < 1 \quad (20)$$

$$\ln\left(\frac{1+x}{1-x}\right) = 2x + \tfrac{2}{3}x^3 + \tfrac{2}{5}x^5 + \tfrac{2}{7}x^7 + \ldots \quad \text{for } -1 < x < 1 \quad (21)$$

$$\sec x = 1 + \tfrac{1}{2}x^2 + \tfrac{5}{24}x^4 + \tfrac{61}{720}x^6 + \tfrac{277}{8064}x^8 + \ldots \quad (22)$$

$$\operatorname{sech} x = 1 - \tfrac{1}{2}x^2 + \tfrac{5}{24}x^4 - \tfrac{61}{720}x^6 + \tfrac{277}{8064}x^8 + \ldots \quad (23)$$

$$\operatorname{sech}^{-1} x = \ln 2 - \ln x - \tfrac{1}{4}x^2 - \tfrac{3}{32}x^4 - \ldots \quad (24)$$

$$\sin x = x - \tfrac{1}{6}x^3 + \tfrac{1}{120}x^5 - \tfrac{1}{5040}x^7 + \ldots \quad \text{for } -\infty < x < \infty \quad (25)$$

$$\sin^{-1} x = x + \tfrac{1}{6}x^3 + \tfrac{3}{40}x^5 + \tfrac{5}{112}x^7 + \tfrac{35}{112}x^9 + \ldots \quad (26)$$

$$\sinh x = x + \tfrac{1}{6}x^3 + \tfrac{1}{120}x^5 + \tfrac{1}{5040}x^7 + \tfrac{1}{362{,}880}x^9 + \ldots \quad (27)$$

$$\sinh^{-1} x = x - \tfrac{1}{6}x^3 + \tfrac{3}{40}x^5 - \tfrac{5}{112}x^7 + \tfrac{35}{1152}x^9 - \ldots \quad (28)$$

$$\operatorname{sn}(x,\ k) = x - \tfrac{1}{6}(1+k^2)x^3 + \tfrac{1}{120}(1+14k^2+k^4)x^5 + \ldots \quad (29)$$

$$\tan x = x + \tfrac{1}{3}x^3 + \tfrac{2}{15}x^5 + \tfrac{17}{315}x^7 + \tfrac{62}{2835}x^9 + \ldots \quad (30)$$

$$\tan^{-1} x = x - \tfrac{1}{3}x^3 + \tfrac{1}{5}x^5 - \tfrac{1}{7}x^7 + \ldots \quad \text{for } -1 < x < 1 \quad (31)$$

$$\tan^{-1}(1+x) = \tfrac{1}{4}\pi + \tfrac{1}{2}x - \tfrac{1}{4}x^2 + \tfrac{1}{12}x^3 + \tfrac{1}{40}x^5 + \ldots \quad (32)$$

$$\tanh x = x - \tfrac{1}{3}x^3 + \tfrac{2}{15}x^5 - \tfrac{17}{315}x^7 + \tfrac{62}{2835}x^9 + \ldots \quad (33)$$

$$\tanh^{-1} x = x + \tfrac{1}{3}x^3 + \tfrac{1}{5}x^5 + \tfrac{1}{7}x^7 + \tfrac{1}{9}x^9 + \ldots \quad (34)$$

The explicit forms for some of these are

$$\frac{1}{1-x} = \sum_{n=0}^{\infty} x^n \quad (35)$$

$$\cos x = \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n)!}x^{2n} \quad (36)$$

$$\cosh x = \sum_{n=0}^{\infty} \frac{1}{(2n)!}x^{2n} \quad (37)$$

$$\csc x = \sum_{n=0}^{\infty} \frac{(-1)^{n+1}2(2^{2n-1}-1)B_{2n}}{(2n)!}x^{2n-1} \quad (38)$$

$$e^x = \sum_{n=0}^{\infty} \frac{1}{n!} x^n \quad (39)$$

$$\ln(1+x) = \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n} x^n \quad (40)$$

$$\ln\left(\frac{1+x}{1-x}\right) = \sum_{n=1}^{\infty} \frac{2}{(2n-1)} x^{2n-1} \quad (41)$$

$$\sec x = \sum_{n=0}^{\infty} \frac{(-1)^n E_{2n}}{(2n)!} x^{2n} \quad (42)$$

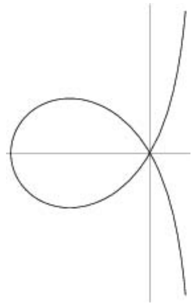
$$\sin x = \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n+1)!} x^{2n+1} \quad (43)$$

$$\sinh x = \sum_{n=0}^{\infty} \frac{1}{(2n+1)!} x^{2n+1} \quad (44)$$

$$\tan x = \sum_{n=0}^{\infty} \frac{(-1)^n 2^{2n+2}(2^{2n+2}-1)B_{2n+2}}{(2n+2)!} x^{2n+1} \quad (45)$$

$$\tan^{-1} x = \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{(2n-1)} x^{2n-1} \quad (46)$$

$$\tanh^{-1} x = \sum_{n=1}^{\infty} \frac{1}{2n-1} x^{2n-1}, \quad (47)$$



where B_n are BERNOULLI NUMBERS and E_n are EULER NUMBERS.

Maclaurin Trisectrix

A curve first studied by Colin Maclaurin in 1742. It was studied to provide a solution to one of the GEOMETRIC PROBLEMS OF ANTIQUITY, in particular TRISECTION of an ANGLE, whence the name trisectrix.

The Maclaurin trisectrix is an ANALLAGMATIC CURVE, and the origin is a CRUNODE.

The Maclaurin trisectrix has CARTESIAN equation

$$y^2 = \frac{x^2(x+3a)}{a-x}, \quad (1)$$

or the PARAMETRIC EQUATIONS

$$x = a\frac{t^2-3}{t^2+1} \quad (2)$$

$$y = a\frac{t(t^2-3)}{t^2+1}. \quad (3)$$

The ASYMPTOTE has equation $x = a$, and the center of the loop is at $(-2a, 0)$. If P is a point on the loop so that the line CP makes an ANGLE of 3α with the negative Y-AXIS, then the line OP will make an ANGLE of α with the negative Y-AXIS.

The Maclaurin trisectrix is sometimes defined instead as

$$x(x^2+y^2) = a(y^2-3x^2) \quad (4)$$

$$y^2 = \frac{x^2(3a+x)}{a-x} \quad (5)$$

$$r = \frac{2a\sin(3\theta)}{\sin(2\theta)}. \quad (6)$$

Another form of the equation is the POLAR EQUATION

$$r = a\sec\left(\tfrac{1}{3}\theta\right), \quad (7)$$

where the origin is inside the loop and the crossing point is on the NEGATIVE X-AXIS.

The tangents to the curve at the origin make angles of $\pm 60°$ with the X-AXIS. The AREA of the loop is

$$A_{\text{loop}} = 3\sqrt{3}a^2, \quad (8)$$

and the NEGATIVE x-intercept is $(-3a, 0)$ (MacTutor Archive).

The Maclaurin trisectrix is the PEDAL CURVE of the PARABOLA where the PEDAL POINT is taken as the reflection of the FOCUS in the DIRECTRIX.

Macron

A macron is a BAR placed over a single symbol or character, such as $\bar{x}$. The symbol $\bar{z}$ is sometimes used to denote the following operations.

1. The COMPLEX CONJUGATE.
2. NEGATION of a logical expression.
3. Infrequently, ADJOINT operator.

A bar placed over multiple symbols or characters is called a VINCULUM.

Madelung Constants

The quantities obtained from cubic, hexagonal, etc., LATTICE SUMS, evaluated at $s=1$, are called Madelung constants. For cubic LATTICE SUMS, they are expressible in closed form for EVEN indices,

$$b_2(2) = -4\beta(1)\eta(1) = -4\,\frac{\pi}{4}\ln 2 = -\pi \ln 2 \quad (1)$$

$$b_4(2) = -8\eta(1)\eta(0) = -8\ln 2 \cdot \tfrac{1}{2} = -4\ln 2, \quad (2)$$

where $\beta(n)$ is the DIRICHLET BETA FUNCTION and $\eta(n)$ is the DIRICHLET ETA FUNCTION. $b_3(1)$ is given by BENSON'S FORMULA,

$$-b_3(1) = \sum_{i,\,j,\,k=-\infty}^{\infty}{}' \frac{(-1)^{i+j+k+1}}{\sqrt{i^2+j^2+k^2}} = 12\pi \sum_{m,\,n=1,\,3,\,\ldots}^{\infty} \operatorname{sech}^2\left(\tfrac{1}{2}\pi\sqrt{m^2+n^2}\right), \quad (3)$$

where the prime indicates that summation over (0, 0, 0) is excluded. $b_3(1)$ is sometimes called "the" Madelung constant, corresponds to the Madelung constant for a 3-D NaCl crystal, and is numerically equal to $-1.74756\ldots$.

For hexagonal LATTICE SUM, $h_2(2)$ is expressible in closed form as

$$h_2(2) = \pi \ln 3\sqrt{3}. \quad (4)$$

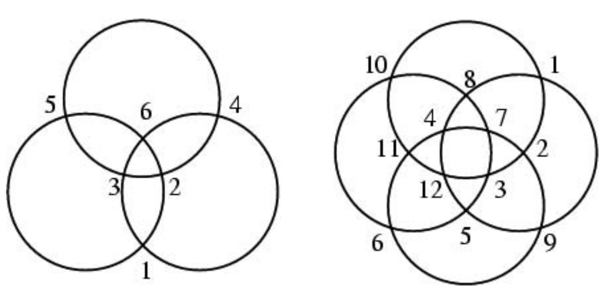
Maeder's Owl Minimal Surface

BOUR'S MINIMAL SURFACE

Maehly's Procedure

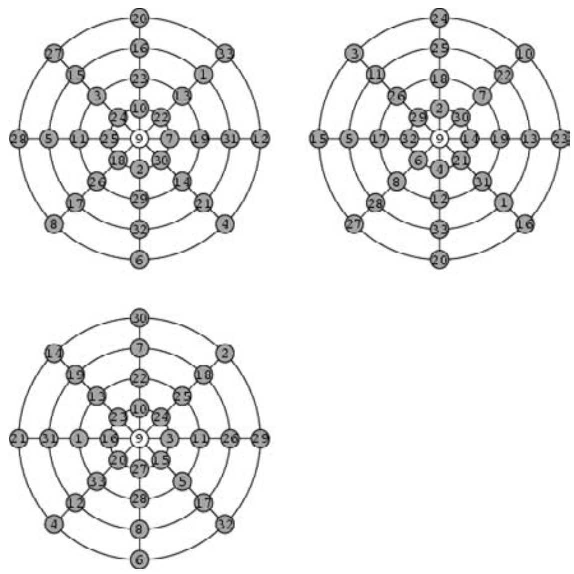
A method for finding ROOTS which defines

$$P_j(x) = \frac{P(x)}{(x - x_1)\cdots(x - x_j)}, \tag{1}$$



so the derivative is

$$P_j'(x) = \frac{P'(x)}{(x - x_1)\cdots(x - x_j)} - \frac{P(x)}{(x - x_1)\cdots(x - x_j)} \sum_{i=1}^{j} (x - x_i)^{-1} \tag{2}$$



One step of NEWTON'S METHOD can then be written as

$$x_{k+1} = x_k - \frac{P(x_k)}{P'(x_k) - P(x_k)\sum_{i=1}^{j}(x_k - x_i)^{-1}}. \tag{3}$$

Magic Circles

A set of n magic circles is a numbering of the intersections of the n CIRCLES such that the sum over all intersections is the same constant for all circles. The above sets of three and four magic circles have magic constants 14 and 39 (Madachy 1979).

Another type of magic circle arranges the number 1, 2, ..., n in a number of rings, which each ring containing the same number of elements and corresponding elements being connected with radial lines. One of the numbers (which is subsequently ignored) is placed at the center. In a magic circle arrangement, the rings have equal sums and this sum is also equal to the sum of elements along each diameter (excluding the central number). Three magic circles using the numbers 1 to 33 are illustrated above. (Hung).

Magic Constant

The number

$$M_2(n) = \frac{1}{n}\sum_{k=1}^{n^2} k = \tfrac{1}{2}n(n^2+1)$$

to which the n numbers in any horizontal, vertical, or *main* diagonal line must sum in a MAGIC SQUARE. The first few values are 1, 5, 15, 34, 65, 111, 175, 260, ... (Sloane's A006003). The magic constant for an nth order magic square starting with an INTEGER A and with entries in an increasing ARITHMETIC SERIES with difference D between terms is

$$M_2(n;\ A,\ D) = \tfrac{1}{2}n\left[2a + D(n^2-1)\right]$$

(Hunter and Madachy 1975, Madachy 1979). In a PANMAGIC SQUARE, in addition to the main diagonals, the broken diagonals also sum to $M_2(n)$.

For a MAGIC CUBE, MAGIC TESSERACT, etc., the magic d-D constant is

$$M_d(n) = \frac{1}{n^{d-1}} \sum_{k=1}^{n^d} k = \tfrac{1}{2} n\left(n^d + 1\right).$$

The first few magic constants are summarized in the following table.

n	$M_2(n)$	$M_3(n)$	$M_4(n)$
Sloane	A006003	A027441	A021003
1	1	1	1
2	5	9	17
3	15	42	123
4	34	130	514
5	65	315	1565

There is a corresponding multiplicative magic constant for MULTIPLICATION MAGIC SQUARES.

A similar magic constant $M_n^{(j)}$ of degree k is defined for MAGIC SERIES and MULTIMAGIC SERIES as $1/n$ times the sum of the first n^2 kth powers,

$$M_n^{(k)} = \frac{1}{n} \sum_{i=1}^{n^2} i^k = \frac{H_{n^2}^{(-p)}}{n},$$

where $H_n^{(k)}$ is a HARMONIC NUMBER of order k. The following table gives the first few values.

n	$k=1$	$k=2$	$k=3$	$k=4$
Sloane	A006003	A052459	A052460	A052461
1	1	1	1	1
2	5	15	50	177
3	15	95	675	5111
4	34	374	4624	60962
5	65	1105	21125	430729

Magic Cube

An $n \times n \times n$ 3-D version of the MAGIC SQUARE in which the n^2 rows, n^2 columns, n^2 pillars (or "files"), and four space diagonals each sum to a single number $M_3(n)$ known as the MAGIC CONSTANT. If the CROSS SECTION diagonals also sum to $M_3(n)$, the magic cube is called a PERFECT MAGIC CUBE; if they do not, the cube is called a SEMIPERFECT MAGIC CUBE, or sometimes an ANDREWS CUBE (Gardner 1988). A pandiagonal cube is a perfect or SEMIPERFECT MAGIC CUBE which is magic not only along the main space diagonals, but also on the broken space diagonals.

A magic cube using the numbers 1, 2, ..., n^3, if it exists, has MAGIC CONSTANT

$$M_3(n) = \tfrac{1}{2} n\left(n^3 + 1\right).$$

For $n = 1$, 2, ..., the magic constants are 1, 9, 42, 130, 315, 651, ... (Sloane's A027441).

4	12	26
11	25	6
27	5	10

20	7	15
9	14	19
13	21	8

18	23	1
22	3	17
2	16	24

60	37	12	21
13	20	61	36
56	41	8	25
1	32	49	48

7	26	55	42
50	47	2	31
11	22	59	38
62	35	14	19

57	40	9	24
16	17	64	33
53	44	5	28
4	29	52	45

6	27	54	43
51	46	3	30
10	23	58	39
63	34	15	18

The above SEMIPERFECT MAGIC CUBES of orders three (Hunter and Madachy 1975, p. 31; Ball and Coxeter 1987, p. 218) and four (Ball and Coxeter 1987, p. 220) have magic constants 42 and 130, respectively. There is a trivial SEMIPERFECT MAGIC CUBE of order one, but no semiperfect cubes of orders two or three exist. Semiperfect cubes of ODD order with $n \geq 5$ and DOUBLY EVEN order can be constructed by extending the methods used for MAGIC SQUARES.

Semiperfect pandiagonal cubes exist for all orders $8n$ and all ODD $n > 8$ (Ball and Coxeter 1987). A perfect pandiagonal magic cube has been constructed by Planck (1950), cited in Gardner (1988).

Magic Geometric Constants

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Let E be a compact connected subset of d-dimensional EUCLIDEAN SPACE. Gross (1964) and Stadje (1981) proved that there is a unique REAL NUMBER $a(E)$ such that for all $x_1, x_2, ..., x_n \in E$, there exists $y \in E$ with

$$\frac{1}{n}\sum_{j=1}^{n}\sqrt{\sum_{k=1}^{d}(x_{j,\,k}-y_k)^2}=a(E). \quad (1)$$

The magic constant $m(E)$ of E is defined by

$$m(E)=\frac{a(E)}{\operatorname{diam}(E)}, \quad (2)$$

where

$$\operatorname{diam}(E)\equiv\max_{u,\,v\in E}\sqrt{\sum_{k=1}^{d}(u_k-v_k)^2}. \quad (3)$$

These numbers are also called DISPERSION NUMBERS and RENDEZVOUS VALUES. For any E, Gross (1964) and Stadje (1981) proved that

$$\tfrac{1}{2}\le m(E)<1. \quad (4)$$

If I is a subinterval of the LINE and D is a circular DISK in the PLANE, then

$$m(I)=m(D)=\tfrac{1}{2}. \quad (5)$$

If C is a CIRCLE, then

$$m(C)=\frac{2}{\pi}=0.6366\ldots \quad (6)$$

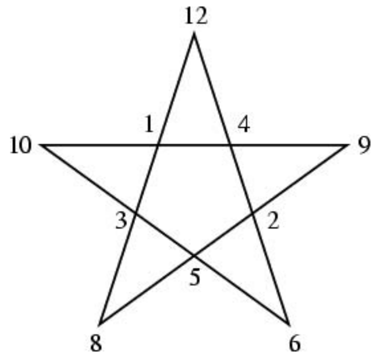
An expression for the magic constant of an ELLIPSE in terms of its SEMIMAJOR and SEMIMINOR AXES lengths is not known. Nikolas and Yost (1988) showed that for a REULEAUX TRIANGLE T

$$0.6675276\le m(T)\le 0.6675284. \quad (7)$$

Denote the MAXIMUM value of $m(E)$ in n-D space by $M(n)$. Then

$M(1)$	$\tfrac{1}{2}$
$M(2)$	$m(T)\le M(2)\le\dfrac{2+\sqrt{3}}{3\sqrt{3}}<0.7182336$
$M(d)$	$\dfrac{d}{d+1}\le M(d)\le\dfrac{[\Gamma(\tfrac{1}{2}d)]^2 2^{d-2}\sqrt{2d}}{\Gamma(d-\tfrac{1}{2})\sqrt{(d+1)\pi}}<\sqrt{\dfrac{d}{d+1}}$

where $\Gamma(z)$ is the GAMMA FUNCTION (Nikolas and Yost 1988).



An unrelated quantity characteristic of a given MAGIC SQUARE is also known as a MAGIC CONSTANT.

Magic Graph

An edge-magic graph is a LABELED GRAPH with e EDGES labeled with distinct elements $\{1,\ 2,\ \ldots,\ e\}$ so that the sum of the EDGE labels at each VERTEX is the same.

A vertex-magic graph labeled VERTICES which give the same sum along every straight line segment. No magic pentagrams can be formed with the number 1, 2, ..., 10 (Trigg 1960; Langman 1962, pp. 80–3; Dongre 1971; Richards 1975; Buckley and Rubin 1977–8; Trigg 1998), but 168 almost magic pentagrams (in which the sums are the same for four of the five lines) can. The figure above show a magic pentagram with sums 24 built using the labels 1, 2, 3, 4, 5, 6, 8, 9, 10, and 12 (Madachy 1979).

Magic Hexagon

An arrangement of close-packed HEXAGONS containing the numbers 1, 2, ..., $H_n = 3n(n-1)+1$, where H_n is the nth HEX NUMBER, such that the numbers along each straight line add up to the same sum. In the above magic hexagon, each line (those of lengths 3, 4, and 5) adds up to 38. This is the only magic hexagon of the counting numbers for any size hexagon, as proved by Trigg (Gardner 1984, p. 24). It was discovered by C. W. Adams, who worked on the problem from 1910 to 1957.

Trigg showed that the magic constant for an order n hexagon would be

$$\frac{9(n^4 - 2n^3 + 2n^2 - n) + 2}{2(2n-1)},$$

which requires $5/(2n-1)$ to be an integer for a solution to exist. But this is an integer for only $n = 1$ (the trivial case of a single hexagon) and Adam's $n = 3$ (Gardner 1984, p. 24).

Magic Labeling

It is conjectured that every TREE with e edges whose nodes are all trivalent or monovalent can be given a "magic" labeling such that the INTEGERS 1, 2, ..., e can be assigned to the edges so that the SUM of the three meeting at a node is constant.

Magic Number

DIGITAL ROOT, MAGIC CONSTANT

Magic Pentagram

MAGIC GRAPH

Magic Series

A set n distinct numbers taken from the interval $[1,\ n^2]$ form a magic series if their sum is the nth MAGIC CONSTANT

$$M_n = \tfrac{1}{2}\,n\left(n^2+1\right)$$

(Kraitchik 1942, p. 143). The numbers of magic series of orders $n = 1, 2, ...$, are 1, 2, 8, 86, 1394, ... (Sloane's A052456). The following table gives the first few magic series of small order.

n	magic series
1	{1}
2	{1, 4}, {2, 3}
3	{1, 5, 9}, {1, 6, 8}, {2, 4, 9}, {2, 5, 8}, {2, 6, 7}, {3, 4, 8}, {3, 5, 7}, {4, 5, 6}

If the sum of the kth powers of these number is the MAGIC CONSTANT of degree k for all $k \in [1,\ p]$, then they are said to form a pth order MULTIMAGIC SERIES. Here, the magic constant $M_n^{(j)}$ of degree k is defined as $1/n$ times the sum of the first n^2 kth powers,

$$M_n^{(k)} = \frac{1}{n}\sum_{i=1}^{n^2} i^k = \frac{H_{n^2}^{(-p)}}{n},$$

where $H_n^{(k)}$ is a HARMONIC NUMBER of order k.

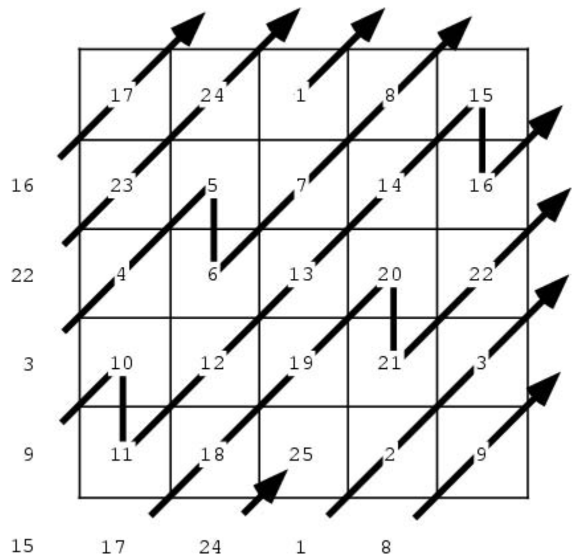
A (normal) magic square consists of the distinct POSITIVE INTEGERS 1, 2, ..., n^2 such that the sum of the n numbers in any horizontal, vertical, or *main* diagonal line is always the same MAGIC CONSTANT

$$M_2(n) = \frac{1}{n}\sum_{k=1}^{n^2} k = \tfrac{1}{2}\,n\left(n^2+1\right).$$

The unique normal square of order three was known to the ancient Chinese, who called it the LO SHU. A version of the order 4 magic square with the numbers 15 and 14 in adjacent middle columns in the bottom row is called DÜRER'S MAGIC SQUARE. Magic squares of order 3 through 8 are shown above.

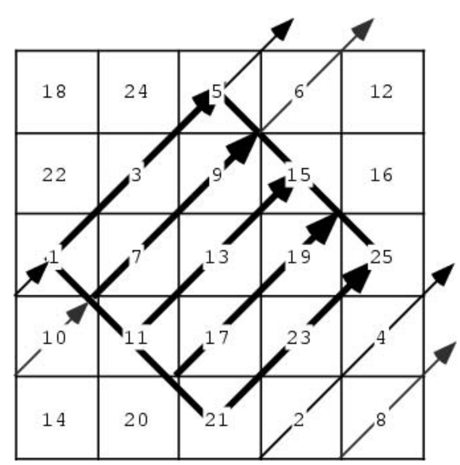


The MAGIC CONSTANT for an nth order magic square starting with an INTEGER A and with entries in an increasing ARITHMETIC SERIES with difference D between terms is

$$M_2(n;\ A,\ D) = \tfrac{1}{2}\,n\left[2a + D\left(n^2-1\right)\right]$$

(Hunter and Madachy 1975). If every number in a magic square is subtracted from n^2+1, another magic square is obtained called the complementary magic square. Squares which are magic under multiplication instead of addition can be constructed and are known as MULTIPLICATION MAGIC SQUARES. In addition, squares which are magic under both addition *and* multiplication can be constructed and are

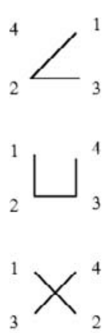
known as ADDITION-MULTIPLICATION MAGIC SQUARES (Hunter and Madachy 1975).



A square that fails to be magic only because one or both of the main diagonal sums do not equal the MAGIC CONSTANT is called a SEMIMAGIC SQUARE. If *all* diagonals (including those obtained by wrapping around) of a magic square sum to the MAGIC CONSTANT, the square is said to be a PANMAGIC SQUARE (also called a DIABOLIC SQUARE or PANDIAGONAL SQUARE). If replacing each number n_i by its square n_i^2 produces another magic square, the square is said to be a BIMAGIC SQUARE (or DOUBLY MAGIC SQUARE). If a square is magic for n_i, n_i^2, and n_i^3, it is called a TREBLY MAGIC SQUARE. If all pairs of numbers symmetrically opposite the center sum to n^2+1, the square is said to be an ASSOCIATIVE MAGIC SQUARE.

Kraitchik (1942) gives general techniques of constructing EVEN and ODD squares of order n. For n ODD, a very straightforward technique known as the Siamese method can be used, as illustrated above (Kraitchik 1942, pp. 148–49). It begins by placing a 1 in any location (in the center square of the top row in the above example), then incrementally placing subsequent numbers in the square one unit above and to the right. The counting is wrapped around, so that falling off the top returns on the bottom and falling off the right returns on the left. When a square is encountered which is already filled, the next number is instead placed *below* the previous one and the method continues as before. The method, also called de la Loubere's method, is purported to have been first reported in the West when de la Loubere returned to France after serving as ambassador to Siam.

A generalization of this method uses an "ordinary vector" (x, y) which gives the offset for each noncolliding move and a "break vector" (u, v) which gives the offset to introduce upon a collision. The standard Siamese method therefore has ordinary vector $(1, -1)$ and break vector (0, 1). In order for this to produce a magic square, each break move must end up on an unfilled cell. Special classes of magic squares can be constructed by considering the absolute sums $|u+v|$, $|(u-x)+(v-y)|$, $|u-v|$, and $|(u-x)-(v-y)| = |u+y-x-v|$. Call the set of these numbers the sumdiffs (sums and differences). If all sumdiffs are RELATIVELY PRIME to n and the square is a magic square, then the square is also a PANMAGIC SQUARE. This theory originated with de la Hire. The following table gives the sumdiffs for particular choices of ordinary and break vectors.



Ordinary Vector	Break Vector	Sumdiffs	Magic Squares	Panmagic Squares
(1, -1)	(0, 1)	(1, 3)	$2k+1$	none
(1, -1)	(0, 2)	(0, 2)	$6k\pm 1$	none
(2, 1)	(1, -2)	(1, 2, 3, 4)	$6k\pm 1$	none
(2, 1)	(1, -1)	(0, 1, 2, 3)	$6k\pm 1$	$6k\pm 1$
(2, 1)	(1, 0)	(0, 1, 2)	$2k+1$	none
(2, 1)	(1, 2)	(0, 1, 2, 3)	$6k\pm 1$	none

A second method for generating magic squares of ODD order has been discussed by J. H. Conway under the name of the "lozenge" method. As illustrated above, in this method, the ODD numbers are built up along diagonal lines in the shape of a DIAMOND in the central part of the square. The EVEN numbers which were missed are then added sequentially along the continuation of the diagonal obtained by wrapping around the square until the wrapped diagonal reaches its initial point. In the above square, the first diagonal therefore fills in 1, 3, 5, 2, 4, the second diagonal fills in 7, 9, 6, 8, 10, and so on.

8	58	59	5	4	62	63	1

An elegant method for constructing magic squares of DOUBLY EVEN order $n = 4m$ is to draw xs through each 4×4 subsquare and fill all squares in sequence. Then replace each entry a_{ij} on a crossed-off diagonal by $(n^2 + 1) - a_{ij}$ or, equivalently, reverse the order of the crossed-out entries. Thus in the above example for $n = 8$, the crossed-out numbers are originally 1, 4, ..., 61, 64, so entry 1 is replaced with 64, 4 with 61, etc.

43	42	71	70	99	98	7	6	35	34

A very elegant method for constructing magic squares of SINGLY EVEN order $n = 4m + 2$ with $m \geq 1$ (there is no magic square of order 2) is due to J. H. Conway, who calls it the "LUX" method. Create an array consisting of $m + 1$ rows of Ls, 1 row of Us, and $m - 1$ rows of Xs, all of length $n/2 = 2m + 1$. Interchange the middle U with the L above it. Now generate the magic square of order $2m + 1$ using the Siamese method centered on the array of letters (starting in the center square of the top row), but fill each set of four squares surrounding a letter sequentially according to the order prescribed by the letter. That order is illustrated on the left side of the above figure, and the completed square is illustrated to the right. The "shapes" of the letters L, U, and X naturally suggest the filling order, hence the name of the algorithm.

It is an unsolved problem to determine the number of magic squares of an arbitrary order, but the number of distinct magic squares (excluding those obtained by rotation and reflection) of order $n = 1, 2, \ldots$ are 1, 0, 1, 880, 275305224, ... (Sloane's A006052; Madachy 1979, p. 87). The 880 squares of order four were enumerated by Frenicle de Bessy in the seventeenth century, and are illustrated in Berlekamp *et al.* (1982, pp. 778–83). The number of 6×6 squares is not known, but Pinn and Wieczerkowski (1998) estimated it to be $(1.7745 \pm 0.0016) \times 10^{19}$ using Monte Carlo simulation and methods from statistical mechanics.

The above magic squares consist only of PRIMES and were discovered by E. Dudeney (1970) and A. W. Johnson, Jr. (Gardner 1984, p. 86; Dewdney 1988). Madachy (1979, pp. 93–6) and Rivera discuss other magic squares composed of PRIMES.

Benjamin Franklin constructed the above 8×8 PANMAGIC SQUARE having MAGIC CONSTANT 260. Any half-row or half-column in this square totals 130, and the four corners plus the middle total 260. In addition, bent diagonals (such as 52–5–4–0–7–3–6) also total 260 (Madachy 1979, p. 87).

In addition to other special types of magic squares, a 3×3 square whose entries are consecutive PRIMES,

illustrated above, has been discovered by H. Nelson (Rivera).

According to a 1913 proof of J. N. Murray (cited in Gardner 1984, pp. 86–7), the smallest magic square composed of consecutive primes *starting with 3 and including the number 1* is of order 12.

Variations on magic squares can also be constructed using letters (either in defining the square or as entries in it), such as the ALPHAMAGIC SQUARE and TEMPLAR MAGIC SQUARE.

Various numerological properties have also been associated with magic squares. Pivari associates the squares illustrated above with Saturn, Jupiter, Mars, the Sun, Venus, Mercury, and the Moon, respectively. Attractive patterns are obtained by connecting consecutive numbers in each of the squares (with the exception of the Sun magic square).

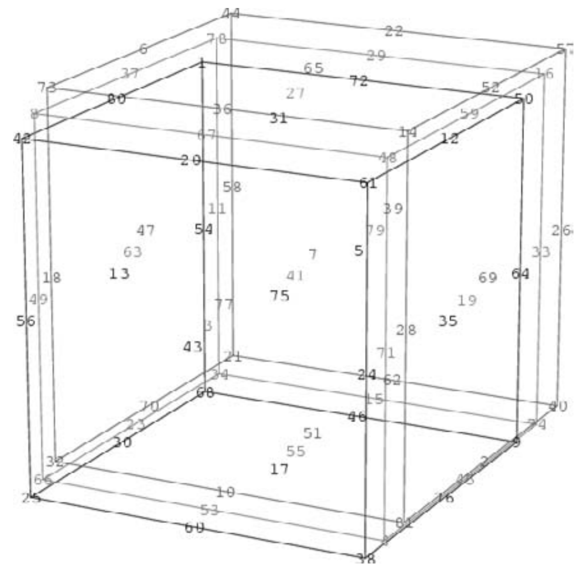
Magic Star



MAGIC GRAPH

Magic Tesseract

A magic tesseract is a 4-D generalization of the 2-D MAGIC SQUARE and the 3-D MAGIC CUBE. A magic tesseract has MAGIC CONSTANT

$$M_4(n) = \frac{1}{2} n(n^4 + 1),$$

so for $n = 1, 2, \ldots$, the magic tesseract constants are 1, 17, 123, 514, 1565, 3891, ... (Sloane's A021003).

Berlekamp *et al.* (1982, p. 783) give a magic TESSERACT. J. Hendricks has constructed magic tesseracts of orders three, four, five (Hendricks 1999a, pp. 128–29), and six (Heinz). M. Houlton has used Hendricks' techniques to construct magic tesseracts of orders 5, 7, and 9.

There are 58 distinct magic tesseracts of order three, modulo rotations and reflections (Heinz, Hendricks 1999), one of which is illustrated above. Each of the 27 rows (e.g., 1–2–0), columns (e.g., 1–0–2), pillars (e.g., 1–4–8), and files (e.g., 1–8–4) sum to the magic constant 123.

Hendricks (1968) has constructed a pan-4-agonal magic tesseract of order 4. No pan-4-agonal magic tesseract of order five is known, and Andrews (1960) and Schroeppel (1972) state that no such tesseract can exist.

The smallest perfect magic tesseract is of order 16, having MAGIC CONSTANT 524,296, and has been constructed by Hendricks (Peterson 1999).

n-dimensional magic hypercubes of order 3 are known for $n = 5$, 6, 7, and 8 (Hendricks). Hendricks has also constructed a perfect 16th order magic tesseract (where perfect means that all hyperplanes are perfect).

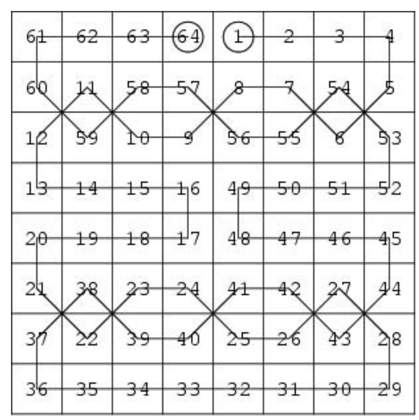
Magic Tour

Let a chess piece make a TOUR on an $n \times n$ CHESSBOARD whose squares are numbered from 1 to n^2 along the path of the chess piece. Then the TOUR is called a magic tour if the resulting arrangement of numbers is a MAGIC SQUARE. If the first and last squares traversed are connected by a move, the tour is said to be closed (or "re-entrant"); otherwise it is open. The MAGIC CONSTANT for the 8×8 CHESSBOARD is 260.



Magic KNIGHT'S TOURS are not possible on $n \times n$ boards for n ODD, and are believed to be impossible for $n = 8$. The "most magic" knight tour known on the 8×8 board is the SEMIMAGIC SQUARE illustrated in the above left figure (Ball and Coxeter 1987, p. 185) having main diagonal sums of 348 and 168. Combining two half-knights' tours one above the other as in the above right figure does, however, give a MAGIC SQUARE (Ball and Coxeter 1987, p. 185).

The above illustration shows a 16×16 closed magic KNIGHT'S TOUR (Madachy 1979).

A magic tour for king moves is illustrated above (Coxeter 1987, p. 186).

Magog Triangle

A NUMBER TRIANGLE of order n with entries 1 to n such that entries are nondecreasing across rows and down columns and all entries in column j are less than or equal to j. An example is

$$\begin{array}{lllll} 1 \\ 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 & 3 \\ 1 & 1 & 2 & 4 & 5. \end{array}$$

Magog triangles are in 1-to-1 correspondence with CYCLICALLY SYMMETRIC PLANE PARTITIONS.

See also CYCLICALLY SYMMETRIC PLANE PARTITION, MONOTONE TRIANGLE

Mahler-Lech Theorem

Let K be a FIELD of CHARACTERISTIC 0 (e.g., the rationals $\mathbb{Q}$) and let $\{u_n\}$ be a SEQUENCE of elements of K which satisfies a difference equation OF THE FORM

$$0 = c_0 u_n + c_1 u_{n+1} + \ldots + c_k u_{n+k},$$

where the COEFFICIENTS c_i are fixed elements of K. Then, for any $c \in K$, we have *either* $u_n = c$ for only finitely many values of n, *or* $u_n = c$ for the values of n in some ARITHMETIC PROGRESSION.

The proof involves embedding certain FIELDS inside the P-ADIC NUMBERS $\mathbb{Q}_p$ for some PRIME p, and using properties of zeros of POWER SERIES over $\mathbb{Q}_p$ (STRASSMAN'S THEOREM).

See also ARITHMETIC PROGRESSION, P-ADIC NUMBER, STRASSMAN'S THEOREM

Mahler Measure

This entry contributed by KEVIN O'BRYANT

For a polynomial $P(x_1, x_2, \ldots, x_k)$, the Mahler measure of P is defined by

$$M_k(P) \equiv \exp\left[\int_0^1 \cdots \int_0^1 \ln\left|P\left(e^{2\pi i t_1}, \ldots, e^{2\pi i t_k}\right)\right| dt_1 \cdots dt_k\right]. \quad (1)$$

Using JENSEN'S FORMULA, it can be shown that for $P(x) = a\prod_{i=1}^n (x - \alpha_i)$,

$$M_1(P) = |a| \prod_{i=1}^n \max\{1, |\alpha_i|\} \quad (2)$$

(Borwein and Erdélyi 1995, p. 271).

Specific cases are given by

$$M_1(ax+b) = \max\{|a|, |b|\} \quad (3)$$

$$M_2(1+x+y) = M_1(\max\{1, |1+x|\}) \quad (4)$$

$$M_2(1+x+y-xy) = M_1(\max\{|1-x|, |1+x|\}) \quad (5)$$

(Borwein and Erdélyi 1995, p. 272).

A product of CYCLOTOMIC POLYNOMIALS has Mahler measure 1. LEHMER'S MAHLER MEASURE PROBLEM conjectures that a particular univariate polynomial has the smallest possible Mahler measure other than 1.

The Mahler measure for a univariate polynomial can be computed in *Mathematica* as follows.

```
MahlerMeasure[p_, x_] := Module[
    {roots = x /. {ToRules[Roots[p == 0,
x]]}},
   Abs[Function[x, p][0]] Times @@
    (Max[Abs[#], 1] & /@ roots)
  ]
```

SEMIMAJOR AXIS

Majorization

This entry contributed by SERGE BELONGIE

Let $x = (x_1, x_2, \ldots, x_n)$ and $y = (y_1, y_2, \ldots, y_n)$ be nonincreasing sequences of real numbers. Then x majorizes y if, for each $k = 1, 2, \ldots, n$,

$$\sum_{i=1}^{k} x_i \geq \sum_{i=1}^{k} y_i,$$

with equality if $k = n$. Note that some caution is needed when consulting the literature, since the direction of the inequality is not consistent from reference to reference. An order-free characterization along the lines of HORN'S THEOREM is also readily available.

If P is a doubly stochastic matrix, then $y = \mathsf{P}x$ iff y is majorized by x. Intuitively, if x majorizes y, then y is more "mixed" than x. HORN'S THEOREM relates the eigenvalues of a HERMITIAN MATRIX A to its diagonal entries using majorization. Given two vectors λ, $\mathbf{v} \in \mathbb{R}^n$, then λ majorizes $\mathbf{v}$ iff there exists a HERMITIAN MATRIX A with eigenvalues λ_i and diagonal entries v_i.

Makeham Curve

The function defined by

$$y \equiv k s^x b^{q^x}$$

which is used in actuarial science for specifying a simplified mortality law (Kenney and Keeping 1962, pp. 241–42). Using $s(x)$ as the probability that a newborn will achieve age x, the Makeham law (1860) uses

$$s(x) = \exp(-Ax - B(c^x - 1))$$

for $B > 0$, $A \geq -B$, $c > 1$, $x \geq 0$.

Malfatti Circles

Three circles packed inside a RIGHT TRIANGLE which are each tangent to the other two and to two sides of the TRIANGLE. Although these circles were for many years thought to provide the solutions to MALFATTI'S RIGHT TRIANGLE PROBLEM, they were subsequently shown *never* to provide the solution.

See also APOLLONIAN GASKET, MALFATTI'S RIGHT TRIANGLE PROBLEM, SODDY CIRCLES

Malfatti Points

AJIMA-MALFATTI POINTS

Malfatti's Right Triangle Problem

In 1803, Malfatti asked for the three columns (of possibly different sizes) which, when carved out of a right triangular prism, would have the largest possible total CROSS SECTION. This is equivalent to finding the maximum total AREA of three CIRCLES which can be packed inside a RIGHT TRIANGLE of any shape without overlapping. Malfatti gave the solution as three CIRCLES (the MALFATTI CIRCLES) tangent to each other and to two sides of the TRIANGLE. In 1930, it was shown that the MALFATTI CIRCLES were not always the best solution. Then Goldberg (1967) showed that, even worse, they are *never* the best solution. Wells (1991) illustrates specific cases where alternative solutions are clearly optimal.

Mandelbar Set

A FRACTAL set analogous to the MANDELBROT SET or its generalization to a higher power with the variable z replaced by its COMPLEX CONJUGATE $\bar{z}$.

See also MANDELBROT SET

Mandelbrot Set

The set obtained by the QUADRATIC RECURRENCE

$$z_{n+1} = z_n^2 + C, \tag{1}$$

where points C for which the orbit $z_0 = 0$ does not tend to infinity are in the SET. It marks the set of points in the COMPLEX PLANE such that the corresponding JULIA SET is CONNECTED and not COMPUTABLE. The Mandelbrot set was originally called a MU MOLECULE by Mandelbrot.

J. Hubbard and A. Douady proved that the Mandelbrot set is CONNECTED. Shishikura (1994) proved that the boundary of the Mandelbrot set is a FRACTAL with HAUSDORFF DIMENSION 2. However, it is not yet known if the Mandelbrot set is pathwise-connected. If it is pathwise-connected, then Hubbard and Douady's proof implies that the Mandelbrot set is the image of a CIRCLE and can be constructed from a DISK by collapsing certain arcs in the interior (Douady 1986).

The AREA of the set is known to lie between 1.5031 and 1.5702; it is estimated as 1.50659....

Decomposing the COMPLEX coordinate $z = x + iy$ and $z_0 = a + ib$ gives

$$x' = x^2 - y^2 + a \tag{2}$$

$$y' = 2xy + b. \tag{3}$$

In practice, the limit is approximated by

$$\lim_{n\to\infty} |z_n| \approx \lim_{n\to n_{\max}} |z_n| < r_{\max}. \tag{4}$$

Beautiful computer-generated plots can be created by coloring nonmember points depending on how quickly they diverge to $r_{\max}$. A common choice is to define an INTEGER called the COUNT to be the largest n such that $|z_n| < r$, where r is usually taken as $r = 2$, and to color points of different COUNT different colors. The boundary between successive COUNTS defines a series of "LEMNISCATES," called EQUIPOTENTIAL CURVES by Peitgen and Saupe (1988), $|L_n(C)| = r$ which have distinctive shapes. The first few LEMNISCATES are

$$L_1(C) = C \tag{5}$$

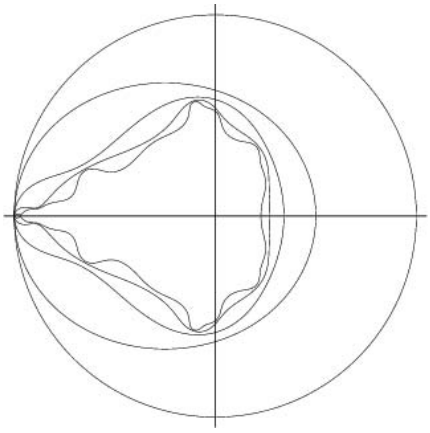
$$L_2(C) = C(C+1) \tag{6}$$

$$L_3(C) = C + \left(C + C^2\right)^2 \tag{7}$$

$$L_4(C) = C + \left[\left(C + C^2\right)^2\right]^2. \tag{8}$$

When written in CARTESIAN COORDINATES, the first three of these are

$$r^2 = x^2 + y^2 \tag{9}$$



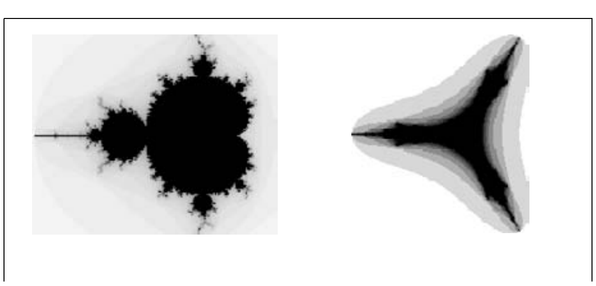
$$r^2 = \left(x^2 + y^2\right)\left[(x+1)^2 + y^2\right] \tag{10}$$

$$\begin{aligned} r^2 = {} & \left(x^2 + y^2\right)\left(1 + 2x + 5x^2 + 6x^3 + 6x^4 + 4x^5 + x^6\right. \\ & -3y^2 - 2xy^2 + 8x^2y^2 + 8x^3y^2 + 3x^4y^2 + 2y^4 + 4xy^4 \\ & \left.+3x^2y^4 + y^6\right) \end{aligned} \tag{11}$$

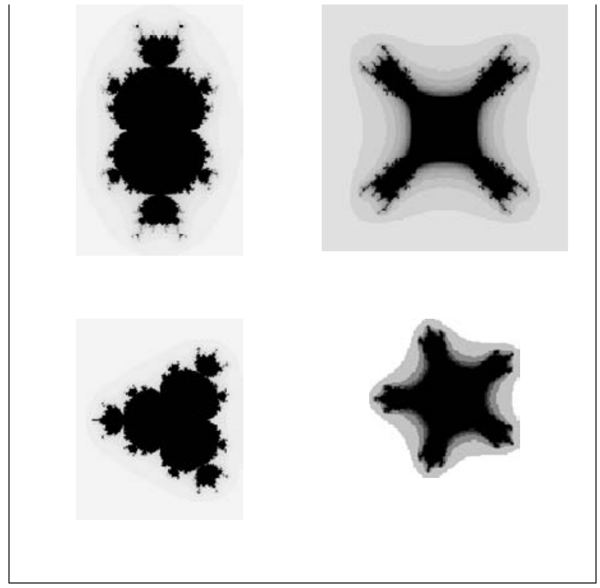
which are a CIRCLE, an OVAL, and a PEAR CURVE. In fact, the second LEMNISCATE L_2 can be written in terms of a new coordinate system with $x' \equiv x - 1/2$ as

$$\left[\left(x' - \tfrac{1}{2}\right)^2 + y^2\right]\left(\left(x' + \tfrac{1}{2}\right)^2 + y^2\right) = r^2, \qquad (12)$$

which is just a CASSINI OVAL with $a = 1/2$ and $b^2 = r$. The LEMNISCATES grow increasingly convoluted with higher COUNT and approach the Mandelbrot set as the COUNT tends to infinity.



The kidney bean-shaped portion of the Mandelbrot set is bordered by a CARDIOID with equations



$$4x = 2\cos t - \cos(2t) \qquad (13)$$

$$4y = 2\sin t - \sin(2t). \qquad (14)$$

The adjoining portion is a CIRCLE with center at $(-1, 0)$ and RADIUS $1/4$. One region of the Mandelbrot set containing spiral shapes is known as SEA HORSE VALLEY because the shape resembles the tail of a sea horse.

Generalizations of the Mandelbrot set can be constructed by replacing z_n^2 with z_n^k or $(\bar{z}_n)^k$, where k is a POSITIVE INTEGER and $\bar{z}$ denotes the COMPLEX CONJUGATE of z. The following figures show the FRACTALS obtained for $k = 2$, 3, and 4 (Dickau). The plots on the right have z replaced with $\bar{z}$ and are sometimes called "MANDELBAR SETS."

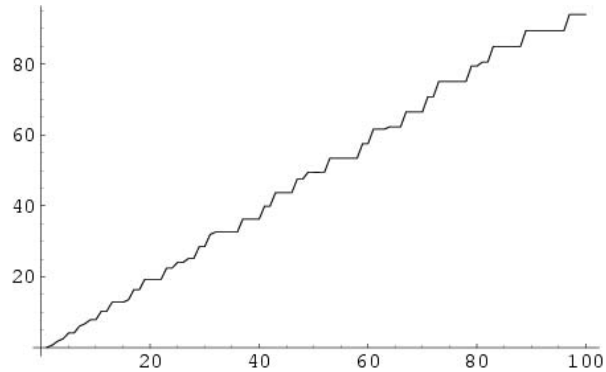
Mangoldt Function



The function defined by

$$\Lambda(n) \equiv \begin{cases} \ln p & \text{if } n = p^k \text{ for } p \text{ a prime} \\ 0 & \text{otherwise,} \end{cases} \tag{1}$$

sometimes also called the lambda function. $\exp(\Lambda(n))$ is also given by $[1, 2, \ldots, n]/[1, 2, \ldots, n-1]$, where $[a, b, c, \ldots]$ denotes the LEAST COMMON MULTIPLE. The first few values of $\exp((n))$ for $n = 1, 2, \ldots$, plotted above, are 1, 2, 3, 2, 5, 1, 7, 2, ... (Sloane's A014963). The Mangoldt function is related to the RIEMANN ZETA FUNCTION $\zeta(z)$ by

$$-\frac{\zeta'(s)}{\zeta(s)} = \sum_{n=1}^{\infty} \frac{\Lambda(n)}{n^s}, \tag{2}$$

where $\Re[s] > 1$ (Hardy 1999, p. 28; Krantz 1999, p. 161).

The SUMMATORY Mangoldt function, illustrated above, is defined by

$$\psi(x) \equiv \sum_{n \leq x} \Lambda(n), \tag{3}$$

where $\Lambda(n)$ is the MANGOLDT FUNCTION, and is also known as the second CHEBYSHEV FUNCTION. $\psi(x)$ has the explicit formula

$$\psi(x) = x - \sum_{\rho} \frac{x^\rho}{\rho} - \ln(2\pi) - \tfrac{1}{2}\ln(1 - x^2), \tag{4}$$

where the second SUM is over all complex zeros ρ of the RIEMANN ZETA FUNCTION $\zeta(s)$, i.e., those in the CRITICAL STRIP so $0 < \Re[\rho] < 1$, and interpreted as

$$\lim_{t \to \infty} \sum_{|\Im(\rho)| < t} \frac{x^\rho}{\rho}. \tag{5}$$

Vardi (1991, p. 155) also gives the interesting formula

$$\ln([x]!) = \psi(x) + \psi\left(\tfrac{1}{2}x\right) + \psi\left(\tfrac{1}{3}x\right) + \ldots, \tag{6}$$

where $[x]$ is the NINT function and $n!$ is a FACTORIAL. Vallée Poussin's version of the PRIME NUMBER THEOREM states that

$$\psi(x) = x + \mathcal{O}\left(xe^{-a\sqrt{\ln x}}\right) \tag{7}$$

for some a (Davenport 1980, Vardi 1991). The PRIME NUMBER THEOREM is equivalent to the statement that

$$\psi(x) = x + o(x) \tag{8}$$

as $x \to \infty$ (Dusart 1999). The RIEMANN HYPOTHESIS is equivalent to

$$\psi(x) = x + \mathcal{O}\left(\sqrt{x}(\ln x)^2\right) \tag{9}$$

(Davenport 1980, p. 114; Vardi 1991).

Manifold

A manifold is a TOPOLOGICAL SPACE which is LOCALLY EUCLIDEAN (i.e., around every point, there is a NEIGHBORHOOD which is topologically the same as the OPEN UNIT BALL in $\mathbb{R}^n$). To illustrate this idea, consider the ancient belief that the Earth was flat as contrasted with the modern evidence that it is round. This discrepancy arises essentially from the fact that on the small scales that we see, the Earth does indeed look flat (although the Greeks did notice that the last part of a ship to disappear over the horizon was the mast). In general, any object which is nearly "flat" on small scales is a manifold, and so manifolds constitute a generalization of objects we could live on in which we would encounter the round/flat Earth problem, as first codified by Poincaré. More formally, any object that can be "charted" is a manifold.

a torus *another torus*

As a TOPOLOGICAL SPACE, a manifold can be COMPACT or not compact, and CONNECTED or disconnected. Typically, by "manifold," one means a manifold without boundary. However, an author will sometimes be more precise and use the term OPEN MANIFOLD (for a noncompact manifold without boundary) or CLOSED MANIFOLD (for a COMPACT MANIFOLD without boundary).

If a manifold contains its own boundary, it is called, not surprisingly, a "MANIFOLD WITH BOUNDARY." The closed unit ball in $\mathbb{R}^n$ is a manifold with boundary, and its boundary is the unit sphere. The concept can be generalized to manifolds with corners. By definition, every point on a manifold has a neighborhood together with a HOMEOMORPHISM of that neighborhood with an OPEN BALL in $\mathbb{R}^n$. In addition, a manifold must have a SECOND COUNTABLE TOPOLOGY. Unless otherwise indicated, a manifold is assumed to have finite DIMENSION n, for n a positive integer.

DIFFERENTIABLE MANIFOLDS are manifolds for which overlapping charts "relate smoothly" to each other, meaning that the inverse of one followed by the other is an infinitely differentiable map from EUCLIDEAN SPACE to itself. Manifolds arise naturally in a variety of mathematical and physical applications as "global objects." For example, in order to precisely describe all the configurations of a robot arm or all the possible positions and momenta of a rocket, an object is needed to store all of these parameters. The objects that crop up are manifolds. From the geometric perspective, manifolds represent the profound idea having to do with global versus local properties.

The basic example of a manifold is EUCLIDEAN SPACE, and many of its properties carry over to manifolds. In addition, any smooth boundary of a subset of Euclidean space, like the circle or the sphere, is a manifold. Manifolds are therefore of interest in the study of GEOMETRY, TOPOLOGY, and ANALYSIS.

One of the goals of topology is to find ways of distinguishing manifolds. For instance, a circle is topologically the same as any closed loop, no matter how different these two manifolds may appear. Similarly, the surface of a coffee mug with a handle is topologically the same as the surface of the donut, and this type of surface is called a (one-handled) TORUS.

A SUBMANIFOLD is a subset of a manifold which is itself a manifold, but has smaller dimension. For example, the equator of a sphere is a submanifold. Many common examples of manifolds are submani-

folds of Euclidean space. In fact, Whitney showed in the 1930s that any manifold can be EMBEDDED in $\mathbb{R}^N$, where $N = 2n + 1$.

A manifold may be endowed with more structure than a locally Euclidean topology. For example, it could be SMOOTH, COMPLEX, or even ALGEBRAIC (in order of specificity). A smooth manifold with a METRIC is called a RIEMANNIAN MANIFOLD, and one with a SYMPLECTIC STRUCTURE is called a SYMPLECTIC MANIFOLD. Finally, a COMPLEX MANIFOLD with a KÄHLER STRUCTURE is called a KÄHLER MANIFOLD.

Mann's Theorem

This entry contributed by KEVIN O'BRYANT

A theorem widely circulated as the "α-β conjecture" and proved by Mann (1942). It states that if A and B are sets of integers each containing 0, then

$$\sigma(A \oplus B) \geq \min\{1,\ \sigma(A) + \sigma(B)\}.$$

Here, $A \oplus B$ denotes the DIRECT SUM, i.e., $A \oplus B = \{a + b : a \in A,\ b \in B\}$, and σ is the SCHNIRELMANN DENSITY.

Mann's theorem is best possible in the sense that $A = B = \{0,\ 1,\ 11,\ 12,\ 13,\ \ldots\}$ satisfies $\sigma(A \oplus B) = \sigma(A) + \sigma(B)$.

Mann's theorem implies SCHNIRELMANN'S THEOREM as follows. Let $P = \{0,\ 1\} \cup \{p : p \text{ prime}\}$, then Mann's theorem proves that $\sigma(P + P + P + P) > 2\sigma(P + P)$, so as more and more copies of the primes are included, the SCHNIRELMANN DENSITY increases at least linearly, and so reaches 1 with at most $2 \cdot 1/(\sigma(P + P))$ copies of the primes. Since the only sets with SCHNIRELMANN DENSITY 1 are the sets containing all positive integers, SCHNIRELMANN'S THEOREM follows.

MANOVA

MANOVA ("multiple analysis of variance") is a procedure for testing the equality of mean vectors of more than two populations. The technique is analogous to ANOVA for univariate data, except that groups are compared on multiple response variables simultaneously. While F-tests can be used in the uniseriate case to assess the hypothesis under consideration, there is no single test statistic in the multivariate case that is optimal in all situations (Everitt and Wykes 1999, p. 125).

Mantissa

For a REAL NUMBER x, the mantissa is defined as the POSITIVE FRACTIONAL PART $x - \lfloor x \rfloor = \text{frac(x)}$, where $\lfloor x \rfloor$ denotes the FLOOR FUNCTION.

See also CHARACTERISTIC (REAL NUMBER), FLOOR FUNCTION, SCIENTIFIC NOTATION

Many-to-One

A FUNCTION f which may (but does not necessarily) associate a given member of the RANGE of f with more than one member of the DOMAIN of f. For example, TRIGONOMETRIC FUNCTIONS such as $\sin x$ are many-to-one since $\sin x = \sin(2\pi + x) = \sin(4\pi + x) = \cdots$.

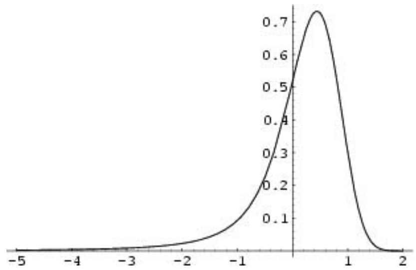
Map

A way of associating unique objects to every point in a given SET. So a map from $A \mapsto B$ is an object f such that for every $A \in B$, there is a unique object $f(a) \in B$. The terms FUNCTION and MAPPING are synonymous with map.

the following table gives several common types of complex maps.



Mapping	FORMULA	Domain
Inversion	$f(z) = \frac{1}{z}$	
Magnification	$f(z) = az$	$a \in \mathbb{R} \neq 0$
Magnification + Rotation	$f(z) = az$	$a \in \mathbb{C} \neq 0$
MÖBIUS TRANSFORMATION	$f(z) = \frac{az + b}{cz + d}$	$a, b, c, d \in \mathbb{C}$
ROTATION	$f(z) = e^{i\theta} z$	$\theta \in \mathbb{R}$
TRANSLATION	$f(z) = z + a$	$a \in \mathbb{C}$

Map-Airy Distribution

A probability distribution having density

$$P(x) = 2e^{-2x^3/3}\left[x\,\mathrm{Ai}(x^2) - \mathrm{Ai}'(x^2)\right],$$

where $\mathrm{Ai}(x)$ is the AIRY FUNCTION and $\mathrm{Ai}'(x) = d\mathrm{Ai}(x)/dx$. The corresponding distribution function is

$$\begin{aligned} D(x) = \tfrac{1}{3} - 2x^5\ & \frac{{}_2F_2\left(\frac{7}{6}, \frac{5}{3}, \frac{7}{3}, \frac{8}{3}; -\frac{4}{3}x^3\right)}{15 \cdot 3^{2/3}\Gamma\left(\frac{5}{3}\right)} \\ -x^4\ & \frac{{}_2F_2\left(\frac{5}{6}, \frac{4}{3}, \frac{5}{3}, \frac{7}{3}; -\frac{4}{3}x^3\right)}{6 \cdot 3^{1/3}\left(\frac{4}{3}\right)} \\ +x^2\ & \frac{{}_2F_2\left(\frac{1}{6}, \frac{2}{3}, \frac{1}{3}, \frac{5}{3}; -\frac{4}{3}x^3\right)}{3^{2/3}\Gamma\left(\frac{2}{3}\right)} \\ +2x\ & \frac{{}_2F_2\left(-\frac{1}{6}, \frac{1}{3}; -\frac{1}{3}, \frac{4}{3}; -\frac{4}{3}x^3\right)}{3^{1/3}\Gamma\left(\frac{1}{3}\right)} \end{aligned}$$

(M. Trott). The density is normalized with

$$\int_{-\infty}^{\infty} A(x)\,dx = 1.$$

The MEAN is 0, but the second moment μ_2 is undefined.

Map Coloring

Given a map with GENUS $g > 0$, Heawood showed in 1890 that the maximum number N_u of colors necessary to color a map (the CHROMATIC NUMBER) on an unbounded surface is

$$N_u \equiv \left\lfloor \tfrac{1}{2}\left(7+\sqrt{48g+1}\right)\right\rfloor = \left\lfloor \tfrac{1}{2}\left(7+\sqrt{49-24\chi}\right)\right\rfloor,$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION, g is the GENUS, and χ is the EULER CHARACTERISTIC. This is the HEAWOOD CONJECTURE. In 1968, for any orientable surface other than the SPHERE (or equivalently, the PLANE) and any nonorientable surface other than the KLEIN BOTTLE, N_u was shown to be not merely a maximum, but the actual number needed (Ringel and Youngs 1968).

When the FOUR-COLOR THEOREM was proven, the Heawood FORMULA was shown to hold also for all orientable and nonorientable surfaces with the exception of the KLEIN BOTTLE. For this case, the actual number of colors N needed is six–*one less than* $N_u = 7$ (Franklin 1934; Saaty 1986, p. 45).

surface	g	N_u	N
KLEIN BOTTLE	1	7	6
MÖBIUS STRIP	$\frac{1}{2}$	6	6
PLANE	0	4	4
PROJECTIVE PLANE	$\frac{1}{2}$	6	6
SPHERE	0	4	4
TORUS	1	7	7

Mapes' Method

A method for computing the PRIME COUNTING FUNCTION. Define the function

$$T_k(x,\ a) = (-1)^{\beta_0+\beta_1+\ldots+\beta_{a-1}} \left\lfloor \frac{x}{p_1^{\beta_0} p_2^{\beta_1} \cdots p_a^{\beta_{a-1}}} \right\rfloor, \tag{1}$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION and the β_i are the binary digits (0 or 1) in

$$k = 2^{a-1}\beta_{a-1} + 2^{a-2}\beta_{a-2} + \ldots + 2^1\beta_1 + 2^0\beta_0. \tag{2}$$

The LEGENDRE SUM can then be written

$$\phi(x,\ a) = \sum_{k=0}^{2^a-1} T_k(x,\ a). \tag{3}$$

The first few values of $T_k(x,\ a)$ are

$$T_0(x,\ 3) = \lfloor x \rfloor \tag{4}$$

$$T_1(x,\ 3) = -\left\lfloor \frac{x}{p_1} \right\rfloor \tag{5}$$

$$T_2(x,\ 3) = -\left\lfloor \frac{x}{p_2} \right\rfloor \tag{6}$$

$$T_3(x,\ 3) = \left\lfloor \frac{x}{p_1 p_2} \right\rfloor \tag{7}$$

$$T_4(x,\ 3) = \left\lfloor \frac{x}{p_3} \right\rfloor \tag{8}$$

$$T_5(x,\ 3) = \left\lfloor \frac{x}{p_1 p_3} \right\rfloor \tag{9}$$

$$T_6(x,\ 3) = \left\lfloor \frac{x}{p_2 p_3} \right\rfloor \tag{10}$$

$$T_7(x,\ 3) = -\left\lfloor \frac{x}{p_1 p_2 p_3} \right\rfloor. \tag{11}$$

Mapes' method takes time $\sim x^{0.7}$, which is slightly faster than the LEHMER-SCHUR METHOD.

Map Folding

A general FORMULA giving the number of distinct ways of folding an $N = m \times n$ rectangular map is not known. A distinct folding is defined as a permutation of N numbered cells reading from the top down. Lunnon (1971) gives values up to $n = 28$.

n	$1 \times n$	$2 \times n$	$3 \times n$	$4 \times n$	$5 \times n$
1	1	1			

2	2	8			
3	6	60	1368		
4	16	1980		300608	
5	59	19512			18698669
6	144	15552			

The limiting ratio of the number of $1 \times (n+1)$ strips to the number of $1 \times n$ strips is given by

$$\lim_{n\to\infty} \frac{[1 \times (n+1)]}{[1 \times n]} \in [3.3868,\ 3.9821].$$

Map Projection

A projection which maps a SPHERE (or SPHEROID) onto a PLANE. Map projections are generally classified into groups according to common properties (cylindrical vs. conical, conformal vs. area-preserving, etc.), although such schemes are generally not mutually exclusive. Early compilers of classification schemes include Tissot (1881), Close (1913), and Lee (1944). However, the categories given in Snyder (1987) remain the most commonly used today, and Lee's terms authalic and aphylactic are not commonly encountered.

No projection can be simultaneously CONFORMAL and AREA-PRESERVING.

Marginal Analysis

Let $R(x)$ be the revenue for a production x, $C(x)$ the cost, and $P(x)$ the profit. Then

$$P(x) = R(x) - C(x),$$

and the marginal profit for the x_0th unit is defined by

$$P'(x_0) = R'(x_0) - C'(x_0),$$

where $P'(x)$, $R'(x)$, and $C'(x)$ are the DERIVATIVES of $P(x)$, $R(x)$, and $C(x)$, respectively.

See also DERIVATIVE

Marginal Probability

Let S be partitioned into $r \times s$ disjoint sets E_i and F_j where the general subset is denoted $E_i \cap F_j$. Then the marginal probability of E_i is

$$P(E_i) = \sum_{j=1}^{s} P(E_i \cap F_j).$$

Markov Algorithm

An ALGORITHM which constructs allowed mathematical statements from simple ingredients.

Markov Chain

A collection of random variables $\{X_t\}$ (where the index t runs through 0, 1, ...) having the property that, given the present, the future is conditionally independent of the past. In other words,

$$P(X_t = j | X_0 = i_0,\ X_1 = i_1,\ \ldots X_{t-1} = i_{t-1}) = P(X_t = j | X_{t-1} = i_{t-1}).$$

If a MARKOV SEQUENCE of random variates x_n take the discrete values a_1, ..., a_N, then

$$P\left(x_n = a_{i_n} | x_{n-1} = a_{i_{n-1}},\ \ldots,\ x_1 = a_1\right) = P\left(x_n = a_{i_n} | x_{n-1} = a_{i_{n-1}}\right),$$

and the sequence x_n is called a Markov chain (Papoulis 1984, p. 532).

A SIMPLE RANDOM WALK is an example of a Markov chain.

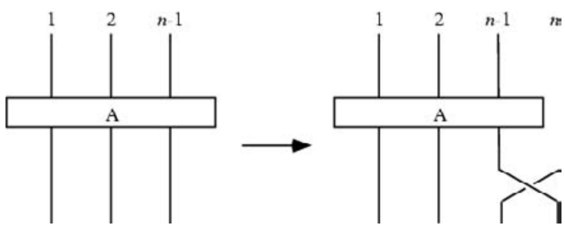
Markov Matrix



STOCHASTIC MATRIX

Markov Moves

A type I move (CONJUGATION) takes $AB \to BA$ for A, $B \in B_n$ where B_n is a BRAID GROUP.

A type II move (STABILIZATION) takes $A \to Ab_n$ or $A \to Ab_n^{-1}$ for $A \in B_n$ and b_n, Ab_n, and $Ab_n^{-1} \in B_{n+1}$.

See also BRAID GROUP, CONJUGATION, KNOT MOVE, REIDEMEISTER MOVES, STABILIZATION

Markov Number

The Markov numbers m are the union of the solutions (x, y, z) to the DIOPHANTINE EQUATION

$$x^2 + y^2 + z^2 = 3xyz,$$

and are related to LAGRANGE NUMBERS L_n by

$$L_n = \sqrt{9 - \frac{4}{n^2}}.$$

The first few solutions are $(x, y, z) = (1, 1, 1)$, $(1, 1, 2)$, $(1, 2, 5)$, $(1, 5, 13)$, $(2, 5, 29)$, ... All solutions can be generated from the first two of these since the equation is a quadratic in each of the variables, so one integer solution leads to a second, and it turns out that all solutions (other than the first two singular ones) have distinct values of x, y, and z, and share two of their three values with three other solutions (Guy 1994, p. 166). The Markov numbers are then given by 1, 2, 5, 13, 29, 34, ... (Sloane's A002559).

The Markov numbers for triples (x, y, z) in which one term is 5 are 1, 2, 13, 29, 194, 433, ... (Sloane's A030452), whose terms are given by the RECURRENCE RELATION

$$a(n) = 15a(n-2) - a(n-4), \qquad (1)$$

with $a(0) = 1$, $a(1) = 2$, $a(2) = 13$, and $a(3) = 29$.

The solutions can be arranged in an infinite tree with two smaller branches on each trunk. It is not known if two different regions can have the same label. Strangely, the regions adjacent to 1 have alternate FIBONACCI NUMBERS 1, 2, 5, 13, 34, ..., and the regions adjacent to 2 have alternate PELL NUMBERS 1, 5, 29, 169, 985, ...

Let $M(N)$ be the number of TRIPLES with $x \le y \le z \le N$, then

$$M(n) = C(\ln N)^2 + \mathcal{O}((\ln N)^{1+\epsilon}),$$

where $C \approx 0.180717105$ (Guy 1994, p. 166).

Markov Process

A random process whose future probabilities are determined by its most recent values. A STOCHASTIC PROCESS $x(t)$ is called Markov if for every n and

$$t_1 < t_2 \ldots < t_n$$

we have

$$P(x(t_n) \le x_n | x(t_{n-1}), \ldots, x(t_1)) = P(x(t_n) \le x_n | x(t_{n-1})).$$

This is equivalent to

$$P(x(t_n) \le x_n | x(t) \text{ for all } t \le t_{n-1}) = P(x(t_n) \le x_n | x(t_{n-1}))$$

(Papoulis 1984, p. 535).

Markov Sequence

A sequence X_1, X_2, ... of random variates is called Markov (or Markoff) if, for any n,

$$F(X_n|X_{n-1}, X_{n-2}, \ldots, X_1) = F(X_n|X_{n-1}),$$

i.e., if the conditional distribution F of X_n assuming X_{n-1}, X_{n-2}, ..., X_1 equals the conditional distribution F of X_n assuming only X_{n-1} (Papoulis 1984, pp. 528–29). The transitional densities of a Markov sequence satisfy the CHAPMAN-KOLMOGOROV EQUATION.

Markov's Inequality

If x takes only NONNEGATIVE values, then

$$P(x \geq a) \leq \frac{\langle x \rangle}{a}.$$

To prove the theorem, write

$$\langle x \rangle = \int_0^\infty xf(x)\,dx = \int_0^a xf(x)\,dx + \int_a^\infty xf(x)\,dx.$$

Since $P(x)$ is a probability density, it must be ≥ 0. We have stipulated that $x \geq 0$, so

$$\begin{aligned}\langle x \rangle &= \int_0^a xf(x)\,dx + \int_a^\infty xf(x)\,dx \\ &\geq \int_0^\infty xf(x)\,dx \geq \int_0^\infty af(x)\,dx \\ &= a\int_0^\infty f(x)\,dx = aP(x \geq a),\end{aligned}$$

Q.E.D.

Markov Spectrum

A SPECTRUM containing the REAL NUMBERS larger than FREIMAN'S CONSTANT.

Markov's Theorem

Published by A. A. Markov in 1935, Markov's theorem states that equivalent BRAIDS expressing the same LINK are mutually related by successive applications of two types of MARKOV MOVES. Markov's theorem is difficult to apply in practice, so it is difficult to establish the equivalence or nonequivalence of LINKS having different BRAID representations.

See also BRAID, LINK, MARKOV MOVES

Marriage Theorem

If a group of men and women may date only if they have previously been introduced, then a complete set of dates is possible IFF every subset of men has collectively been introduced to at least as many women, and vice versa (Hall 1935; Chartrand 1985, p. 121; Skiena 1990, p. 240).

Married Couples Problem

Also called the MÉNAGE PROBLEM. In how many ways can n married couples be seated around a circular table in such a manner than there is always one man between two women and none of the men is next to his own wife? The solution (Ball and Coxeter 1987, p. 50) uses DISCORDANT PERMUTATIONS and can be given in terms of LAISANT'S RECURRENCE FORMULA

$$(n-1)A_{n+1} = (n^2-1)A_n + (n+1)A_{n-1} + 4(-1)^n, \quad (1)$$

with $A_1 = A_2 = 1$. A closed form expression due to Touchard (1934) is

$$A_n = \sum_{k=0}^n \frac{2n}{2n-k}\binom{2n-k}{k}(n-k)!(-1)^k, \quad (2)$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT (Vardi 1991). The sum can be evaluated explicitly as

$$A_n = \frac{n\pi I_{-n}(2)\csc(n\pi)}{e^2}$$

$$-\frac{4(-1)^n}{n^2-1}\,{}_2F_2(1, \tfrac{3}{2}; 2-n, 2-n, 2+n; -4), \quad (3)$$

where ${}_2F_2(a, b; c, d; x)$ is a GENERALIZED HYPERGEOMETRIC FUNCTION.

The first few values of A_n are $-1, 1, 0, 2, 13, 80, 579$, ... (Sloane's A000179), which are sometimes called MÉNAGE NUMBERS. The desired solution is then $2n!A_n$. The numbers A_n can be considered a special case of a restricted ROOKS PROBLEM.

Martingale

A sequence of random variates X_0, X_1, ... with finite means such that the conditional expectation of X_{n+1} given $X_0, X_1, X_2, ..., X_n$ is equal to X_n, i.e.,

$$\langle x_{n+1} | X_0, \ldots, X_n \rangle = X_n$$

(Feller 1971, p. 210). The term was first used to describe a type of wagering in which the bet is doubled or halved after a loss or win, respectively. The concept of martingales is due to Lévy, and it was developed extensively by Doob.

A 1-D RANDOM WALK with steps equally likely in either direction ($p = q = 1/2$) is an example of a martingale.

Mascheroni Constant

EULER-MASCHERONI CONSTANT

Mascheroni Construction

A geometric construction done with a movable COMPASS alone. All constructions possible with a COMPASS and STRAIGHTEDGE are possible with a *movable* COMPASS alone, as was proved by Mascheroni (1797). Mascheroni's results are now known to have been anticipated largely by Mohr (1672).

An example of a Mascheroni construction of the midpoint M of a LINE SEGMENT specified by two points A and B illustrated above (Steinhaus 1983, Wells 1991). Without loss of generality, take $AB = 1$.

1. Construct circles centered at A and B passing through B and A. These are unit circles centered at (0, 0) and (1, 0).
2. Locate C, the indicated intersection of circles A and B, and draw a circle centered on C passing through points A and B. This circle has center $(1/2, \sqrt{3}/2)$ and radius 1.
3. Locate D, the indicated intersection of circles B and C, and draw a circle centered on C passing

through points B and C. This circle has center (3/2, $\sqrt{3}/2$) and radius 1.
4. Locate E, the indicated intersection of circles B and D, and draw a circle centers on E passing through point C. This circle has center (2, 0) and radius $\sqrt{3}$.
5. Locate F and G, the intersections of circles AE and EC. These points are located at positions (5/4, $\pm\sqrt{39}/4$).
6. Locate M, the intersection of circles F and G. This point has position (1/2, 0), and is therefore the desired MIDPOINT of $\overline{AB}$.

Pedoe (1995, pp. xviii-xix) also gives a Mascheroni solution.

Maschke's Theorem

If a MATRIX GROUP is reducible, then it is completely reducible, i.e., if the MATRIX GROUP is equivalent to the MATRIX GROUP in which every MATRIX has the reduced form

$$\begin{bmatrix} D_i^{(1)} & X_i \\ 0 & D_i^{(2)} \end{bmatrix},$$

then it is equivalent to the MATRIX GROUP obtained by putting $X_i = 0$.

Mason's abc Theorem

MASON'S THEOREM

Mason's Theorem

Let there be three POLYNOMIALS $a(x)$, $b(x)$, and $c(x)$ with no common factors such that

$$a(x) + b(x) = c(x).$$

Then the number of distinct ROOTS of the three POLYNOMIALS is one or more greater than their largest degree. The theorem was first proved by Stothers (1981).

Mason's theorem may be viewed as a very special case of a Wronskian estimate (Chudnovsky and Chudnovsky 1984). The corresponding Wronskian identity in the proof by Lang (1993) is

$$c^3 * W(a,\ b,\ c) = W(W(a,\ c),\ W(b,\ c)),$$

so if a, b, and c are linearly dependent, then so are $W(a,\ c)$ and $W(b,\ c)$. More powerful Wronskian estimates with applications toward Diophantine approximation of solutions of linear differential equations may be found in Chudnovsky and Chudnovsky (1984) and Osgood (1985).

The RATIONAL FUNCTION case of FERMAT'S LAST THEOREM follows trivially from Mason's theorem (Lang 1993, p. 195).

Masser-Gramain Constant

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Let $f(z)$ be an ENTIRE FUNCTION such that $f(n)$ is an INTEGER for each POSITIVE INTEGER n. Then Pólya (1915) showed that if

$$\limsup_{r\to\infty} \frac{\ln M_r}{r} < \ln 2 = 0.693\ldots, \quad (1)$$

where

$$M_r = \sup_{|z|\le r} |f(x)| \quad (2)$$

is the SUPREMUM, then f is a POLYNOMIAL. Furthermore, ln 2 is the best constant (i.e., counterexamples exist for every smaller value).

If $f(z)$ is an ENTIRE FUNCTION with $f(n)$ a GAUSSIAN INTEGER for each GAUSSIAN INTEGER n, then Gelfond (1929) proved that there exists a constant α such that

$$\limsup_{r\to\infty} \frac{\ln M_r}{r^2} < \alpha \quad (3)$$

implies that f is a POLYNOMIAL. Gramain (1981, 1982) showed that the best such constant is

$$\alpha = \frac{\pi}{2e} = 0.578\ldots \quad (4)$$

Maser (1980) proved the weaker result that f must be a POLYNOMIAL if

$$\limsup_{r\to\infty} \frac{\ln M_r}{r^2} < \alpha_0 = \tfrac{1}{2}\exp\left(-\delta + \frac{4c}{\pi}\right), \quad (5)$$

where

$$c = \gamma\beta(1) + \beta'(1) = 0.6424543989481 14\ldots, \quad (6)$$

γ is the EULER-MASCHERONI CONSTANT, $\beta(z)$ is the DIRICHLET BETA FUNCTION,

$$\delta \equiv \lim_{n\to\infty}\left(\sum_{k=2}^{n} \frac{1}{\pi r_k^2} - \ln n\right), \quad (7)$$

and r_k is the minimum NONNEGATIVE r for which there exists a COMPLEX NUMBER z for which the CLOSED DISK with center z and radius r contains at least k distinct GAUSSIAN INTEGERS. Gosper gave

$$c = \pi\left\{-\ln[\Gamma(\tfrac{1}{4})] + \tfrac{3}{4}\pi + \tfrac{1}{2}\ln 2 + \tfrac{1}{2}\gamma\right\}. \quad (8)$$

Gramain and Weber (1985, 1987) have obtained

$$1.811447299 < \delta < 1.897327177, \quad (9)$$

which implies

$$0.1707339 < \alpha_0 < 0.1860446. \quad (10)$$

Gramain (1981, 1982) conjectured that

$$\alpha_0 = \frac{1}{2e}, \quad (11)$$

which would imply

$$\delta = 1 + \frac{4c}{\pi} = 1.822825249\ldots. \quad (12)$$

Matching

A matching on a GRAPH G is a set of edges of G such that no two of them share a vertex in common. The largest possible matching consists of $n/2$ edges, and such a matching is called a perfect matching. Although not all graphs have perfect matchings, a maximum matching exists for each graph.

The maximum matching in a BIPARTITE GRAPH can be found using `BipartiteMatching[g]` in the *Mathematica* add-on package `DiscreteMath'Combinatorica'` (which can be loaded with the command `<<DiscreteMath'`). The maximum matching on a general graph can be found using `MaximalMatching[g]` in the same package.

Match Problem

Given n matches (i.e., rigid unit line segments), find the number of topologically distinct planar arrangements which can be made (Gardner 1991). In this problem, two matches laid end-to-end with no third match at their meeting point are considered equivalent to a single match, so triangles are equivalent to squares, n-match tails are equivalent to 1-match tails, etc.

Solutions to the match problem are PLANAR TOPOLOGICAL GRAPHS on e edges, and the first few values for $e = 1$, 1, 3, 5, 10, 19, 39, ... (Sloane's A003055).

Matchstick Construction

Every point which can be constructed with a STRAIGHTEDGE and COMPASS, and no other points, can be constructed using identical matchsticks (i.e., identical movable line segments). Wells (1991) gives matchstick constructions which bisect a line segment and construct a SQUARE.

Matchstick Graph

A PLANAR GRAPH whose EDGES are all unit line segments. The minimal number of EDGES for matchstick graphs of various degrees are given in the table below. The minimal degree 1 matchstick graph is a single EDGE, and the minimal degree 2 graph is an EQUILATERAL TRIANGLE.

Mathematical Induction

INDUCTION

Mathematics

Mathematics is a broad-ranging field of study in which the properties and interactions of idealized objects are examined. Whereas mathematics began merely as a calculational tool for computation and tabulation of quantities, it has blossomed into an extremely rich and diverse set of tools, terminologies, and approaches which range from the purely abstract to the utilitarian.

Bertrand Russell once whimsically defined mathematics as "The subject in which we never know what we are talking about nor whether what we are saying is true" (Bergamini 1969).

The term "mathematics" is often shortened to "math" in informal American speech and, consistent with the British penchant for adding superfluous letters, "maths" in British English.

See also METAMATHEMATICS

References

Bergamini, D. *Mathematics.* New York: Time-Life Books, p. 9, 1969.

Mathematics Contests

There are several regular mathematics competitions available to students. The International Mathematical Olympiad is perhaps the largest, while the William Lowell Putnam Competition is another important contest.

The International Mathematical Olympiad (IMO) is the yearly world championship of mathematics for

high school students and is held in a different country each year. The first IMO was held in 1959 in Romania, but the contest has gradually expanded to include students from more than 80 different countries.

The William Lowell Putnam Mathematics Competition is a North American math contest for college students. Each year, on the first Saturday in December, more than 2000 students spend six hours in two sittings trying to solve 12 problems. The majority of the problems are very difficult, in the sense that their solution may require a nonstandard and creative approach. It is very rare for students to be able to solve all the problems, let alone the majority of them. The test can be taken both by individual and by teams, and the winners or their schools receive a small monetary compensation. Results for a given exam usually become available in early April of the following year.

The International Mathematical Contest in Modeling (MCM) is a competition that challenges teams of undergraduate students to clarify, analyze, and propose solutions to open-ended problems. Problems are chosen with the advice of experts in industry and government, and the best papers are submitted to be published in professional journals.

Mathematics Prizes

Several prizes are awarded periodically for outstanding mathematical achievement. There is no Nobel Prize in mathematics, and the most prestigious mathematical award is known as the FIELDS MEDAL. In rough order of importance, other awards are the $100,000 Wolf Prize of the Wolf Foundation of Israel, the Leroy P. Steele Prize of the American Mathematical Society, followed by the Bôcher Memorial Prize, Frank Nelson Cole Prizes in Algebra and Number Theory, and the Delbert Ray Fulkerson Prize, all presented by the American Mathematical Society.

The Clay Mathematics Institute of Cambridge, Massachusetts (CMI) has named seven "Millennium Prize Problems," selected by focusing on important classic questions in mathematics that have resisted solution over the years. A $7 million prize fund has been established for the solution to these problems, with $1 million allocated to each. The problems consist of the RIEMANN HYPOTHESIS, POINCARÉ CONJECTURE, HODGE CONJECTURE, SWINNERTON-DYER CONJECTURE, solution of the Navier-Stokes equation, formulation of Yang-Mills theory , and determination of whether NP-PROBLEMS are actually P-PROBLEMS.

MATHIEU FUNCTION

Mathieu Differential Equation

$$\frac{d^2V}{dv^2} + [a - 2q\cos(2v)]V = 0 \tag{1}$$

(Abramowitz and Stegun 1972; Zwillinger 1997, p. 125), having solution

$$y = C_1 C(a, q, v) + C_2 S(a, q, v), \tag{2}$$

where $C(a, q, v)$ and $S(a, q, v)$ are MATHIEU FUNCTIONS. The equation arises in separation of variables of the HELMHOLTZ DIFFERENTIAL EQUATION in ELLIPTIC CYLINDRICAL COORDINATES. Whittaker and Wat-

son (1990) use a slightly different form to define the MATHIEU FUNCTIONS.

The modified Mathieu differential equation

$$\frac{d^2U}{du^2} - [a - 2q\cosh(2u)]U = 0 \qquad (3)$$

(Iyanaga and Kawada 1980, p. 847; Zwillinger 1997, p. 125) arises in SEPARATION OF VARIABLES of the HELMHOLTZ DIFFERENTIAL EQUATION in ELLIPTIC CYLINDRICAL COORDINATES, and has solutions

$$y = C_1 C(a, q, -iu) + C_2 S(a, q - iu). \qquad (4)$$

The associated Mathieu differential equation is given by

$$y'' + [(1-2r)\cot x]y' + (a + k^2\cos^2 x)y = 0 \qquad (5)$$

(Ince 1956, p. 403; Zwillinger 1997, p. 125).

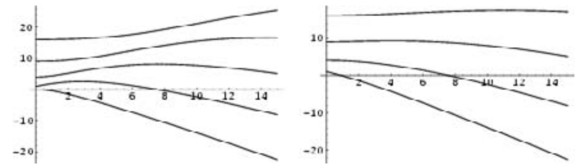
Mathieu Function



The Mathieu functions are the solutions to the MATHIEU DIFFERENTIAL EQUATION

$$\frac{d^2V}{dv^2} - [a - 2q\cos(2v)]V = 0. \qquad (1)$$

Even solutions are denoted $C(a, q, z)$ and odd solutions by $S(a, q, z)$. These are returned by the *Mathematica* functions MathieuC[a, q, z] and MathieuS[a, q, z], respectively. These functions appear in physical problems involving elliptical shapes or periodic potentials. The Mathieu functions have the special values

$$C(a, 0, z) = \cos(\sqrt{a}z) \qquad (2)$$

$$S(a, 0, z) = \sin(\sqrt{a}z). \qquad (3)$$

For nonzero q, the Mathieu functions are only periodic in z for certain values of a. Such characteristic values are given by the *Mathematica* functions MathieuCharacteristicA[r, q] and MathieuCharacteristicB[r, q] with r an integer or rational number. These values are often denoted a_r and b_r. For integer r, the even and odd Mathieu functions with characteristic values a_r and b_r are often denoted $ce_r(z, q)$ and $se_r(z, q)$, respectively (Abramowitz and Stegun 1972, p. 725). The left plot above shows a_r for $r = 0, 1, ..., 4$ and the right plot shows b_r for $r = 1, ..., 4$.

Whittaker and Watson (1990, p. 405) define the Mathieu function based on the equation

$$\frac{d^2u}{dz^2} + [a + 16q\cos(2z)]u = 0. \qquad (4)$$

This equation is closely related to HILL'S DIFFERENTIAL EQUATION. For an EVEN Mathieu function,

$$G(\eta) = \lambda \int_{-\pi}^{\pi} e^{k\cos\eta\cos\theta} G(\theta)\, d\theta, \qquad (5)$$

where $k \equiv \sqrt{32q}$. For an ODD Mathieu function,

$$G(\eta) = \lambda \int_{-\pi}^{\pi} \sin(k\sin\eta\sin\theta) G(\theta)\, d\theta. \qquad (6)$$

Both EVEN and ODD functions satisfy

$$G(\eta) = \lambda \int_{-\pi}^{\pi} e^{ik\sin\eta\sin\theta} G(\theta)\, d\theta. \qquad (7)$$

Letting $\zeta \equiv \cos^2 z$ transforms the MATHIEU DIFFERENTIAL EQUATION to

$$4\zeta(1-\zeta)\frac{d^2u}{d\zeta^2} + 2(1-2\zeta)\frac{du}{d\zeta} + (a - 16q + 32q\zeta)u = 0. \qquad (8)$$

Mathieu Groups

The first SIMPLE SPORADIC GROUPS discovered. M_{11}, M_{12}, M_{22}, M_{23}, M_{24} were discovered in 1861 and 1873 by Mathieu. Frobenius showed that all the Mathieu groups are SUBGROUPS of M_{24}.

The Mathieu groups are most simply defined as AUTOMORPHISM GROUPS of STEINER SYSTEMS, as summarized in the following table.

Mathieu group	Steiner system
M_{11}	$S(4, 5, 11)$
M_{12}	$S(5, 6, 12)$
M_{22}	$S(3, 6, 22)$
M_{23}	$S(4, 7, 23)$
M_{24}	$S(5, 8, 24)$

M_{11} and M_{23} are TRANSITIVE PERMUTATION GROUPS of 11 and 23 elements. The ORDERS of the Mathieu groups are

$$|M_{11}| = 2^4 \cdot 3^2 \cdot 5 \cdot 11$$

$$|M_{12}| = 2^6 \cdot 3^3 \cdot 5 \cdot 11$$

$$|M_{22}| = 2^7 \cdot 3^2 \cdot 5 \cdot 7 \cdot 11$$

$$|M_{23}| = 2^7 \cdot 3^2 \cdot 5 \cdot 7 \cdot 11 \cdot 23$$

$$|M_{24}| = 2^{10} \cdot 3^3 \cdot 5 \cdot 7 \cdot 11 \cdot 23.$$

MathieuS

MATHIEU FUNCTION

MathieuSPrime

MATHIEU FUNCTION

Matrix

The TRANSFORMATION given by the system of equations

$$x'_1 = a_{11}x_1 + a_{12}x_2 + \ldots + a_{1n}x_n$$

$$x'_2 = a_{21}x_1 + a_{22}x_2 + \ldots + a_{2n}x_n$$

$$\vdots$$

$$x'_m = a_{m1}x_1 + a_{m2}x_2 + \ldots + a_{mn}x_n$$

is denoted by the MATRIX EQUATION

$$\begin{bmatrix} x'_1 \\ x'_2 \\ \vdots \\ x'_m \end{bmatrix} = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1} & a_{m2} & \cdots & a_{mn} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{bmatrix}.$$

In concise notation, this could be written

$$\mathbf{x}' = \mathsf{A}\mathbf{x},$$

where $\mathbf{x}'$ and $\mathbf{x}$ are VECTORS and A is called an $m \times n$ matrix. An $m \times n$ matrix consists of m rows and n columns, and the set of $m \times n$ matrices with real coefficients is sometimes denoted $\mathbb{R}^{m \times n}$. To remember which index refers to which direction, identify the indices of the last (i.e., lower right) term, so the indices m, n of the last element in the above matrix identifies it as an $m \times n$ matrix.

A matrix is said to be SQUARE if $m = n$, and RECTANGULAR if $m \neq n$. An $m \times 1$ matrix is called a COLUMN VECTOR, and a $1 \times n$ matrix is called a ROW VECTOR. Special types of SQUARE MATRICES include the IDENTITY MATRIX I, with A_2A_3 (where δ_{ij} is the KRONECKER DELTA) and the DIAGONAL MATRIX $a_{ij} = c_i\delta_{ij}$ (where c_i are a set of constants).

For every linear transformation there exists one and only one corresponding matrix. Conversely, every matrix corresponds to a unique linear transformation. The matrix is an important concept in mathematics, and was first formulated by Sylvester and Cayley.

Two matrices may be added (MATRIX ADDITION) or multiplied (MATRIX MULTIPLICATION) together to yield a new matrix. Other common operations on a single matrix are diagonalization, inversion (MATRIX INVERSE), and transposition (matrix TRANSPOSE). The DETERMINANT $\det(\mathsf{A})$ or $|\mathsf{A}|$ of a matrix A is a very important quantity which appears in many diverse applications. Matrices provide a concise notation which is extremely useful in a wide range of problems involving linear equations (e.g., LEAST SQUARES FITTING).

Matrix Addition

Denote the sum of two MATRICES A and B (of the same dimensions) by $\mathsf{C}=\mathsf{A}+\mathsf{B}$. The sum is defined by adding entries with the same indices

$$c_{ij} \equiv a_{ij} + b_{ij}$$

over all i and j. For example,

$$\begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} + \begin{bmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \end{bmatrix} = \begin{bmatrix} a_{11}+b_{11} & a_{12}+b_{12} \\ a_{21}+b_{21} & a_{22}+b_{22} \end{bmatrix}.$$

Matrix addition is therefore both COMMUTATIVE and ASSOCIATIVE.

See also MATRIX, MATRIX MULTIPLICATION

Matrix Decomposition

Matrix decomposition refers to the transformation of a given matrix (often assumed to be a SQUARE MATRIX) into a given canonical form.

See also CHOLESKY DECOMPOSITION, JORDAN MATRIX DECOMPOSITION, MATRIX DECOMPOSITION THEOREM, LQ DECOMPOSITION, LU DECOMPOSITION, ORTHOGONAL DECOMPOSITION, QR DECOMPOSITION, SCHUR DECOMPOSITION, SINGULAR VALUE DECOMPOSITION

Matrix Decomposition Theorem

Let P be a MATRIX of EIGENVECTORS of a given MATRIX A and D a MATRIX of the corresponding EIGENVALUES. Then A can be written

$$\mathsf{A} = \mathsf{PDP}^{-1}, \tag{1}$$

where D is a DIAGONAL MATRIX and the columns of P are ORTHOGONAL VECTORS. If P is not a SQUARE MATRIX, then it cannot have a MATRIX INVERSE. However, if P is $m \times n$ (with $m > n$), then A can be written using a so-called SINGULAR VALUE DECOMPOSITION OF THE FORM

$$\mathsf{A} = \mathsf{UDV}^{\mathrm{T}}, \tag{2}$$

where U and V are $n \times n$ SQUARE MATRICES with ORTHOGONAL columns so that

$$\mathsf{U}^{\mathrm{T}}\mathsf{U} = \mathsf{V}^{\mathrm{T}}\mathsf{V} = 1. \tag{3}$$

See also SINGULAR VALUE DECOMPOSITION

References

Press, W. H.; Flannery, B. P.; Teukolsky, S. A.; and Vetterling, W. T. "Singular Value Decomposition." §2.6 in *Numerical Recipes in FORTRAN: The Art of Scientific Computing, 2nd ed.* Cambridge, England: Cambridge University Press, pp. 51–3, 1992.

Matrix Diagonalization

Diagonalizing a MATRIX is equivalent to finding the EIGENVECTORS and EIGENVALUES. The EIGENVALUES make up the entries of the diagonalized MATRIX, and the EIGENVECTORS make up the new set of axes corresponding to the DIAGONAL MATRIX.

See also DIAGONAL MATRIX, EIGENVALUE, EIGENVECTOR

References

Arfken, G. "Diagonalization of Matrices." §4.6 in *Mathematical Methods for Physicists, 3rd ed.* Orlando, FL: Academic Press, pp. 217–29, 1985.

Matrix Direct Product

The matrix direct product gives the MATRIX of the LINEAR TRANSFORMATION induced by the TENSOR PRODUCT of the original VECTOR SPACES. More precisely, suppose that

$$S : V_1 \to W_1 \quad (1)$$

and

$$T : V_2 \to W_2 \quad (2)$$

are given by $S(x) = Ax$ and $T(y) = By$. Then

$$S \otimes T : V_1 \otimes V_2 \to W_1 \otimes W_2 \quad (3)$$

is determined by

$$S \otimes T(x \otimes y) = (Ax) \otimes (By) = (A \otimes B)(x \otimes y). \quad (4)$$

Given an $m \times n$ MATRIX A and a $p \times q$ MATRIX B, their direct product $\mathsf{C} = \mathsf{A} \otimes \mathsf{B}$ is an $(mp) \times (nq)$ MATRIX with elements defined by

$$c_{\alpha\beta} = a_{ij} b_{kl}, \quad (5)$$

where

$$\alpha \equiv p(i-1)+k \quad (6)$$

$$\beta \equiv q(j-1)+l. \quad (7)$$

In *Mathematica*, the matrix direct product can be formed using the following code.

```
< <LinearAlgebra`MatrixManipulation`;
          MatrixDirectProduct[a_List?MatrixQ,
b_List?MatrixQ] : =
   BlockMatrix[Outer[Times, a, b]]
  ]
```

For example, the matrix direct product of the 2×2 MATRIX A and the 3×2 MATRIX B is given by the following 6×4 MATRIX,

$$\mathsf{A} \otimes \mathsf{B} = \begin{bmatrix} a_{11}\mathsf{B} & a_{12}\mathsf{B} \\ a_{21}\mathsf{B} & a_{22}\mathsf{B} \end{bmatrix} \quad (8)$$

$$= \begin{bmatrix} a_{11}b_{11} & a_{11}b_{12} & a_{12}b_{11} & a_{12}b_{12} \\ a_{11}b_{21} & a_{11}b_{22} & a_{12}b_{21} & a_{12}b_{22} \\ a_{11}b_{31} & a_{11}b_{32} & a_{12}b_{31} & a_{12}b_{32} \\ a_{21}b_{11} & a_{21}b_{12} & a_{22}b_{11} & a_{22}b_{12} \\ a_{21}b_{21} & a_{21}b_{22} & a_{22}b_{21} & a_{22}b_{22} \\ a_{21}b_{31} & a_{21}b_{32} & a_{22}b_{31} & a_{22}b_{32} \end{bmatrix}. \quad (9)$$

See also DIRECT PRODUCT, MATRIX MULTIPLICATION, TENSOR DIRECT PRODUCT

References

Schafer, R. D. *An Introduction to Nonassociative Algebras.* New York: Dover, p. 12, 1996.

Matrix Direct Sum

The construction of a BLOCK MATRIX from a set of SQUARE MATRICES, i.e.,

$$\otimes_{i=1}^{n} \mathsf{A}_i = \mathrm{diag}(\mathsf{A}_1, \mathsf{A}_2, \ldots, \mathsf{A}_n) = \begin{bmatrix} \mathsf{A}_1 & & & \\ & \mathsf{A}_2 & & \\ & & \ddots & \\ & & & \mathsf{A}_n \end{bmatrix}.$$

See also BLOCK MATRIX

References

Ayres, F. Jr. *Theory and Problems of Matrices.* New York: Schaum, pp. 13–4, 1962.

Matrix Equality

Two MATRICES A and B are said to be equal IFF

$$a_{ij} \equiv b_{ij}$$

for all i, j. Therefore,

$$\begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix} = \begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix},$$

while

$$\begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix} \neq \begin{bmatrix} 0 & 2 \\ 3 & 4 \end{bmatrix}.$$

See also EQUIVALENT MATRIX

Matrix Equation

Nonhomogeneous matrix equations OF THE FORM

$$\mathsf{A}\mathbf{x} = \mathbf{b} \quad (1)$$

can be solved by taking the MATRIX INVERSE to obtain

$$\mathbf{x} = \mathsf{A}^{-1}\mathbf{b}. \quad (2)$$

This equation will have a nontrivial solution IFF the DETERMINANT $\det(\mathsf{A}) \neq 0$. In general, more numerically stable techniques of solving the equation include GAUSSIAN ELIMINATION, LU DECOMPOSITION, or the SQUARE ROOT METHOD.

For a homogeneous $n \times n$ MATRIX equation

$$\begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ \vdots \\ 0 \end{bmatrix} \quad (3)$$

to be solved for the x_is, consider the DETERMINANT

$$\begin{vmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{vmatrix}. \quad (4)$$

Now multiply by x_1, which is equivalent to multiplying the first column (or any column) by x_1,

$$x_1 \begin{vmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{vmatrix} = \begin{vmatrix} a_{11}x_1 & a_{12} & \cdots & a_{1n} \\ a_{21}x_1 & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1}x_1 & a_{n2} & \cdots & a_{nn} \end{vmatrix}. \quad (5)$$

The value of the DETERMINANT is unchanged if multiples of columns are added to other columns. So add x_2 times column 2, ..., and x_n times column n to the first column to obtain

$$x_1 \begin{vmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{vmatrix}$$

$$= \begin{vmatrix} a_{11}x_1 + a_{12}x_2 + \ldots + a_{1n}x_n & a_{12} & \cdots & a_{1n} \\ a_{21}x_1 + a_{22}x_2 + \ldots + a_{2n}x_n & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1}x_1 + a_{n2}x_2 + \ldots + a_{nn}x_n & a_{n2} & \cdots & a_{nn} \end{vmatrix}. \quad (6)$$

But from the original MATRIX, each of the entries in the first columns is zero since

$$a_{i1}x_1 + a_{i2}x_2 + \ldots + a_{in}x_n = 0, \quad (7)$$

so

$$\begin{vmatrix} 0 & a_{12} & \cdots & a_{1n} \\ 0 & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & a_{n2} & \cdots & a_{nn} \end{vmatrix} = 0. \quad (8)$$

Therefore, if there is an $x_1 \neq 0$ which is a solution, the DETERMINANT is zero. This is also true for x_2, ..., x_n, so the original homogeneous system has a nontrivial solution for all x_is only if the DETERMINANT is 0. This approach is the basis for CRAMER'S RULE.

Given a numerical solution to a matrix equation, the solution can be iteratively improved using the following technique. Assume that the numerically obtained solution to

$$\mathsf{A}\mathbf{x} = \mathbf{b} \quad (9)$$

is $\mathbf{x}_1 = \mathbf{x} + \delta\mathbf{x}_1$, where $\delta\mathbf{x}_1$ is an error term. The first solution therefore gives

$$\mathsf{A}\mathbf{x}_1 = \mathsf{A}(\mathbf{x} + \delta\mathbf{x}_1) = \mathbf{b} + \delta\mathbf{b} \quad (10)$$

$$\mathsf{A}\delta\mathbf{x}_1 = \delta\mathbf{b}, \quad (11)$$

where $\delta\mathbf{b}$ is found by solving (10)

$$\delta\mathbf{b} = \mathsf{A}\mathbf{x}_1 - \mathbf{b}. \quad (12)$$

Combining (11) and (12) then gives

$$\delta\mathbf{x}_1 = \mathsf{A}^{-1}\delta\mathbf{b} = \mathsf{A}^{-1}(\mathsf{A}\mathbf{x}_1 - \mathbf{b}) = \mathbf{x}_1 - \mathsf{A}^{-1}\mathbf{b}. \quad (13)$$

See also CRAMER'S RULE, GAUSSIAN ELIMINATION, LU DECOMPOSITION, MATRIX, MATRIX ADDITION, MATRIX INVERSE, MATRIX MULTIPLICATION, NORMAL EQUATION, SQUARE ROOT METHOD

MatrixExp

MATRIX EXPONENTIAL

Matrix Exponential

The POWER SERIES that defines the EXPONENTIAL MAP e^x also defines a map between MATRICES. In particular,

$$\exp(\mathsf{A}) \equiv e^{\mathsf{A}} = \sum_{n=0}^{\infty} \frac{\mathsf{A}^n}{n!} \quad (1)$$

$$= \mathsf{I} + \mathsf{A} + \frac{\mathsf{AA}}{2!} + \frac{\mathsf{AAA}}{3!} + \ldots, \quad (2)$$

converges for any SQUARE MATRIX A, where I is the IDENTITY MATRIX. The matrix exponential is implemented in *Mathematica* as `MatrixExp[m]`.

In some cases, it is a simple matter to express the exponent. For example, when A is a DIAGONAL MATRIX, exponentiation can be performed simply by exponentiating each of the diagonal elements. For example, given a diagonal matrix

$$\mathsf{A} = \begin{bmatrix} a_1 & 0 & \cdots & 0 \\ 0 & a_2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & a_k \end{bmatrix}, \quad (3)$$

The matrix exponential is given by

$$\exp(\mathsf{A}) = \begin{bmatrix} e^{a_1} & 0 & \cdots & 0 \\ 0 & e^{a_2} & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & e^{a_k} \end{bmatrix}. \quad (4)$$

Since most matrices are DIAGONALIZABLE, it is easiest to diagonalize the matrix before exponentiating it.

When A is a NILPOTENT MATRIX, the exponential is given by a MATRIX POLYNOMIAL because some power of A vanishes. For example, when

$$\mathsf{A} = \begin{bmatrix} 0 & x & z \\ 0 & 0 & y \\ 0 & 0 & 0 \end{bmatrix}, \quad (5)$$

then

$$\exp(\mathsf{A}) = \begin{bmatrix} 1 & x & z + \frac{1}{2}xy \\ 0 & 1 & y \\ 0 & 0 & 1 \end{bmatrix} \quad (6)$$

and $\mathsf{A}^3 = 0$.

For the ZERO MATRIX $\mathsf{A}=0$,

$$e^0 = \mathsf{I}, \tag{7}$$

i.e., the IDENTITY MATRIX. In general,

$$e^{\mathsf{A}}e^{-\mathsf{A}} = e^0 = \mathsf{I}, \tag{8}$$

so the exponential of a matrix is always invertible, with inverse the exponent of the negative of the matrix. However, in general, the formula

$$e^{\mathsf{A}}e^{\mathsf{B}} = e^{\mathsf{A}+\mathsf{B}} \tag{9}$$

holds only when A and B COMMUTE, i.e.,

$$[A, B] = AB - BA = 0. \tag{10}$$

For example,

$$\exp\left(\begin{bmatrix}0 & -x\\ 0 & 0\end{bmatrix} + \begin{bmatrix}0 & 0\\ x & 0\end{bmatrix}\right) = \begin{bmatrix}\cos x & -\sin x\\ \sin x & \cos x\end{bmatrix}, \tag{11}$$

while

$$\exp\left(\begin{bmatrix}0 & -x\\ 0 & 0\end{bmatrix}\right)\exp\left(\begin{bmatrix}0 & 0\\ x & 0\end{bmatrix}\right) = \begin{bmatrix}1 & -x\\ 0 & 1\end{bmatrix}\begin{bmatrix}1 & 0\\ x & 1\end{bmatrix}$$

$$= \begin{bmatrix}1-x^2 & -x\\ x & 1\end{bmatrix}. \tag{12}$$

Matrix Fraction

A pair of matrices ND^{-1} or $\mathsf{D}^{-1}\mathsf{N}$, where N is the matrix NUMERATOR and D is the DENOMINATOR.

See also FRACTION

Matrix Group

A GROUP in which the elements are SQUARE MATRICES, the group multiplication law is MATRIX MULTIPLICATION, and the group inverse is simply the MATRIX INVERSE. Every matrix group is equivalent to a unitary matrix group (Lomont 1987, pp. 47–8).

See also MASCHKE'S THEOREM

References

Lomont, J. S. "Matrix Groups." §3.1 in *Applications of Finite Groups.* New York: Dover, pp. 46–2, 1987.

Matrix Inverse

The inverse of a SQUARE MATRIX A, sometimes called a reciprocal matrix, is a matrix A^{-1} such that

$$\mathsf{AA}^{-1} = \mathsf{I}, \tag{1}$$

where I is the IDENTITY MATRIX. Courant and Hilbert (1989, p. 10) use the notation $\check{\mathsf{A}}$ to denote the inverse matrix.

A SQUARE MATRIX A has an inverse IFF the DETERMINANT $|\mathsf{A}| \neq 0$ (Lipschutz 1991, p. 45) A matrix possessing an inverse is called NONSINGULAR, or invertible. The matrix inverse of a SQUARE MATRIX m may be taken in *Mathematica* using the function `Inverse[`m`]`.

For a 2×2 MATRIX

$$\mathsf{A} \equiv \begin{bmatrix}a & b\\ c & d\end{bmatrix}, \tag{2}$$

the inverse is

$$\mathsf{A}^{-1} = \frac{1}{|\mathsf{A}|}\begin{bmatrix}d & -b\\ -c & a\end{bmatrix} = \frac{1}{ad-bc}\begin{bmatrix}d & -b\\ -c & a\end{bmatrix}. \tag{3}$$

For a 3×3 MATRIX,

$$\mathsf{A}^{-1} = \frac{1}{|\mathsf{A}|}\begin{bmatrix}\begin{vmatrix}a_{22} & a_{23}\\ a_{32} & a_{33}\end{vmatrix} & \begin{vmatrix}a_{13} & a_{12}\\ a_{33} & a_{32}\end{vmatrix} & \begin{vmatrix}a_{12} & a_{13}\\ a_{22} & a_{23}\end{vmatrix}\\ \begin{vmatrix}a_{23} & a_{21}\\ a_{33} & a_{31}\end{vmatrix} & \begin{vmatrix}a_{11} & a_{13}\\ a_{31} & a_{33}\end{vmatrix} & \begin{vmatrix}a_{13} & a_{11}\\ a_{23} & a_{21}\end{vmatrix}\\ \begin{vmatrix}a_{21} & a_{22}\\ a_{31} & a_{32}\end{vmatrix} & \begin{vmatrix}a_{12} & a_{11}\\ a_{32} & a_{31}\end{vmatrix} & \begin{vmatrix}a_{11} & a_{12}\\ a_{21} & a_{22}\end{vmatrix}\end{bmatrix}. \tag{4}$$

A general $n\times n$ matrix can be inverted using methods such as the GAUSS-JORDAN ELIMINATION, GAUSSIAN ELIMINATION, or LU DECOMPOSITION.

The inverse of a PRODUCT AB of MATRICES A and B can be expressed in terms of A^{-1} and B^{-1}. Let

$$\mathsf{C} \equiv \mathsf{AB}. \tag{5}$$

Then

$$\mathsf{B} = \mathsf{A}^{-1}\mathsf{AB} = \mathsf{A}^{-1}\mathsf{C} \tag{6}$$

and

$$\mathsf{A} = \mathsf{ABB}^{-1} = \mathsf{CB}^{-1}. \tag{7}$$

Therefore,

$$\mathsf{C} = \mathsf{AB} = (\mathsf{CB}^{-1})(\mathsf{A}^{-1}\mathsf{C}) = \mathsf{CB}^{-1}\mathsf{A}^{-1}\mathsf{C}, \tag{8}$$

so

$$\mathsf{CB}^{-1}\mathsf{A}^{-1} = \mathsf{I}, \tag{9}$$

where I is the IDENTITY MATRIX, and

$$\mathsf{B}^{-1}\mathsf{A}^{-1} = \mathsf{C}^{-1} = (\mathsf{AB})^{-1}. \tag{10}$$

Matrix Multiplication

The product C of two MATRICES A and B is defined by

$$c_{ik} = a_{ij} b_{jk}, \tag{1}$$

where j is summed over for all possible values of i and k. Therefore, in order for multiplication to be defined, the dimensions of the MATRICES must satisfy

$$(n \times m)(m \times p) = (n \times p), \tag{2}$$

where $(a \times b)$ denotes a MATRIX with a rows and b columns. Writing out the product explicitly,

$$\begin{bmatrix} c_{11} & c_{12} & \cdots & c_{1p} \\ c_{21} & c_{22} & \cdots & c_{2p} \\ \vdots & \vdots & \ddots & \vdots \\ c_{n1} & c_{n2} & \cdots & c_{np} \end{bmatrix} = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1m} \\ a_{21} & a_{22} & \cdots & a_{2m} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nm} \end{bmatrix} \begin{bmatrix} b_{11} & b_{12} & \cdots & b_{1p} \\ b_{21} & b_{22} & \cdots & b_{2p} \\ \vdots & \vdots & \ddots & \vdots \\ b_{m1} & b_{m2} & \cdots & b_{mp} \end{bmatrix}, \tag{3}$$

where

$$\begin{aligned} c_{11} &= a_{11}b_{11} + a_{12}b_{21} + \ldots + a_{1m}b_{m1} \\ c_{12} &= a_{11}b_{12} + a_{12}b_{22} + \ldots + a_{1m}b_{m2} \\ c_{1p} &= a_{11}b_{1p} + a_{12}b_{2p} + \ldots + a_{1m}b_{mp} \\ c_{21} &= a_{21}b_{11} + a_{22}b_{21} + \ldots + a_{2m}b_{m1} \\ c_{22} &= a_{21}b_{12} + a_{22}b_{22} + \ldots + a_{2m}b_{m2} \\ c_{2p} &= a_{21}b_{1p} + a_{22}b_{2p} + \ldots + a_{2m}b_{mp} \\ c_{n1} &= a_{n1}b_{11} + a_{n2}b_{21} + \ldots + a_{nm}b_{m1} \\ c_{n2} &= a_{n1}b_{12} + a_{n2}b_{22} + \ldots + a_{nm}b_{m2} \\ c_{np} &= a_{n1}b_{1p} + a_{n2}b_{2p} + \ldots + a_{nm}b_{mp}. \end{aligned}$$

Matrix multiplication is ASSOCIATIVE, as can be seen by taking

$$[(ab)c]_{ij} = (ab)_{ik} c_{kj} = (a_{il} b_{lk}) c_{kj}. \tag{4}$$

Now, since a_{il}, b_{lk}, and c_{kj} are SCALARS, use the ASSOCIATIVITY of SCALAR MULTIPLICATION to write

$$(a_{il} b_{lk}) c_{kj} = a_{il}(b_{lk} c_{kj}) = a_{il}(bc)_{lj} = [a(bc)]_{ij}. \tag{5}$$

Since this is true for all i and j, it must be true that

$$(ab)c = a(bc). \tag{6}$$

That is, matrix multiplication is ASSOCIATIVE. However, matrix multiplication is *not*, in general, COMMUTATIVE (although it is COMMUTATIVE if A and B are DIAGONAL and of the same dimension).

The product of two BLOCK MATRICES is given by multiplying each block

$$\begin{bmatrix} o & o & & & & \\ o & o & & & & \\ & & o & & & \\ & & & o & o & o \\ & & & o & o & o \\ & & & o & o & o \end{bmatrix} \begin{bmatrix} x & x & & & & \\ x & x & & & & \\ & & x & & & \\ & & & x & x & x \\ & & & x & x & x \\ & & & x & x & x \end{bmatrix} = \begin{bmatrix} \begin{bmatrix} o & o \\ o & o \end{bmatrix} \begin{bmatrix} x & x \\ x & x \end{bmatrix} & & \\ & [o][x] & \\ & & \begin{bmatrix} o & o & o \\ o & o & o \\ o & o & o \end{bmatrix} \begin{bmatrix} x & x & x \\ x & x & x \\ x & x & x \end{bmatrix} \end{bmatrix}. \tag{7}$$

Matrix Norm

Given a SQUARE MATRIX A with COMPLEX (or REAL) entries, a MATRIX NORM $|A|$ is a NONNEGATIVE number associated with A having the properties

1. $||A|| > 0$ when $A \neq 0$ and $||A|| = 0$ IFF $A = 0$,
2. $||kA|| = |k| ||A||$ for any SCALAR k,
3. $||A + B|| \leq ||A|| + ||B||$,
4. $||AB|| \leq ||A|| ||B||$

For an $n \times n$ MATRIX A and an $n \times n$ UNITARY MATRIX U,

$$||AU|| = ||UA|| = ||A||.$$

Let λ_1, ..., λ_n be the EIGENVALUES of A, then

$$\frac{1}{||A^{-1}||} \leq |\lambda| \leq ||A||.$$

The MAXIMUM ABSOLUTE COLUMN SUM NORM $||A||_1$, SPECTRAL NORM $||A||_2$, and MAXIMUM ABSOLUTE ROW SUM NORM $||A||_\infty$ satisfy

$$||A||_2^2 \leq ||A||_1 \leq ||A||_\infty.$$

Matrix norms are implemented as `MatrixNorm[m, p]` in the *Mathematica* add-on package `LinearAlgebra`MatrixMultiplication`` (which can be loaded with the command `<<LinearAlgebra``), where $p = 1, 2$, or ∞.

For a SQUARE MATRIX, the SPECTRAL NORM, which is the SQUARE ROOT of the maximum EIGENVALUE of A^*A (where A^* is the ADJOINT MATRIX), is often referred to as "the" matrix norm.

See also COMPATIBLE, HILBERT-SCHMIDT NORM, MAXIMUM ABSOLUTE COLUMN SUM NORM, MAXIMUM ABSOLUTE ROW SUM NORM, NATURAL NORM, NORM, POLYNOMIAL NORM, SPECTRAL NORM, SPECTRAL RADIUS, VECTOR NORM

Matrix p-Norm

MATRIX NORM

Matrix Polynomial

A polynomial with matrix coefficients. An nth order matrix polynomial in a variable t is given by

$$P(t) = A_0 + A_1 t + A_2 t^2 + \ldots + A_n t^n, \tag{1}$$

where A_k are $p \times p$ square matrices.

If the entries of the matrices are real independent variates with a standard normal distribution, then the expected number of real solutions is given by

$$E_{n,p} = \sqrt{\pi}\, E\, \frac{\Gamma(\frac{1}{2}(p+1))}{\Gamma(\frac{1}{2}p)}, \tag{2}$$

where

$$E_n = \begin{cases} \sqrt{2}\sum_{k=0}^{n/2-1} \frac{(4k-1)!!}{(4k)!!} & \text{for } n \text{ even} \\ 1+\sqrt{2}\sum_{k=1}^{(n-1)/2} \frac{(4k-3)!!}{(4k-2)!!} & \text{for } n \text{ odd} \end{cases} \tag{3}$$

(Edelman and Kostlan 1995).

Matrix Polynomial Identity

CAYLEY-HAMILTON THEOREM

Matrix Power

The power A^n of a MATRIX A for n a nonnegative integer is defined as the MATRIX PRODUCT of n copies of A,

$$A^n = \underbrace{A \cdots A}_{n}.$$

A matrix to the zeroth power is defined to be the IDENTITY MATRIX of the same dimensions, $A^0 = I$. The MATRIX INVERSE is commonly denoted A^{-1}, which should not be interpreted to mean $1/A$.

Matroid

Roughly speaking, a matroid is a finite set together with a generalization of a concept from linear algebra that satisfies a natural set of properties for that concept. For example, the finite set could be the rows of a MATRIX, and the generalizing concept could be linear dependence and independence of any subset of rows of the MATRIX.

Formally, a matroid consists of a finite set M of elements together with a family $\mathfrak{C} = \{C_1, C_1, \ldots\}$ of nonempty subsets of M, called circuits, which satisfy the axioms

1. No PROPER SUBSET of a circuit is a circuit,
2. If $x \in C_1 \cap C_2$ and $C_1 \neq C_2$, then $C_1 \cup C_2 - \{x\}$ contains a circuit.

(Harary 1994, p. 40).

An equivalent definition considers a matroid as a finite set M of elements together with a family of subsets of M, called independent sets, such that

1. The EMPTY SET is independent,
2. Every SUBSET of an independent set is independent,
3. For every subset A of M, all maximal independent sets contained in A have the same number of elements.

(Harary 1994, pp. 40–1).

The number of simple matroids (or COMBINATORIAL GEOMETRIES) with $n = 0, 1, \ldots$ points are 1, 1, 2, 4, 9, 26, 101, 950, ... (Sloane's A002773), and the number of matroids on $n = 0, 1, \ldots$ points are 1, 2, 4, 8, 17, 38, 98, 306, 1724, ... (Sloane's A055545; Oxley 1993, p. 473). (The value for $n = 5$ given by Oxley 1993, p. 42, is incorrect.)

Max

MAXIMUM

Maximal Ideal

A maximal ideal of a RING R is an IDEAL I, not equal to R, such that there are no IDEALS "in between" I and R. In other words, if J is an IDEAL which contains I as a SUBSET, then either $J = I$ or $J = R$. For example, $n\mathbb{Z}$ is a maximal ideal of $\mathbb{Z}$ IFF n is PRIME, where $\mathbb{Z}$ is the RING of INTEGERS.

Only in a LOCAL RING is there just one maximal ideal. For instance, in the integers, $\mathfrak{a} = \langle p \rangle$ is a maximal ideal whenever p is prime.

A maximal ideal $\mathfrak{m}$ is always a PRIME IDEAL, and the QUOTIENT RING $A/\mathfrak{m}$ is always a FIELD. In general, not all prime ideals are maximal.

See also IDEAL, MAXIMAL IDEAL THEOREM, PRIME IDEAL, QUOTIENT RING, REGULAR LOCAL RING, RING

Maximal Ideal Theorem

The proposition that every PROPER IDEAL of a BOOLEAN ALGEBRA can be extended to a MAXIMAL IDEAL. It is equivalent to the BOOLEAN REPRESENTATION THEOREM, which can be proved without using the AXIOM OF CHOICE (Mendelson 1997, p. 121).

See also BOOLEAN REPRESENTATION THEOREM

Maximal Tori Theorem

Let T be a maximal torus of a group G, then T intersects every CONJUGACY CLASS of G, i.e., every element $g \in G$ is conjugate to a suitable element in T. The theorem is due to É. Cartan.

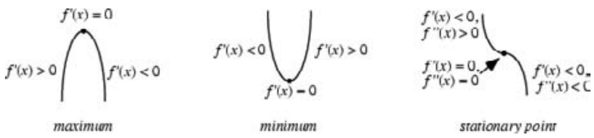
Maximal Zero-Sum-Free Set

A set having the largest number k of distinct residue classes modulo m so that no SUBSET has zero sum.



See also MAXIMAL SUM-FREE SET

References

Guy, R. K. "Maximal Zero-Sum-Free Sets." §C15 in *Unsolved Problems in Number Theory, 2nd ed.* New York: Springer-Verlag, pp. 129–31, 1994.

Maximum

The largest value of a set, function, etc. The maximum value of a set of elements $A = \{a_i\}_{i=1}^N$ is denoted max A or $\max_i a_i$, and is equal to the last element of a sorted (i.e., ordered) version of A. For example, given the set $\{3, 5, 4, 1\}$, the sorted version is $\{1, 3, 4, 5\}$, so the maximum is 5. The maximum and MINIMUM are the simplest ORDER STATISTICS.

A continuous FUNCTION may assume a maximum at a single point or may have maxima at a number of points. A GLOBAL MAXIMUM of a FUNCTION is the largest value in the entire RANGE of the FUNCTION, and a LOCAL MAXIMUM is the largest value in some local neighborhood.

For a function $f(x)$ which is CONTINUOUS at a point x_0, a NECESSARY but not SUFFICIENT condition for $f(x)$ to have a RELATIVE MAXIMUM at $x = x_0$ is that x_0 be a CRITICAL POINT (i.e., $f(x)$ is either not DIFFERENTIABLE at x_0 or x_0 is a STATIONARY POINT, in which case $f'(x_0) = 0$).

The FIRST DERIVATIVE TEST can be applied to CONTINUOUS FUNCTIONS to distinguish maxima from MINIMA. For twice differentiable functions of one variable, $f(x)$, or of two variables, $f(x, y)$, the SECOND DERIVATIVE TEST can sometimes also identify the nature of an EXTREMUM. For a function $f(x)$, the EXTREMUM TEST succeeds under more general conditions than the SECOND DERIVATIVE TEST.

See also CRITICAL POINT, EXTREMUM, EXTREMUM TEST, FIRST DERIVATIVE TEST, GLOBAL MAXIMUM, INFLECTION POINT, LOCAL MAXIMUM, MIDRANGE, MINIMUM, ORDER STATISTIC, SADDLE POINT (FUNCTION), SECOND DERIVATIVE TEST, STATIONARY POINT

Maximum Absolute Column Sum Norm

The NATURAL NORM induced by the L1-NORM is called the maximum absolute column sum norm and is defined by

$$\|\mathsf{A}\|_1 = \max_j \sum_{i=1}^{n} |a_{ij}|$$

for a MATRIX A. This MATRIX NORM is implemented as `MatrixNorm[`m`, 1]` in the *Mathematica* add-on package `LinearAlgebra'MatrixMultiplication'`

(which can be loaded with the command `<<LinearAlgebra``).

See also L_1-NORM, MATRIX NORM, MAXIMUM ABSOLUTE ROW SUM NORM, SPECTRAL NORM

Maximum Absolute Row Sum Norm

The NATURAL NORM induced by the L-INFINITY-NORM is called the maximum absolute row sum norm and is defined by

$$\|\mathsf{A}\|_\infty = \max_i \sum_{j=1}^{n} |a_{ij}|$$

for a MATRIX A. This MATRIX NORM is implemented as `MatrixNorm`[m, Infinity] in the *Mathematica* add-on package `LinearAlgebra`MatrixMultiplication`` (which can be loaded with the command `<<LinearAlgebra``).

See also L-INFINITY-NORM, MATRIX NORM, MAXIMUM ABSOLUTE COLUMN SUM NORM, SPECTRAL NORM

Maximum Clique Problem

PARTY PROBLEM

Maximum Entropy Method

A DECONVOLUTION ALGORITHM (sometimes abbreviated MEM) which functions by minimizing a smoothness function ("ENTROPY") in an image. Maximum entropy is also called the ALL-POLES MODEL or AUTOREGRESSIVE MODEL. For images with more than a million pixels, maximum entropy is faster than the CLEAN algorithm.

MEM is commonly employed in astronomical synthesis imaging. In this application, the resolution depends on the signal-to-noise ratio, which must be specified. Therefore, resolution is image dependent and varies across the map. MEM is also biased, since the ensemble average of the estimated noise is NONZERO. However, this bias is much smaller than the NOISE for pixels with a SNR$\gg$1. It can yield super-resolution, which can usually be trusted to an order of magnitude in SOLID ANGLE.

Two definitions of "ENTROPY" normalized to the flux in the image are

$$H_1 \equiv \sum_k \ln\left(\frac{I_k}{M_k}\right) \tag{1}$$

$$H_2 \equiv -\sum_k I_k \ln\left(\frac{I_k}{M_k e}\right), \tag{2}$$

where M_k is a "default image" and I_k is the smoothed image. Several unnormalized entropy measures (Cornwell 1982, p. 3) are given by

$$H_3 \equiv -\sum f_i \ln(f_i) \tag{3}$$

$$H_4 \equiv \sum \ln(f_i) \tag{4}$$

$$H_5 \equiv -\sum \frac{1}{\ln(f_i)} \tag{5}$$

$$H_6 \equiv -\sum \frac{1}{[\ln(f_i)]^2} \tag{6}$$

$$H_7 \equiv \sum \sqrt{\ln(f_i)}. \tag{7}$$

Maximum Flow, Minimum Cut Theorem

The maximum flow between vertices v_i and v_j in a GRAPH G is exactly the weight of the smallest set of edges to disconnect G with v_i and v_j in different components (Ford and Fulkerson 1962; Skiena 1990, p. 178).

Maximum Likelihood

The procedure of finding the value of one or more parameters for a given statistic which makes the *known* LIKELIHOOD distribution a MAXIMUM. The maximum likelihood estimate for a parameter μ is denoted $\hat{\mu}$.

For a BERNOULLI DISTRIBUTION,

$$\frac{d}{d\theta}\left[\binom{N}{N_p}\theta^{N_p}(1-\theta)^{N_q}\right]=N_p(1-\theta)-\theta N_q=0, \qquad (1)$$

so maximum likelihood occurs for $\theta=p$. If p is not known ahead of time, the likelihood function is

$$\begin{aligned}f(x_1,\ldots,x_n|p)&=P(X_1=x_1,\ldots,X_n=x_n|p)\\&=p^{x_1}(1-p)^{1-x_1}\cdots p^{x_n}(1-p)^{1-x_1 n}=p^{\sum x_i}(1-p)^{\Sigma(1-x_i)}\\&=p^{\sum x_i}(1-p)^{n-\sum x_i}, \qquad (2)\end{aligned}$$

where $x=0$ or 1, and $i=1, \ldots, n$.

$$\ln f=\sum x_i\ln p+\left(n-\sum x_i\right)\ln(1-p) \qquad (3)$$

$$\frac{d(\ln f)}{dp}=\frac{\sum x_i}{p}-\frac{n-\sum x_i}{1-p}=0 \qquad (4)$$

$$\sum x_i-p\sum x_i=np-p\sum x_i \qquad (5)$$

$$\hat{p}=\frac{\sum x_i}{n}. \qquad (6)$$

For a GAUSSIAN DISTRIBUTION,

$$\begin{aligned}f(x_1,\ldots,x_n|\mu,\sigma)&=\prod\frac{1}{\sigma\sqrt{2\pi}}\,e^{-(x_i-\mu)^2/2\sigma^2}\\&=\frac{(2\pi)^{-n/2}}{\sigma^n}\exp\left[-\frac{\sum(x_i-\mu)^2}{2\sigma^2}\right] \qquad (7)\end{aligned}$$

$$\ln f=-\tfrac{1}{2}n\ln(2\pi)-n\ln\sigma-\frac{\sum(x_i-\mu)^2}{2\sigma^2} \qquad (8)$$

$$\frac{\partial(\ln f)}{\partial\mu}=\frac{\sum(x_i-\mu)}{\sigma^2}=0 \qquad (9)$$

gives

$$\hat{\mu}=\frac{\sum x_i}{n}. \qquad (10)$$

$$\frac{\partial(\ln f)}{\partial\sigma}=-\frac{n}{\sigma}+\frac{\sum(x_i-\mu)^2}{\sigma^3} \qquad (11)$$

gives

$$\hat{\sigma}=\sqrt{\frac{\sum(x_i-\hat{\mu})^2}{n}}. \qquad (12)$$

Note that in this case, the maximum likelihood STANDARD DEVIATION is the sample STANDARD DEVIATION, which is a BIASED ESTIMATOR for the population STANDARD DEVIATION.

For a weighted GAUSSIAN DISTRIBUTION,

$$\begin{aligned}f(x_1,\ldots,x_n|\mu,\sigma)&=\prod\frac{1}{\sigma_i\sqrt{2\pi}}e^{-(x_i-\mu)^2/2\sigma_i^2}\\&=\frac{(2\pi)^{-n/2}}{\sigma^n}\exp\left[-\frac{\sum(x_i-\mu)^2}{2\sigma^2}\right] \qquad (13)\end{aligned}$$

$$\ln f=-\tfrac{1}{2}n\ln(2\pi)-n\sum\ln\sigma_i-\sum\frac{(x_i-\mu)^2}{2\sigma_i^2} \qquad (14)$$

$$\frac{\partial(\ln f)}{\partial\mu}=\sum\frac{(x_i-\mu)}{\sigma_i^2}=\sum\frac{x_i}{\sigma_i^2}-\mu\sum\frac{1}{\sigma_i^2}=0 \qquad (15)$$

gives

$$\hat{\mu}=\frac{\sum\frac{x_i}{\sigma_i^2}}{\sum\frac{1}{\sigma_i^2}}. \qquad (16)$$

The VARIANCE of the MEAN is then

$$\sigma_\mu^2=\sum\sigma_i^2\left(\frac{\partial\mu}{\partial x_i}\right)^2. \qquad (17)$$

But

$$\frac{\partial\mu}{\partial x_i}=\frac{\partial}{\partial x_i}\frac{\sum(x_i/\sigma_i^2)}{\sum(1/\sigma_i^2)}=\frac{1/\sigma_i^2}{\sum(1/\sigma_i^2)}. \qquad (18)$$

so

$$\begin{aligned}\sigma_\mu^2&=\sum\sigma_i^2\left(\frac{1/\sigma_i^2}{\sum(1/\sigma_i^2)}\right)^2\\&\sum\frac{1/\sigma_i^2}{\left[\sum(1/\sigma_i^2)\right]^2}=\frac{1}{\sum(1/\sigma_i^2)}. \qquad (19)\end{aligned}$$

For a POISSON DISTRIBUTION,

$$f(x_1,\ldots,x_n|\lambda)=\frac{e^{-\lambda}\lambda^{x_1}}{x_1!}\cdots\frac{e^{-\lambda}\lambda^{x_n}}{x_n!}=\frac{e^{-n\lambda}\lambda^{\sum x_i}}{x_1!\cdots x_n!} \qquad (20)$$

$$\ln f=-n\lambda+(\ln\lambda)\sum x_i-\ln\left(\prod x_i!\right) \qquad (21)$$

$$\frac{d(\ln f)}{\lambda}=-n+\frac{\sum x_i}{\lambda}=0 \qquad (22)$$

$$\hat{\lambda} = \frac{\sum x_i}{n}. \tag{23}$$

Maximum Modulus Principle

Let $U \subseteq \mathbb{C}$ be a DOMAIN, and let f be an ANALYTIC FUNCTION on U. Then if there is a point $z_0 \in U$ such that $|f(z_0)| \geq |f(z)|$ for all $z \in U$, then f is constant. The following slightly sharper version can also be formulated. Let $U \subseteq \mathbb{C}$ be a DOMAIN, and let f be an ANALYTIC FUNCTION on U. Then if there is a point $z_0 \in U$ at which $|f|$ has a LOCAL MAXIMUM, then f is constant.

Furthermore, let $U \subseteq \mathbb{C}$ be a bounded domain, and let f be a continuous function on the CLOSED SET $\bar{U}$ that is analytic on U. Then the maximum value of $|f|$ on $\bar{U}$ (which always exists) occurs on the boundary ∂U. In other words,

$$\max_{\bar{U}} |f| = \max_{\partial U} |f|.$$

The maximum modulus theorem is not always true on an unbounded domain.

Maxwell Distribution

The distribution of speeds of molecules in thermal equilibrium as given by statistical mechanics. The probability and cumulative distributions over the range $x \in [0, \infty)$ are

$$P(x) = \sqrt{\frac{2}{\pi}} a^{3/2} x^2 e^{-ax^2/2} \tag{1}$$

$$D(x) = \frac{2\gamma(\frac{3}{2}, \frac{1}{2}ax^2)}{\sqrt{\pi}} \tag{2}$$

$$= \operatorname{erf}\left(x\sqrt{\frac{a}{2}}\right) - e^{-ax^2/2}\sqrt{\frac{2a}{\pi}}, \tag{3}$$

where $\gamma(a, x)$ is an incomplete GAMMA FUNCTION and $\operatorname{erf}(x)$ is ERF. The RAW MOMENTS are

$$\mu'_n = \frac{2^{1+n/2} a^{-n/2} \Gamma(\frac{1}{2}(3+n))}{\sqrt{\pi}}. \tag{4}$$

$$\mu' = 2\sqrt{\frac{2}{\pi a}} \tag{5}$$

$$\mu'_2 = \frac{3}{a} \tag{6}$$

$$\mu'_3 = 8\sqrt{\frac{2}{a^3 \pi}} \tag{7}$$

$$\mu'_4 = \tfrac{15}{2} \tag{8}$$

(Papoulis 1984, p. 149), and the MEAN, VARIANCE, SKEWNESS, and KURTOSIS are given by

$$\mu = 2\sqrt{\frac{2}{\pi a}} \tag{9}$$

$$\sigma^2 = \frac{3\pi - 8}{\pi a} \tag{10}$$

$$\gamma_1 = \frac{8}{3}\sqrt{\frac{2}{3\pi}} \tag{11}$$

$$\gamma_2 = -\tfrac{4}{3}. \tag{12}$$

Maxwell Equations

The system of PARTIAL DIFFERENTIAL EQUATIONS describing classical electromagnetism and therefore of central importance in physics. In the so-called cgs system of units, the Maxwell equations are given by

$$\nabla \cdot \mathbf{D} = 4\pi\rho \tag{1}$$

$$\nabla \times \mathbf{E} = -\frac{1}{c}\frac{\partial \mathbf{B}}{\partial t} \tag{2}$$

$$\nabla \cdot \mathbf{B} = 0 \tag{3}$$

$$\nabla \times \mathbf{H} = \frac{4\pi}{c}\mathbf{J} + \frac{1}{c}\frac{\partial \mathbf{D}}{\partial t}, \tag{4}$$

where $\mathbf{D}$ is the effective electric field in a dielectric , ρ is the charge density, $\mathbf{E}$ is the electric field, c is the speed of light, $\mathbf{B}$ is the imposed magnetic field, $\mathbf{H}$ is the effective magnetic field in a dielectric, and $\mathbf{J}$ is the current density. As usual, $\nabla \cdot \mathbf{V}$ is the DIVERGENCE and $\nabla \times \mathbf{V}$ is the CURL.

In the MKS system of units, the equations are written

$$\nabla \cdot \mathbf{D} = \frac{\rho}{\epsilon_0} \tag{5}$$

$$\nabla \times \mathbf{E} = -\frac{\partial \mathbf{B}}{\partial t} \tag{6}$$

$$\nabla \cdot \mathbf{B} = 0 \tag{7}$$

$$\nabla \times \mathbf{H} = \mu_0\mathbf{J} + \epsilon_0\mu_0\frac{\partial \mathbf{D}}{\partial t}, \tag{8}$$

where ϵ_0 is the permittivity of free space and μ_0 is the permeability of free space.

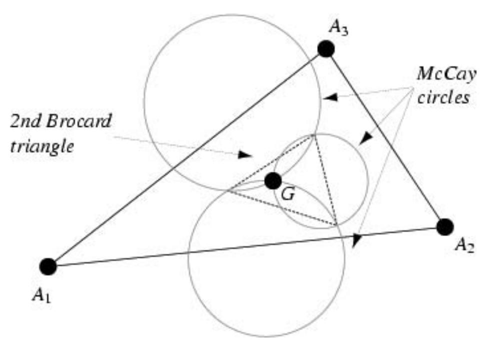
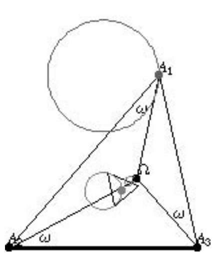
Mazur's Theorem



The generalization of the SCHÖNFLIES THEOREM to n-D. A smoothly embedded n-HYPERSPHERE in an $(n+1)$-HYPERSPHERE separates the $(n+1)$-HYPERSPHERE into two components, each HOMEOMORPHIC to $(n+1)$-BALLS. It can be proved using MORSE THEORY.

See also BALL, HYPERSPHERE, MORSE THEORY



M'Cay Circle

MCCAY CIRCLE

McCay Circle

The three circumcircles through the CENTROID G of a given triangle $\Delta A_1A_2A_3$ and the pairs of the vertices of the second BROCARD TRIANGLE are called the McCay circles (Johnson 1929, p. 306).

If the VERTEX A_1 of a TRIANGLE describes a NEUBERG CIRCLE N_1, then its CENTROID G describes one of the McCay circles (Johnson 1929, p. 290), which has RADIUS,

$$r = \tfrac{1}{6}a_1\sqrt{\cot^2\omega - 3},$$

1/3 that of the NEUBERG CIRCLE, where a_1 is the length of the edge A_2A_3 and ω is the BROCARD ANGLE (Johnson 1929, p. 307). In the above figure, the inner triangle is the second BROCARD TRIANGLE of $\Delta A_1A_2A_3$, whose two indicated edges are concyclic with G on the McCay circle.

McCoy's Theorem

If two SQUARE $n \times n$ MATRICES A and B are simultaneously upper triangularizable by similarity transforms, then there is an ordering $a_1, ..., a_n$ of the EIGENVALUES of A and $b_1, ..., b_n$ of the EIGENVALUES of B so that, given any POLYNOMIAL $p(x, y)$ in noncommuting variables, the EIGENVALUES of $p(A, B)$ are the numbers $p(a_i, b_i)$ with $i = 1, ..., n$. McCoy's theorem states the converse: If every POLYNOMIAL exhibits the correct EIGENVALUES in a consistent ordering, then A and B are simultaneously triangularizable.

McMahon's Theorem

PRICE'S THEOREM

McNugget Number

A number which can be obtained by adding together orders of McDonald's® Chicken McNuggets™ (prior to consuming any), which originally came in boxes of 6, 9, and 20. All integers are McNugget numbers except 1, 2, 3, 4, 5, 7, 8, 10, 11, 13, 14, 16, 17, 19, 22, 23, 25, 28, 31, 34, 37, and 43. Since the Happy Meal™-sized nugget box (4 to a box) can now be purchased separately, the modern McNugget numbers are LINEAR COMBINATIONS of 4, 6, 9, and 20. These new-fangled numbers are much less interesting than before, with only 1, 2, 3, 5, 7, and 11 remaining as non-McNugget numbers.

The GREEDY ALGORITHM can be used to find a McNugget expansion of a given INTEGER.

Mean

A mean is HOMOGENEOUS and has the property that a mean μ of a set of numbers x_i satisfies

$$\min(x_1, \ldots, x_n) \leq \mu \leq \max(x_1, \ldots, x_n).$$

There are several statistical quantities called means, e.g., ARITHMETIC-GEOMETRIC MEAN, GEOMETRIC MEAN, HARMONIC MEAN, QUADRATIC MEAN, ROOT-MEAN-SQUARE. However, the quantity referred to as "the" mean is the ARITHMETIC MEAN, also called the AVERAGE.

An interesting empirical relationship between the mean, median, and mode which appears to hold for unimodal curves of moderate asymmetry is given by

$$\text{mean} - \text{mode} \approx 3(\text{mean} - \text{median})$$

(Kenney and Keeping 1962, p. 53), which is the basis for the definition of the PEARSON MODE SKEWNESS.

See also ARITHMETIC-GEOMETRIC MEAN, AVERAGE, GENERALIZED MEAN, GEOMETRIC MEAN, HARMONIC MEAN, PEARSON MODE SKEWNESS, QUADRATIC MEAN, REVERSION TO THE MEAN, ROOT-MEAN-SQUARE

Mean Absolute Deviation

The mean absolute deviation (often inaccurately called the MEAN DEVIATION), is defined by

$$\text{M.A.D} = \frac{1}{N} \sum_{i=1}^{N} f_i |x_i - \bar{x}|,$$

where the SAMPLE SIZE is N, the samples have values x_i, the MEAN is $\bar{x}$, and f_i is an ABSOLUTE FREQUENCY.

s-CLUSTER

Mean Curvature

Let κ_1 and κ_2 be the PRINCIPAL CURVATURES, then their MEAN

$$H = \tfrac{1}{2}(\kappa_1 + \kappa_2) \quad (1)$$

is called the mean curvature. Let R_1 and R_2 be the radii corresponding to the PRINCIPAL CURVATURES, then the MULTIPLICATIVE INVERSE of the mean curvature H is given by the MULTIPLICATIVE INVERSE of the HARMONIC MEAN,

$$H \equiv \frac{1}{2}\left(\frac{1}{R_1} + \frac{1}{R_2}\right) = \frac{R_1 + R_2}{2R_1R_2}. \quad (2)$$

In terms of the GAUSSIAN CURVATURE K,

$$H = \tfrac{1}{2}(R_1 + R_2)K. \quad (3)$$

The mean curvature of a REGULAR SURFACE in $\mathbb{R}^3$ at a point $\mathbf{p}$ is formally defined as

$$H(p) = \tfrac{1}{2}\,\mathrm{Tr}(S(\mathbf{p})) \quad (4)$$

where S is the SHAPE OPERATOR and $\mathrm{Tr}(S)$ denotes the TRACE. For a MONGE PATCH with $z = h(x, y)$,

$$H = \frac{(1 + h_v^2)h_{uu} - 2h_u h_v h_{uv} + (1 + h_u^2)h_{vv}}{2(1 + h_u^2 + h_v^2)^{3/2}} \quad (5)$$

(Gray 1997, p. 399).

If $\mathbf{x} : U \to \mathbb{R}^3$ is a REGULAR PATCH, then the mean curvature is given by

$$H = \frac{eG - 2fF + gE}{2(EG - F^2)}, \quad (6)$$

where E, F, and G are coefficients of the first FUNDAMENTAL FORM and e, f, and g are coefficients of the second FUNDAMENTAL FORM (Gray 1997, p. 377). It can also be written

$$H = \frac{\det(\mathbf{x}_{uu}\mathbf{x}_u\mathbf{x}_v)|\mathbf{x}_u|^2 - 2\det(\mathbf{x}_{uv}\mathbf{x}_u\mathbf{x}_v)(\mathbf{x}_u \cdot \mathbf{x}_v)}{2[|\mathbf{x}_u|^2|\mathbf{x}_v| - (\mathbf{x}_u \cdot \mathbf{x}_v)^2]^{3/2}} + \frac{\det(\mathbf{x}_{vv}\mathbf{x}_u\mathbf{x}_v)|\mathbf{x}_u|^2}{2[|\mathbf{x}_u|^2|\mathbf{x}_v|^2 - (\mathbf{x}_u \cdot \mathbf{x}_v)^2]^{3/2}} \quad (7)$$

Gray (1997, p. 380).

The GAUSSIAN and mean curvature satisfy

$$H^2 \geq K, \quad (8)$$

with equality only at UMBILIC POINTS, since

$$H^2 - K = \tfrac{1}{4}(\kappa_1 - \kappa_2)^2. \quad (9)$$

If $\mathbf{p}$ is a point on a REGULAR SURFACE $M \subset \mathbb{R}^3$ and $\mathbf{v}_p$ and $\mathbf{w}_p$ are tangent vectors to M at $\mathbf{p}$, then the mean curvature of M at $\mathbf{p}$ is related to the SHAPE OPERATOR S by

$$S(\mathbf{v}_p) \times \mathbf{w}_p + \mathbf{v}_p \times S(\mathbf{w}_p) = 2H(\mathbf{p})\mathbf{v}_p \times \mathbf{w}_p \quad (10)$$

Let $\mathbf{Z}$ be a nonvanishing VECTOR FIELD on M which is everywhere PERPENDICULAR to M, and let V and W be VECTOR FIELDS tangent to M such that $V \times W = \mathbf{Z}$, then

$$H = -\frac{\mathbf{Z} \cdot (D_v\mathbf{Z} \times W + V \times D_W\mathbf{Z})}{2|\mathbf{Z}|^3} \quad (11)$$

(Gray 1997, p. 410).

Wente (1985, 1986, 1987) found a nonspherical finite surface with constant mean curvature, consisting of a self-intersecting three-lobed toroidal surface. A family of such surfaces exists.

Mean Deviation

The MEAN of the ABSOLUTE DEVIATIONS,

$$\mathrm{MD} \equiv \frac{1}{N}\sum_{i=1}^{N} |x_i - \bar{x}|,$$

where $\bar{x}$ is the MEAN of the distribution.

See also ABSOLUTE DEVIATION

Mean Distribution

For an infinite population with MEAN μ, VARIANCE σ^2, SKEWNESS γ_1, and KURTOSIS γ_2, the corresponding quantities for the *distribution of means* are

$$\mu_{\bar{x}} = \mu \tag{1}$$

$$\sigma^2_{\bar{x}} = \frac{\sigma^2}{N} \tag{2}$$

$$\gamma_{1,\,\bar{x}} = \frac{\gamma_1}{\sqrt{N}} \tag{3}$$

$$\gamma_{2,\,\bar{x}} = \frac{\gamma_2}{N}. \tag{4}$$

For a population of M (Kenney and Keeping 1962, p. 181),

$$\mu^{(M)}_{\bar{x}} = \mu \tag{5}$$

$$\sigma^{2(M)} = \frac{\sigma^2}{N}\frac{M-N}{M-1}. \tag{6}$$

Mean-Value Property

Let a function $h : U \to \mathbb{R}$ be continuous on an OPEN SET $U \subseteq \mathbb{C}$. Then h is said to have the ϵ_{z_0}-property if, for each $z_0 \in U$, there exists an $\epsilon_{z_0} > 0$ such that $\bar{D}(z_0,\ \epsilon_{z_0}) \subseteq U$, where $\bar{D}$ is a closed disk, and for every $0 < \epsilon < \epsilon_{z_0}$,

$$h(z_0) = \frac{1}{2\pi}\int_0^{2\pi} h(z_0 + \epsilon e^{i\theta})\, d\theta.$$

If h has the mean-value property, then h is harmonic.

Measurable Function

A function $f : X \to \mathbb{R}$ is measurable if, for every real number a, the set

$$\{x \in X \text{ such that } f(x) > a\}$$

is MEASURABLE. When $X = \mathbb{R}$ with LEBESGUE MEASURE, or more generally any BOREL MEASURE, then all CONTINUOUS functions are measurable. In fact, practically any function that can be described is measurable. Measurable functions are CLOSED under addition and multiplication, but not composition.

The measurable functions form one of the most general classes of REAL FUNCTIONS. They are one of the basic objects of study in ANALYSIS, both because of their wide practical applicability and the aesthetic appeal of their generality. Whether a function $f : X \to \mathbb{R}$ is measurable depends on the MEASURE μ on X, and, in particular, it only depends on the SIGMA ALGEBRA of MEASURABLE SETS in X. Sometimes, the MEASURE on X may be assumed to be a standard measure. For instance, a measurable function on $\mathbb{R}$ is usually measurable with respect to LEBESGUE MEASURE.

From the point of view of MEASURE THEORY, subsets with measure zero do not matter. Often, instead of actual real-valued functions, EQUIVALENCE CLASSES of functions are used. Two functions are equivalent if

the subset of the domain X where they differ has MEASURE ZERO.

See also BOREL MEASURE, LEBESGUE MEASURE, MEASURE, MEASURE SPACE, MEASURE THEORY, REAL FUNCTION, SIGMA ALGEBRA

Measurable Set

If F is a SIGMA ALGEBRA and A is a SUBSET of X, then A is called measurable if A is a member of F. X need not have, a priori, a topological structure. Even if it does, there may be no connection between the open sets in the topology and the given SIGMA ALGEBRA.

See also MEASURABLE SPACE, SIGMA ALGEBRA

Measurable Space

A SET considered together with the SIGMA ALGEBRA on the SET.

See also MEASURABLE SET, MEASURE SPACE, SIGMA ALGEBRA

Measure

The terms "measure," "measurable," etc., have very precise technical definitions (usually involving SIGMA ALGEBRAS) which makes them a little difficult to understand. However, the technical nature of the definitions is extremely important, since it gives a firm footing to concepts which are the basis for much of ANALYSIS (including some of the slippery underpinnings of CALCULUS).

For example, every definition of an INTEGRAL is based on a particular measure: the RIEMANN INTEGRAL is based on JORDAN MEASURE, and the LEBESGUE INTEGRAL is based on LEBESGUE MEASURE. The study of measures and their application to INTEGRATION is known as MEASURE THEORY.

A measure is formally defined as a NONNEGATIVE MAP $m : F \to \mathbb{R}$ (the reals) such that $m(\emptyset) = 0$ and, if A_n is a COUNTABLE SEQUENCE in F and the A_n are pairwise DISJOINT, then

$$m\left(\bigcup_n A_n\right) = \sum_n m(A_n)$$

If, in addition, $m(X) = 1$ for X a MEASURE SPACE, then m is said to be a PROBABILITY MEASURE.

A measure m may also be defined on SETS other than those in the SIGMA ALGEBRA F. By adding to F all sets to which m assigns measure zero, we again obtain a SIGMA ALGEBRA and call this the "completion" of F with respect to m. Thus, the completion of a SIGMA ALGEBRA is the smallest SIGMA ALGEBRA containing F and all sets of measure zero.

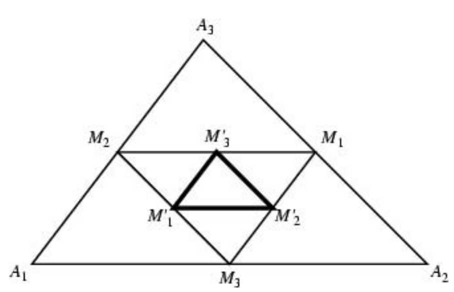
Medial Triangle



The TRIANGLE $\Delta M_1M_2M_3$ formed by joining the MIDPOINTS of the sides of a TRIANGLE $\Delta A_1A_2A_3$. The medial triangle is sometimes also called the AUXILIARY TRIANGLE (Dixon 1991). The medial triangle has TRILINEAR COORDINATES

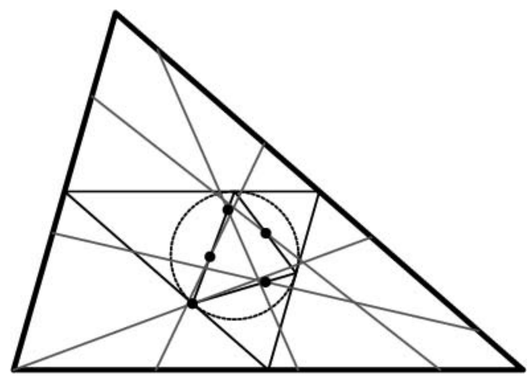
$$A' = 0 : b^{-1} : c^{-1}$$

$$B' = a^{-1} : 0 : c^{-1}$$

$$C' = a^{-1} : b^{-1} : 0.$$

The medial triangle $\Delta M'_1M'_2M'_3$ of the medial triangle $\Delta M_1M_2M_3$ of a TRIANGLE $\Delta A_1A_2A_3$ is similar to $\Delta A_1A_2A_3$.

The INCIRCLE of the medial triangle is called the SPIEKER CIRCLE, and its INCENTER is called the SPIEKER CENTER. The CIRCUMCIRCLE of the medial triangle is called the MEDIAL CIRCLE.



See also ANTICOMPLEMENTARY TRIANGLE, CLEAVANCE CENTER, CLEAVER, SPIEKER CENTER, SPIEKER CIRCLE

Medial Triangle Locus Theorem

Given an original triangle (thick line), find the MEDIAL TRIANGLE (outer thin line) and its INCIRCLE. Take the PEDAL TRIANGLE (inner thin line) of the MEDIAL TRIANGLE with the INCENTER as the PEDAL POINT. Now pick any point on the original triangle, and connect it to the point located a half-PERIMETER away (gray lines). Then the locus of the MIDPOINTS of these lines (the ●s in the above diagram) is the PEDAL TRIANGLE.

Median (Statistics)

The middle value of a distribution (if the sample size N is odd) or average of the two middle items (if N is even), denoted $\mu_{1/2}$ or $\tilde{x}$. For a normal population, the mean μ is the most efficient (in the sense that no other unbiased statistic for estimating μ can have smaller VARIANCE) estimate (Kenney and Keeping 1962, p. 211). The efficiency of the median, measured as the ratio of the variance of the mean to the variance of the median, depends on the sample size $N \equiv 2n + 1$ as

$$\frac{4n}{\pi(2n+)},\tag{1}$$

which tends to the value $2/\pi \approx 0.637$ as N becomes large (Kenney and Keeping 1962, p. 211). Although, the median is less efficient than the MEAN, it is less sensitive to outliers than the MEAN

For large N samples with population median $\tilde{x}_0$,

$$\mu_{\tilde{x}} = \tilde{x}_0 \tag{2}$$

$$\sigma_{\tilde{x}}^2 = \frac{1}{8Nf^2(\tilde{x}_0)}.\tag{3}$$

The median is an L-ESTIMATE (Press *et al.* 1992).

An interesting empirical relationship between the mean, median, and mode which appears to hold for unimodal curves of moderate asymmetry is given by

$$\text{mean} - \text{mode} \approx 3(\text{mean} - \text{median}) \tag{4}$$

(Kenney and Keeping 1962, p. 53), which is the basis for the definition of the PEARSON MODE SKEWNESS.

See also MEAN, MIDRANGE, MODE, ORDER STATISTIC, PEARSON MODE SKEWNESS

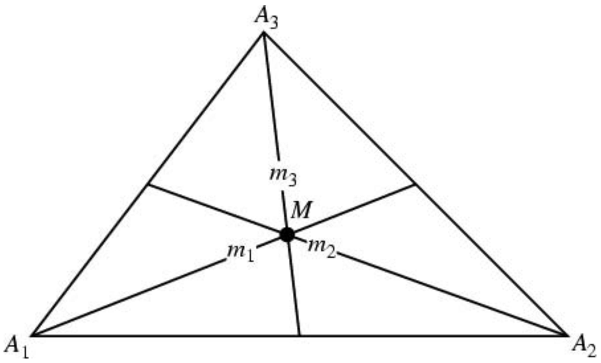
Median (Tetrahedron)



The lines joining the vertices of a TETRAHEDRON to the centroids of the opposite faces are called medians.

See also COMMANDINO'S THEOREM, TETRAHEDRON

References

Altshiller-Court, N. *Modern Pure Solid Geometry.* New York: Chelsea, p. 51, 1979.

Median (Triangle)

The median of a triangle is the CEVIAN from one of its VERTICES to the MIDPOINT of the opposite side. The three medians of any TRIANGLE are CONCURRENT (Casey 1888, p. 3), meeting in the TRIANGLE'S CENTROID (Durell 1928), which has TRILINEAR COORDINATES $1/a : 1/b : 1/c$. In addition, the medians of a TRIANGLE divide one another in the ratio 2:1 (Casey 1888, p. 3). A median also bisects the AREA of a TRIANGLE.

Let m_i denote the length of the median of the ith side a_i. Then

$$m_1^2 = \tfrac{1}{4}(2a_2^2 + 2a_3^2 - a_1^2) \tag{1}$$

$$m_1^2 + m_2^2 + m_3^2 = \tfrac{3}{4}(a_1^2 + a_2^2 + a_3^2) \tag{2}$$

(Casey 1888, p. 23; Johnson 1929, p. 68). The AREA of a TRIANGLE can be expressed in terms of the medians by

$$A = \tfrac{4}{3}\sqrt{s_m(s_m - m_1)(s_m - m_2)(s_m - m_3)},\tag{3}$$

where

$$s_m \equiv \tfrac{1}{2}(m_1 + m_2 + m_3).\tag{4}$$

A median triangle is a TRIANGLE whose sides are equal and PARALLEL to the medians of a given TRIANGLE. The median triangle of the median triangle is similar to the given TRIANGLE in the ratio 3/4.

Median Point

CENTROID (TRIANGLE)

Mediant

Given a FAREY SEQUENCE with consecutive terms h/k and h'/k', then the mediant is defined as the reduced form of the fraction $(h+h')/(k+k')$.

See also FAREY SEQUENCE

Mediating Plane

MEDIATOR

Mediator

The PLANE through the MIDPOINT of a LINE SEGMENT and perpendicular to that segment, also called a mediating plane. The term "mediator" was introduced by J. Neuberg (Altshiller-Court 1979, p. 298).

See also MIDPOINT, PLANE

Meeussen Sequence

A Meeussen sequence is an increasing sequence of positive integers $(m_1, m_2, ...)$ such that $m_1 = 1$, every nonnegative integer is the sum of a subset of the $\{m_i\}$, and each integer $m_i - 1$ is the sum of a unique such subset. Cook and Kleber (2000) show that Meeussen sequences are isomorphic to TOURNAMENT SEQUENCES.

Mega

A LARGE NUMBER defined as

where the CIRCLE NOTATION $\textcircled{n}$ denotes "n in n squares," and triangles and squares are expanded in terms of STEINHAUS-MOSER NOTATION (Steinhaus 1983, pp. 28–9). Here, the typographical error of Steinhaus has been corrected.

Mehler-Dirichlet Integral

$$P_n(\cos\alpha) = \frac{\sqrt{2}}{\pi}\int_0^\alpha \frac{\cos[(n+\tfrac{1}{2})\phi]}{\sqrt{\cos\phi - \cos\alpha}}\,d\phi,$$

where $P_n(x)$ is a LEGENDRE POLYNOMIAL.

Mehler-Fock Transform

The integral transform defined by

$$g(x) = \int_1^\infty t^{1/4-\nu/2}(t-1)^{1/4-\nu/2} P^{\nu-1/2}_{-1/2+ix}(2t-1) f(t)\,dt$$

(Samko *et al.* 1993, p. 761) or

$$g(x) = \int_1^\infty P^k_{-1/2+ix}(t) f(t)\,dt$$

(Samko *et al.* 1993, p. 24), where $P_n(z)$ is a LEGENDRE POLYNOMIAL.

Meijer's G-Function

A very general function which reduces to simpler special functions in many common cases. Meijer's G-function is defined by

$$G_{p,q}^{m,n}\left(x\middle|\begin{matrix}a_1, \ldots, a_p\\ b_1, \ldots, b_p\end{matrix}\right) \equiv$$
$$\frac{1}{2\pi i}\int_{\gamma_L} \frac{\prod_{j=1}^{m}\Gamma(b_j-z)\prod_{j=1}^{n}\Gamma(1-a_j+z)}{\prod_{j=m+1}^{q}\Gamma(1-b_j+z)\prod_{j=n+1}^{q}\Gamma(q_j-z)}\,x^z\,dz, \tag{1}$$

where $\Gamma(z)$ is the GAMMA FUNCTION. The CONTOUR γ_L lies between the POLES of $\Gamma(1-a_i-z)$ and the POLES of $\Gamma(b_i+z)$ (Wolfram 1999, p. 772; Gradshteyn and Ryzhik 2000, pp. 896–03 and 1068–071). Prudnikov *et al.* (1990) contains an extensive nearly 200-page listing of formulas for the Meijer G-function. The function is built into *Mathematica 4.0* as `MeijerG[{{`*a1*, ..., *an*}, {*a(n+1)*, ..., *ap*}}, {{*b1*, ..., *bm*}, {*b(m+1)*, ..., *bq*}}, *z*].

Special cases include

$$G_{12}^{21}\left(z\middle|\begin{matrix}1,1\\1,0\end{matrix}\right)=\ln(z+1) \tag{2}$$

$$G_{12}^{21}\left(z\middle|\begin{matrix}1,1\\1,1\end{matrix}\right)=\frac{z}{z+1} \tag{3}$$

$$G_{10}^{02}\left(\tfrac{1}{2}z|0_{\frac{1}{2}}\right)=\frac{\cos(\sqrt{2z})}{\sqrt{\pi}} \tag{4}$$

$$G_{01}^{10}(z|1-a)=e^{-1/z}z^{-a}. \tag{5}$$

Meijer Transform

The INTEGRAL TRANSFORM

$$(Kf)(x)=\int_{-\infty}^{\infty}\sqrt{xt}K_\nu(xt)f(t)\,dt$$

where $K_\nu(x)$ is a MODIFIED BESSEL FUNCTION OF THE SECOND KIND.

References

Samko, S. G.; Kilbas, A. A.; and Marichev, O. I. *Fractional Integrals and Derivatives.* Yverdon, Switzerland: Gordon and Breach, p. 23, 1993.

Meissel's Formula

A modification of LEGENDRE'S FORMULA for the PRIME COUNTING FUNCTION $\pi(x)$. It starts with

$$\lfloor x \rfloor = 1 + \sum_{1 \leq i \leq a} \left\lfloor \frac{x}{p_i} \right\rfloor - \sum_{1 \leq i \leq j \leq a} \left\lfloor \frac{x}{p_i p_j} \right\rfloor + \sum_{1 \leq i \leq j \leq k \leq a} \left\lfloor \frac{x}{p_i p_j p_k} \right\rfloor - \ldots + \pi(x) - a + P_2(x, a) + P_3(x, a) + \ldots, \quad (1)$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION, $P_2(x, a)$ is the number of INTEGERS $p_i p_j \leq x$ with $a + 1 \leq j \leq j$, and $P_3(x, a)$ is the number of INTEGERS $p_i p_j p_k < x$ with $a + 1 \leq i \leq j \leq k$. Identities satisfied by the Ps include

$$P_2(x, a) = \sum \left[\pi\left(\frac{x}{p_i}\right) - (i - 1) \right] \quad (2)$$

for $p_a < p_i \leq \sqrt{x}$ and

$$P_3(x, a) = \sum_{i>a} P_2\left(\frac{x}{p_i}, a\right) = \sum_{i=a+1}^{c} \sum_{j=i}^{\pi(\sqrt{x/p_i})} \left[\pi\left(\frac{x}{p_i p_j}\right) - (j - 1) \right]. \quad (3)$$

Meissel's formula is

$$\pi(x) = \lfloor x \rfloor - \sum_{i=1}^{c} \left\lfloor \frac{x}{p_i} \right\rfloor + \sum_{1 \leq i \leq j \leq c} \left\lfloor \frac{x}{p_i p_j} \right\rfloor - \ldots + \tfrac{1}{2}(b + c - 2)(b - c + 1) - \sum_{c \leq i \leq b} \pi\left(\frac{x}{p_i}\right), \quad (4)$$

where

$$b \equiv \pi(x^{1/2}) \quad (5)$$

$$c \equiv \pi(x^{1/3}). \quad (6)$$

Taking the derivation one step further yields LEHMER'S FORMULA.

Meixner-Pollaczek Polynomial

The hypergeometric orthogonal polynomial defined by

$$P_n^{(\lambda)}(x; \phi) = \frac{(2\lambda)_n}{n!} e^{in\phi} {}_2F_1(-n, \lambda + ix; 2\lambda; 1 - e^{-2i\phi}),$$

where $(x)_n$ is the POCHHAMMER SYMBOL. The first few are given by

$$P_0^{(\lambda)}(x; \phi) = 1$$

$$P_1^{(\lambda)}(x; \phi) = 2(\lambda \cos \phi + x \sin \phi)$$

$$P_2^{(\lambda)}(x; \phi) = x^2 + \lambda^2 + (\lambda^2 + \lambda - x^2) \cos(2\phi) + (1 + 2\lambda)x \sin(2\phi).$$

References

Meixner Polynomial of the First Kind

Polynomials $m_k(x; \beta, c)$ which form the SHEFFER SEQUENCE for

$$g(t) = \left(\frac{1 - c}{1 - ce^t}\right)^{\beta} \quad (1)$$

$$f(t) = \frac{1 - e^t}{c^{-1} - e^t} \quad (2)$$

and have GENERATING FUNCTION

$$\sum \frac{m_k(x; \beta, c)}{k!} t^k = \left(1 - \frac{t}{c}\right)(1 - t)^{-x-\beta}. \quad (3)$$

The are given in terms of the HYPERGEOMETRIC SERIES by

$$m_n^{(\gamma,\mu)}(x) = (\gamma)_n {}_2F_1(-n, -x; \gamma; 1 - \mu^{-1}), \quad (4)$$

where $(x)_n$ is the POCHHAMMER SYMBOL (Koepf 1998, p. 115). The first few are

$$m_0(x; \beta, c) = 1$$

$$m_1(x; \beta, c) = b + x\left(1 - \frac{1}{c}\right)$$

$$m_2(x; \beta, c) = \frac{b(b + 1)c^2 + (c - 1)(2bc + c + 1)x + (c - 1)^2 x^2}{c^2}.$$

Koekoek and Swarttouw (1998) defined the Meixner polynomials without the POCHHAMMER SYMBOL as

$$M'_n(x;\ \beta,\ c) = {}_2F_1(-n,\ -x;\ \beta;\ 1-1/c). \tag{5}$$

The KRAWTCHOUK POLYNOMIALS are a special case of the Meixner polynomials of the first kind.

Meixner Polynomial of the Second Kind

The polynomials $M_k(x;\ \delta,\ \eta)$ which form the SHEFFER SEQUENCE for

$$g(t) = \{[1+\delta f(t)]^2 + [f(t)]^2\}^{\eta/2} \tag{1}$$

$$f(t) = \tan\left(\frac{t}{1+\delta t}\right) \tag{2}$$

which have GENERATING FUNCTION

$$\sum_{k=0}^{\infty} \frac{M_k(x;\ \delta,\ \eta)}{k!} t^k$$

$$= [(1+\delta t)^2]^{-\eta/2} \exp\left(\frac{x\tan^{-1}t}{1-\delta\tan^{-1}t}\right). \tag{3}$$

The first few are

$$M_0(x;\ \delta,\ \eta) = 1$$
$$M_1(x;\ \delta,\ \eta) = x - \delta\eta$$
$$M_2(x;\ \delta,\ \eta) = x^2 + 2\delta(1-\eta)x + \eta[(\eta+1)\delta^2 - 1].$$

Mellin-Barnes Integral

A type of integral containing gamma functions in their integrands. A typical such integral is given by

$$f(z) = \frac{1}{2\pi i}\int_{\gamma-i\infty}^{\gamma+i\infty} \frac{\Gamma(a_1+A_1 s)\ldots\Gamma(a_n+A_n s)}{\Gamma(c_1+C_1 s)\ldots\Gamma(c_p+C_p s)}$$

$$\times \frac{\Gamma(b_1-B_1 s)\ldots\Gamma(b_n-B_n s)}{\Gamma(d_1-D_1 s)\ldots\Gamma(d_q-D_q s)} z^s\,ds,$$

where γ is real, A_j, B_j, C_j, and D_j are positive, and the CONTOUR is a straight line parallel to the IMAGINARY AXIS with indentations if necessary to avoid poles of the integrand.

Mellin Transform

The INTEGRAL TRANSFORM defined by

$$\phi(z) = \int_0^{\infty} t^{z-1} f(t)\,dt \tag{1}$$

$$f(t) = \frac{1}{2\pi i}\int_{c-i\infty}^{c+i\infty} t^{-z}\phi(z)\,dz. \tag{2}$$

The transform $\phi(z)$ exists if the integral

$$\int_0^\infty |f(x)|x^{k-1}\,dx \qquad (3)$$

is bounded for some $k > 0$, in which case the inverse $f(t)$ exists with $c > k$. The functions $\phi(z)$ and $f(t)$ are called a Mellin transform pair, and either can be computed if the other is known.

The following table gives Mellin transforms of common functions (Bracewell 1999, p. 255). Here, δ is the DELTA FUNCTION, $H(x)$ is the HEAVISIDE STEP FUNCTION, $\Gamma(z)$ is the GAMMA FUNCTION, $B(z;\ a,\ b)$ is the INCOMPLETE BETA FUNCTION, erfc z is the complementary error function ERFC, and Si(z) is the SINE INTEGRAL.

$f(t)$	$\phi(z)$	convergence
$\delta(t-a)$	a^{z-1}	
$H(t-a)$	$-\frac{a^z}{z}$	$a > 0,\ z < 0$
$H(a-t)$	$\frac{a^z}{z}$	$a > 0,\ z > 0$
$t^n H(t-a)$	$-\frac{a^{n+z}}{n+z}$	$a > 0$, $\Re[z+n] < 0$
$t^n H(a-t)$	$\frac{a^{n+z}}{n+z}$	$a > 0$, $\Re[n+z] > 0$
e^{-at}	$a^{-z}\Gamma(z)$	$\Re[a],\ \Re[z] > 0$
e^{-t^2}	$\frac{1}{2}\Gamma\left(\frac{1}{2}z\right)$	$\Re[z] > 0$
$\sin t$	$\Gamma(z)\sin\left(\frac{1}{2}\pi z\right)$	$-1 < \Re[z] < 1$
$\cos t$	$\Gamma(z)\cos\left(\frac{1}{2}\pi z\right)$	$0 < \Re[z] < 1$
$\frac{1}{1+t}$	$\pi\csc(\pi z)$	$0 < \Re[z] < 1$
$\frac{1}{(1+t)^a}$	$\frac{\Gamma(a-z)\Gamma(z)}{\Gamma(a)}$	$\Re[a-z] > 0$, $\Re[z] > 0$
$\frac{1}{1+t^2}$	$\frac{1}{2}\pi\csc\left(\frac{1}{2}\pi z\right)$	$0 < \Re[z] < 2$
$(1-t)^{a-1}H(1-t)$	$\frac{\Gamma(a)\Gamma(z)}{\Gamma(a+z)}$	$\Re[a],\ \Re[z] > 0$
$(t-1)^{-a}H(t-1)$	$\frac{\Gamma(1-a)\Gamma(a-z)}{\Gamma(1-x)}$	$\Re[a-z] > 0$, $\Re[a] < 1$
$\ln(1+t)$	$\frac{\pi\csc(\pi z)}{z}$	$-1 < \Re[z] < 0$
$\frac{1}{2}\pi - \tan^{-1} t$	$\frac{\pi\sec(\frac{1}{2}\pi z)}{2z}$	$0 < \Re[z] < 1$
erfc t	$\frac{\Gamma(\frac{1}{2}(1+z))}{\sqrt{\pi}z}$	$\Re[z] > 0$
Si(t)	$-\frac{1}{z}\Gamma(z)\sin(\frac{1}{2}\pi z)$	$\Re[z] > -1$
$\frac{t^a}{1-t}H(t-a)$	$-B(a^{-1};\ 1-a-z;\ 0)$	$a > 1,\ \Re[a+z] < 1$

Melnikov-Arnold Integral

$$A_m(\lambda) = \int_{-\infty}^{\infty} \cos\left[\tfrac{1}{2}\,m\phi(t) - \lambda t\right]\,dt,$$

where the function

$$\phi(t) \equiv 4\tan^{-1}(e^t) - \pi$$

describes the motion along the pendulum SEPARATRIX. Chirikov (1979) has shown that this integral has the approximate value

$$A_m(\lambda) \approx \begin{cases} \dfrac{4\pi(2\lambda)^{m-1}}{\Gamma(m)}\,e^{-\pi\lambda/2} & \text{for } \lambda > 0 \\ \dfrac{4e^{-\pi|\lambda|/2}}{(2|l|)^{m+1}}\,\Gamma(m+1)\sin(\pi m) & \text{for } \lambda < 0. \end{cases}$$

Melodic Sequence

If a_1, a_2, a_3, ... is an ARTISTIC SEQUENCE, then $1/a_1$, $1/a_2$, $1/a_3$, ... is a melodic sequence. The RECURRENCE RELATION obeyed by melodic series is

$$b_{i+3} = \frac{b_i b_{i+2}^2}{b_{i+1}^2} + \frac{b_{i+2}^2}{b_{i+1}} - b_{i+2}.$$

MEM

MAXIMUM ENTROPY METHOD

Memoryless

A variable x is memoryless with respect to t if, for all s with $t \neq 0$,

$$P(x > s + t | x > t) = P(x > s). \quad (1)$$

Equivalently,

$$\frac{P(x > s + t,\ x > t)}{P(x > t)} = P(x > s) \quad (2)$$

$$P(x > s + t) = P(x > s)P(x > t). \quad (3)$$

The EXPONENTIAL DISTRIBUTION, which satisfies

$$P(x > t) = e^{-\lambda t} \quad (4)$$

$$P(x > s + t) = e^{-\lambda(s+t)}, \quad (5)$$

and therefore

$$P(x > s + t) = P(x > s)P(x > t) = e^{-\lambda s}e^{-\lambda t} = e^{-\lambda(s+t)}, \quad (6)$$

is the only memoryless random distribution.

Ménage Number

MARRIED COUPLES PROBLEM

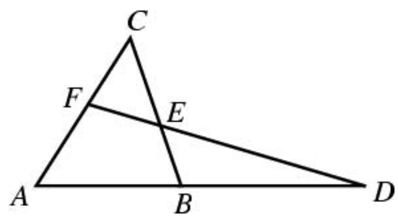
Ménage Problem

MARRIED COUPLES PROBLEM

Menasco's Theorem

For a BRAID with M strands, R components, P positive crossings, and N negative crossings,

$$\begin{cases} P - N \leq U_+ + M - R & \text{if } P \geq N \\ P - N \leq U_- + M - R & \text{if } P \leq N, \end{cases}$$



where $U_\pm$ are the smallest number of positive and negative crossings which must be changed to crossings of the opposite sign. These inequalities imply BENNEQUIN'S CONJECTURE. Menasco's theorem can be extended to arbitrary knot diagrams.

See also BENNEQUIN'S CONJECTURE, BRAID, UNKNOTTING NUMBER

Menelaus' Theorem

For TRIANGLES in the PLANE,

$$AD \cdot BE \cdot CF = BD \cdot CE \cdot AF. \quad (1)$$

For SPHERICAL TRIANGLES,

$$\sin AD \cdot \sin BE \cdot \sin CF = \sin BD \cdot \sin CF \cdot \sin AF \quad (2)$$

This can be generalized to n-gons $P = [V_1, \ldots, V_n]$, where a transversal cuts the side $V_i V_{i+1}$ in W_i for $i = 1, ..., n$, by

$$\prod_{i=1}^{n} \left[\frac{V_i W_i}{W_i V_{i+1}}\right] = (-1)^n. \quad (3)$$

Here, $AD \| CD$ and

$$\left[\frac{AB}{CD}\right] \quad (4)$$

is the ratio of the lengths $[A, B]$ and $[C, D]$ with a PLUS or MINUS SIGN depending if these segments have the same or opposite directions (Grünbaum and Shepard 1995). The case $n = 3$ is PASCH'S AXIOM.

Menger's n-Arc Theorem

Let G be a GRAPH with A and B two disjoint n-tuples of VERTICES. Then either G contains n pairwise disjoint AB-paths, each connecting a point of A and a point of B, or there exists a set of fewer than n VERTICES that separate A and B.

Harary (1994, pp. 47) states the theorem as "the minimum number of points separating two nonadjacent points s and t is the maximum number of disjoint $s-t$ paths." Skiena (1990, p. 178) states the theorem as "a graph is K-CONNECTED GRAPH IFF every pair of vertices is joined by at least k vertex-disjoint paths" (Menger 1927, Whitney 1932).

Menger Sponge

A FRACTAL which is the 3-D analog of the SIERPINSKI CARPET. Let N_n be the number of filled boxes, L_n the length of a side of a hole, and V_n the fractional VOLUME after the nth iteration.

$$N_n = 20^n \tag{1}$$

$$L_n = \left(\tfrac{1}{3}\right)^n = 3^{-n} \tag{2}$$

$$V_n = L_n^3 N_n = \left(\tfrac{20}{27}\right)^n. \tag{3}$$

The CAPACITY DIMENSION is therefore

$$d_{\text{cap}} = -\lim_{n\to\infty} \frac{\ln N_n}{\ln L_n} = -\lim_{n\to\infty} \frac{\ln(20^n)}{\ln(3^{-n})} = \frac{\ln 20}{\ln 3}$$
$$= \frac{\ln(2^5 \cdot 5)}{\ln 3} = \frac{2\ln 2 + \ln 5}{\ln 3} = 2.726833028\ldots \tag{4}$$

J. Mosely is leading an effort to construct a large Menger sponge out of old business cards.

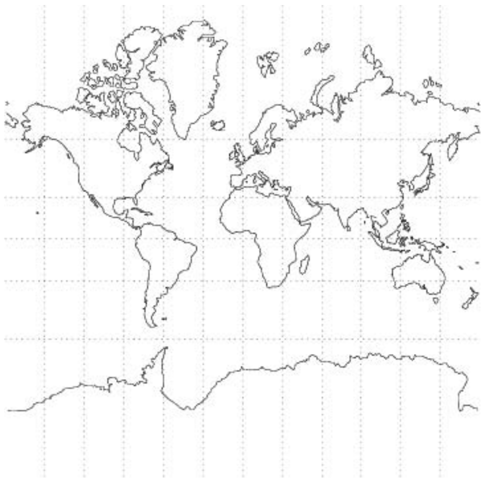
Gray, A. *Modern Differential Geometry of Curves and Surfaces with Mathematica, 2nd ed.* Boca Raton, FL: CRC Press, p. 956, 1997.



Mensuration Formula

A mensuration formula is simply a formula for computing the length-related properties of an object (such as AREA, CIRCUMRADIUS, etc., of a POLYGON) based on other known lengths, areas, etc. Beyer (1987) gives a collection of such formulas for various plane and solid geometric figures.

References

Beyer, W. H. *CRC Standard Mathematical Tables, 28th ed.* Boca Raton, FL: CRC Press, pp. 121–33, 1987.

Mercator Projection

The following equations place the X-AXIS of the projection on the equator and the Y-AXIS at LONGITUDE λ_0, where λ is the LONGITUDE and ϕ is the LATITUDE.

$$x = \lambda - \lambda_0 \tag{1}$$

$$y = \ln[\tan(\tfrac{1}{4}\pi + \tfrac{1}{2}\phi)] \tag{2}$$

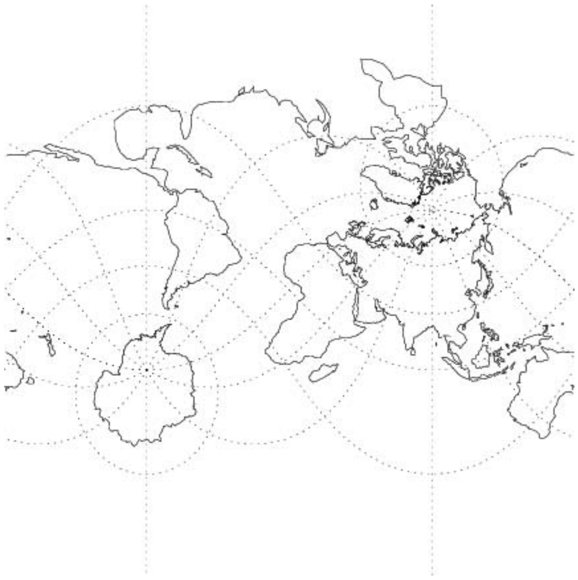
$$= \tfrac{1}{2}\ln\left(\frac{1+\sin\phi}{1-\sin\phi}\right) \tag{3}$$

$$= \sinh^{-1}(\tan\phi) \tag{4}$$

$$= \tanh^{-1}(\sin\phi) \tag{5}$$

$$= \ln(\tan\phi + \sec\phi). \tag{6}$$

The inverse FORMULAS are



$$\phi = 2\tan^{-1}(e^y) - \tfrac{1}{2}\pi \tag{7}$$

$$= \tan^{-1}(\sinh y) \tag{8}$$

$$= \operatorname{gd} y \tag{9}$$

$$\lambda = x + \lambda_0, \tag{10}$$

where $\operatorname{gd} y$ is the GUDERMANNIAN FUNCTION. LOXODROMES are straight lines and GREAT CIRCLES are curved.

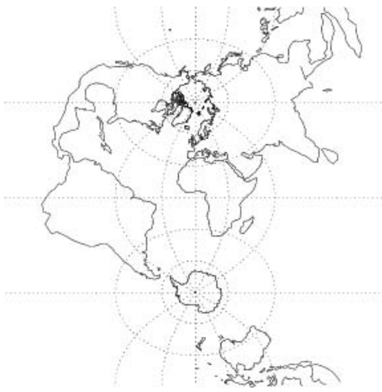
An oblique form of the Mercator projection is illustrated above. It has equations

$$x = \frac{\tan^{-1}[\tan\phi\cos\phi_p + \sin\phi_p\sin(\lambda-\lambda_0)]}{\cos(\lambda-\lambda_0)} \tag{11}$$

$$y = \tfrac{1}{2}\ln\left(\frac{1+A}{1-A}\right) = \tanh^{-1} A, \tag{12}$$

where

$$\lambda_p = \tan^{-1}\left(\frac{\cos\phi_1\sin\phi_2\cos\lambda_1 - \sin\phi_1\cos\phi_2\cos\lambda_2}{\sin\phi_1\cos\phi_2\sin\lambda_2 - \cos\phi_1\sin\phi_2\sin\lambda_1}\right) \tag{13}$$



$$\phi_p = \tan^{-1}\left(-\frac{\cos(\lambda_p - \lambda_1)}{\tan\phi_1}\right) \tag{14}$$

$$A = \sin\phi_p\sin\phi - \cos\phi_p\cos\phi\sin(\lambda-\lambda_0). \tag{15}$$

The inverse FORMULAS are

$$\phi = \sin^{-1}\left(\sin\phi_p\tanh y + \frac{\cos\phi_p\sin x}{\cosh y}\right) \tag{16}$$

$$\lambda = \lambda_0 + \tan^{-1}\left(\frac{\sin\phi_p\sin x - \cos\phi_p\sinh y}{\cos x}\right). \tag{17}$$

There is also a transverse form of the Mercator projection, illustrated above (Deetz and Adams 1934, Snyder 1987). It is given by the equations

$$x = \frac{1}{2} \ln\left(\frac{1+B}{1-B}\right) = \tanh^{-1} B \tag{18}$$

$$y = \tan^{-1}\left[\frac{\tan \phi}{\cos(\lambda - \lambda_0)}\right] - \phi_0 \tag{19}$$

$$\phi = \sin^{-1}\left(\frac{\sin D}{\cosh x}\right) \tag{20}$$

$$\lambda = \lambda_0 + \tan^{-1}\left(\frac{\sinh x}{\cos D}\right), \tag{21}$$

where

$$B \equiv \cos \phi \sin(\lambda - \lambda_0) \tag{22}$$

$$D \equiv y + \phi_0. \tag{23}$$

Finally, the "universal transverse Mercator projection" is a MAP PROJECTION which maps the SPHERE into 60 zones of 6° each, with each zone mapped by a transverse Mercator projection with central MERIDIAN in the center of the zone. The zones extend from 80° S to 84° N (Dana).

Mergelyan's Theorem

Mergelyan's theorem can be stated as follows (Krantz 1999). Let $K \subseteq \mathbb{C}$ be compact and suppose $\mathbb{C}^* \backslash K$ has only finitely many connected components. If $f \in C(K)$ is holomorphic on the interior of K and if $\epsilon > 0$, then there is a RATIONAL FUNCTION $r(z)$ with poles in $\mathbb{C}^* \backslash K$ such that

$$\max_{z \in K} |f(z) - r(z)| < \epsilon. \tag{1}$$

A consequence is that if $P = \{D_1, D_2, \ldots\}$ is an infinite set of disjoint OPEN DISKS D_n of radius r_n such that the union is almost the unit DISK. Then

$$\sum_{n=1}^{\infty} r_n = \infty. \tag{2}$$

Define

$$M_x(P) \equiv \sum_{n=1}^{\infty} r_n^x. \tag{3}$$

Then there is a number $e(P)$ such that $M_x(P)$ diverges for $x < e(P)$ and converges for $x > e(P)$. The above theorem gives

$$1 < e(P) < 2. \quad (4)$$

There exists a constant which improves the inequality, and the best value known is

$$S = 1.306951\ldots. \quad (5)$$

Meromorphic Function

A meromorphic function is a single-valued function that is ANALYTIC in all but possibly a discrete subset of its domain, and at those singularities it must go to infinity like a POLYNOMIAL (i.e., these exceptional points must be POLES and not ESSENTIAL SINGULARITIES). A simpler definition states that a meromorphic function is a function $f(z)$ OF THE FORM

$$f(z) = \frac{g(z)}{h(z)}$$

where $g(z)$ and $h(z)$ are ENTIRE FUNCTIONS with $h(z) \neq 0$ (Krantz 1999, p. 64).

A meromorphic function therefore has only possibly finite, isolated POLES and zeros and no ESSENTIAL SINGULARITIES in its domain. A meromorphic function with an infinite number of poles is exemplified by $\csc(1/z)$ on the PUNCTURED $U = D\backslash\{0\}$, where D is the open unit disk.

An equivalent definition of a meromorphic function is a complex analytic MAP to the RIEMANN SPHERE.

The word derives from the Greek $\mu\varepsilon\rho o\varsigma$ (*meros*), meaning "part," and $\mu o\rho\varphi\eta$ (*morphe*), meaning "form" or "appearance."

Mersenne Number

A number OF THE FORM

$$M_n \equiv 2^n - 1 \quad (1)$$

for n an INTEGER is known as a Mersenne number. The Mersenne numbers are therefore 2-REPDIGITS, and also the numbers obtained by setting $x = 1$ in a FERMAT POLYNOMIAL. The first few are 1, 3, 7, 15, 31, 63, 127, 255, ... (Sloane's A000225).

The number of digits D in the Mersenne number M_n is

$$D = \lfloor \log(2^n - 1) + 1 \rfloor, \quad (2)$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION, which, for large n, gives

$$D \approx \lfloor n \log 2 + 1 \rfloor \approx \lfloor 0.301029n + 1 \rfloor = \lfloor 0.301029n \rfloor + 1. \quad (3)$$

In order for the Mersenne number M_n to be PRIME, n must be PRIME. This is true since for COMPOSITE n with factors r and s, $n = rs$. Therefore, $2^n - 1$ can be written as $2^{rs} - 1$, which is a BINOMIAL NUMBER and can be factored. Since the most interest in Mersenne numbers arises from attempts to factor them, many authors prefer to define a Mersenne number as a number of the above form

$$M_p = 2^p - 1 \quad (4)$$

but with p restricted to PRIME values.

The search for MERSENNE PRIMES is one of the most computationally intensive and actively pursued areas of advanced and distributed computing.

Mersenne Prime

A MERSENNE NUMBER which is PRIME is called a Mersenne prime. In order for the Mersenne number M_n defined by

$$M_n \equiv 2^n - 1$$

for n an INTEGER to be PRIME, n must be PRIME. This is true since for COMPOSITE n with factors r and s, $n = rs$. Therefore, $2^n - 1$ can be written as $2^{rs} - 1$, which is a BINOMIAL NUMBER and can be factored. Every MERSENNE PRIME gives rise to a PERFECT NUMBER. The first few Mersenne primes are 3, 7, 31, 127, 8191, 131071, 524287, 2147483647, ... (Sloane's A000668) corresponding to $n = 2$, 3, 5, 7, 13, 17, 19, 31, 61, 89, ... (Sloane's A000043).

If $n \equiv 3 \pmod 4$ is a PRIME, then $2n+1$ DIVIDES M_n IFF $2n+1$ is PRIME. It is also true that PRIME divisors of $2^p - 1$ must have the form $2kp+1$ where k is a POSITIVE INTEGER and simultaneously of either the form $8n+1$ or $8n-1$ (Uspensky and Heaslet). A PRIME factor p of a Mersenne number $M_q = 2^q - 1$ is a WIEFERICH PRIME IFF $p^2 | 2^q - 1$, Therefore, MERSENNE PRIMES are *not* WIEFERICH PRIMES. All known Mersenne numbers M_p with p PRIME are SQUAREFREE. However, Guy (1994) believes that there are M_p which are not SQUAREFREE.

TRIAL DIVISION is often used to establish the COMPOSITENESS of a potential Mersenne prime. This test immediately shows M_p to be COMPOSITE for $p = 11$, 23, 83, 131, 179, 191, 239, and 251 (with small factors 23, 47, 167, 263, 359, 383, 479, and 503, respectively). A much more powerful primality test for M_p is the LUCAS-LEHMER TEST.

It has been conjectured that there exist an infinite number of Mersenne primes, although finding them is computationally very challenging. The table below gives the index p of known Mersenne primes (Sloane's A000043) M_p, together with the number of digits, discovery years, and discoverer. A similar table has been compiled by C. Caldwell. Note that the region after the 35th known Mersenne prime has not been completely searched, so identification of "the" 36th and larger Mersenne primes are tentative. L. Welsh maintains an extensive bibliography and history of Mersenne numbers. G. Woltman has organized a distributed search program via the Internet in which hundreds of volunteers use their personal computers to perform pieces of the search.

Mertens Conjecture

Given MERTENS FUNCTION defined by

$$M(n) \equiv \sum_{k=1}^{n} \mu(k), \tag{1}$$

where $\mu(n)$ is the MÖBIUS FUNCTION, Mertens (1897) conjecture states that

$$|M(x)| < x^{1/2} \tag{2}$$

for $x>1$. The conjecture has important implications, since the truth of any equality OF THE FORM

$$|M(x)| \leq cx^{1/2} \tag{3}$$

for any fixed c (the form of Mertens conjecture with $c=1$) would imply the RIEMANN HYPOTHESIS. In 1885, Stieltjes claimed that he had a proof that $M(x)x^{-1/2}$ always stayed between two fixed bounds. However, it seems likely that Stieltjes was mistaken.

Mertens conjecture was proved false by Odlyzko and te Riele (1985). Their proof is indirect and does not produce a specific counterexample, but it does show that

$$\limsup_{x\to\infty} M(x)x^{-1/2} > 1.06 \tag{4}$$

$$\liminf_{x\to\infty} M(x)x^{-1/2} < -1.009. \quad (5)$$

Odlyzko and te Riele (1985) believe that there are no counterexamples to Mertens conjecture for $x \leq 10^{20}$, or even 10^{30}. Pintz (1987) subsequently showed that at least one counterexample to the conjecture occurs for $x \leq 10^{65}$, using a weighted integral average of $M(x)/x$ and a discrete sum involving nontrivial zeros of the RIEMANN ZETA FUNCTION.

It is still not known if

$$\limsup_{x\to\infty} |M(x)|x^{-1/2} = \infty, \quad (6)$$

although it seems very probable (Odlyzko and te Riele 1985).

Mertens Constant

N.B. Portions of this entry based on a detailed online essay by S. Finch.

A constant related to the TWIN PRIMES CONSTANT which appears in HARMONIC SERIES for the SUM of reciprocal PRIMES

$$\sum_{p \text{ prime}}^{x} \frac{1}{p} = \ln \ln x + B_1 + o(1), \quad (1)$$

which is given by

$$B_1 = \gamma + \sum_{p \text{ prime}} \left[\ln\left(1-p^{-1}\right) + \frac{1}{p}\right] \approx 0.2614972128, \quad (2)$$

where γ is the EULER-MASCHERONI CONSTANT (Rosser and Schoenfeld 1962; Le Lionnais 1983; Ellison and Ellison 1985; Hardy and Wright 1985). According to Lindqvist and Peetre (1997), this was shown independently by Meissel in 1866 and Mertens (1874). (2) is equivalent to

$$\prod_{p \leq x}\left(1-\frac{1}{p}\right) \sim \frac{e^{-\gamma}}{\ln x}, \quad (3)$$

where γ is the EULER-MASCHERONI CONSTANT (Hardy 1999, p. 57). Knuth (1998) gives 40 digits of B_1, and Gourdon and Sebah give 100 digits. The constant is sometimes known as Kronecker's constant (Schroeder 1997).

A rapidly converging series for B_1 is given by

$$B_1 = \gamma + \sum_{m=2}^{\infty} \frac{\mu(m)}{m} \ln[\zeta(m)], \quad (4)$$

where γ is the EULER-MASCHERONI CONSTANT, $\zeta(n)$ is the RIEMANN ZETA FUNCTION, and $\mu(n)$ is the MÖBIUS FUNCTION (Flajolet and Vardi 1996, Schroeder 1997, Knuth 1998).

The constant B_1 also occurs in the SUMMATORY FUNCTION of the number of DISTINCT PRIME FACTORS $\omega(k)$,

$$\sum_{k=2}^{n} \omega(k) = n \ln \ln n + B_1 n + o(n) \quad (5)$$

(Hardy and Wright 1979, p. 355).

The related constant

$$B_2 = \gamma + \sum_{p \text{ prime}} \left[\ln\left(1-p^{-1}\right) + \frac{1}{p-1}\right] \approx 1.034653 \quad (6)$$

appears in the SUMMATORY FUNCTION of the DIVISOR FUNCTION $\sigma_0(n) = \Omega(n)$,

$$\sum_{k=2}^{n} \Omega(k) = n \ln \ln n + B_2 + o(n) \quad (7)$$

(Hardy and Wright 1979, p. 355).

Another related series is

$$\lim_{n\to\infty}\left(\sum_{k=1}^{\pi(n)} \frac{\ln p_k}{p_k} - \ln n\right) = -\gamma - \sum_{j=2}^{\infty}\sum_{k=1}^{\infty} \frac{\ln p_k}{p_k^j}$$
$$\equiv -C_2 = -1.3325822757\ldots \quad (8)$$

(Rosser and Schoenfeld 1962, Montgomery 1971, Finch).

Mertens Function

The summary function

$$M(n) \equiv \sum_{k=1}^{n} \mu(k), \tag{1}$$

where $\mu(n)$ is the MÖBIUS FUNCTION. The first few values are 1, 0, -1, -1, -2, -1, -2, -2, -2, -1, -2, -2, ... (Sloane's A002321). The first few values of n at which $M(n) = 0$ are 2, 39, 40, 58, 65, 93, 101, 145, 149, 150, ... (Sloane's A028442).

The Mertens function is related to the number of SQUAREFREE integers up to n, which is the sum from 1 to n of the absolute value of $\mu(k)$,

$$\sum_{k=1}^{n} |\mu(k)| \sim \frac{6}{\pi^2}\, n + \mathcal{O}(\sqrt{n}). \tag{2}$$

The Mertens function obeys

$$\sum_{n=1}^{x} M\left(\frac{x}{n}\right) = 1 \tag{3}$$

(Lehman 1960). The analytic form is unsolved, although MERTENS CONJECTURE that

$$|M(x)| < x^{1/2} \tag{4}$$

has been disproved.

Lehman (1960) gives an algorithm for computing $M(x)$ with $\mathcal{O}(x^{2/3+\epsilon})$ operations, while the Lagarias-Odlyzko (1987) algorithm for computing the PRIME COUNTING FUNCTION $\pi(x)$ can be modified to give $M(x)$ in $\mathcal{O}(x^{3/5+\epsilon})$ operations.

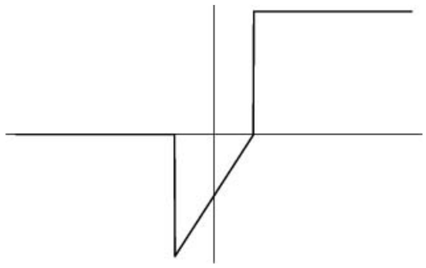
Mertens Theorem

$$\lim_{x\to\infty} \frac{\prod_{\substack{2 \le p \le x \\ p \text{ prime}}} \left(1 - \frac{1}{p}\right)}{\frac{e^{-\gamma}}{\ln x}} = 1,$$



where γ is the EULER-MASCHERONI CONSTANT and $e^{-\gamma} = 0.56145\ldots$.

See also EULER PRODUCT

Mertz Apodization Function

An asymmetrical APODIZATION FUNCTION defined by

$$M(x,\ b,\ d) = \begin{cases} 0 & \text{for } x < -b \\ (x-b)/(2b) & \text{for } -b < x < b \\ 1 & \text{for } b < x < b+2d \\ 0 & \text{for } x < b+2d, \end{cases}$$

where the two-sided portion is $2b$ long (total) and the one-sided portion is $b+2d$ long (Schnopper and Thompson 1974, p. 508). The APPARATUS FUNCTION is

$$M_A(k,\ b,\ d) = \frac{\sin[2\pi k(b\ +\ 2d)]}{2\pi k} + i\left\{\frac{\cos[2\pi k(b\ +\ 2d)]}{2\pi k} - \frac{\sin(2b)}{4\pi^2 k^2 b}\right\}.$$

Mesh Size

When a CLOSED INTERVAL $[a,\ b]$ is partitioned by points $a < x_1 < x_2 < \ldots < x_{n-1} < b$, the lengths of the resulting intervals between the points are denoted Δx_1, Δx_2, ..., Δx_n, and the value max Δx_k is called the mesh size of the partition.

Metalogic

METAMATHEMATICS

Metamathematics

The branch of LOGIC dealing with the study of the combination and application of mathematical symbols, sometimes called METALOGIC. Metamathematics is the study of MATHEMATICS itself, and one of its primary goals is to determine the nature of mathematical reasoning (Hofstadter 1989).

See also LOGIC, MATHEMATICS

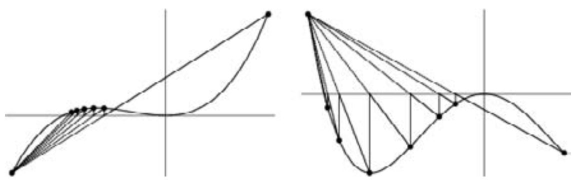
Method of Exclusions

A method used by Gauss to solve the quadratic DIOPHANTINE EQUATION OF THE FORM



$$mx^2+ny^2=A$$

(Dickson 1992, pp. 391 and 407).

References

Dickson, L. E. *History of the Theory of Numbers, Vol. 2: Diophantine Analysis.* New York: Chelsea, p. 407, 1992.

Method of False Position

An ALGORITHM for finding ROOTS which retains that prior estimate for which the function value has opposite sign from the function value at the current best estimate of the root. In this way, the method of false position keeps the root bracketed (Press *et al.* 1992).

Using the two-point form of the line

$$y-y_1=\frac{f(x_{n-1})-f(x_1)}{x_{n-1}-x_1}(x_n-x_1)$$

with $y=0$, using $y_1=f(x_1)$, and solving for x_n therefore gives the iteration

$$x_n=x_1-\frac{x_{n-1}-x_1}{f(x_{n-1})-f(x_1)}f(x_1).$$

Method of Reduction

METHOD OF EXCLUSIONS

Metric

A NONNEGATIVE function $g(x, y)$ describing the "DISTANCE" between neighboring points for a given SET. A metric satisfies the TRIANGLE INEQUALITY

$$g(x, y)+g(y, z)\geq g(x, z) \tag{1}$$

and is SYMMETRIC, so

$$g(x, y)=g(y, x). \tag{2}$$

A metric also satisfies

$$g(x, x)=0. \tag{3}$$

A SET possessing a metric is called a METRIC SPACE. When viewed as a TENSOR, the metric is called a METRIC TENSOR.

Metric Equivalence Problem

1. Find a complete system of invariants, or
2. decide when two METRICS differ only by a coordinate transformation.

The most common statement of the problem is, "Given METRICS g and g', does there exist a coordinate transformation from one to the other?" Christoffel and Lipschitz (1870) showed how to decide this question for two RIEMANNIAN METRICS.

The solution by É. Cartan requires computation of the 10th order COVARIANT DERIVATIVES. The demonstration was simplified by A. Karlhede using the TETRAD formalism so that only seventh order COVARIANT DERIVATIVES need be computed. however, in many common cases, the first or second-order DERIVATIVES are SUFFICIENT to answer the question.

Metric Space

A SET S with a global distance FUNCTION (the METRIC g) which, for every two points x, y in S, gives the DISTANCE between them as a NONNEGATIVE REAL NUMBER $g(x, y)$. A metric space must also satisfy

1. $g(x, y)=0$ IFF $x=y$,
2. $g(x, y)=g(y, x)$,
3. The TRIANGLE INEQUALITY $g(x, y)+g(y, z)\geq g(x, z)$.

See also UNIVERSAL METRIC SPACE

Metric Tensor

A TENSOR, also called a RIEMANNIAN METRIC, which is symmetric and POSITIVE DEFINITE. Very roughly, the metric tensor g_{ij} is a function which tells how to compute the distance between any two points in a given SPACE. Its components can be viewed as multiplication factors which must be placed in front of the differential displacements dx_i in a generalized PYTHAGOREAN THEOREM

$$ds^2=g_{11}\,dx_1^2+g_{12}\,dx_1\,dx_2+g_{22}\,dx_2^2+\ldots. \tag{1}$$

In EUCLIDEAN SPACE, $g_{ij}=\delta_{ij}$ where δ is the KRONECKER DELTA (which is 0 for $i\neq j$ and 1 for $i=j$), reproducing the usual form of the PYTHAGOREAN THEOREM

$$ds^2=dx_1^2+dx_2^2+\ldots. \tag{2}$$

The metric tensor is defined abstractly as an INNER PRODUCT of every TANGENT SPACE of a MANIFOLD such that the INNER PRODUCT is a symmetric, nondegenerate, BILINEAR FORM on a VECTOR SPACE. This means that it takes two VECTORS $\mathbf{v}$, $\mathbf{w}$ as arguments and produces a REAL NUMBER $\langle\mathbf{v}, \mathbf{w}\rangle$ such that

$$\langle k\mathbf{v}, \mathbf{w}\rangle=k\langle\mathbf{v}, \mathbf{w}\rangle=\langle\mathbf{v}, k\mathbf{w}\rangle \tag{3}$$

$$\langle\mathbf{v}+\mathbf{w}, \mathbf{x}\rangle=\langle\mathbf{v}, \mathbf{x}\rangle+\langle\mathbf{w}, \mathbf{x}\rangle \tag{4}$$

$$\langle\mathbf{v}, \mathbf{w}+\mathbf{x}\rangle=\langle\mathbf{v}, \mathbf{w}\rangle+\langle\mathbf{v}, \mathbf{x}\rangle \tag{5}$$

$$\langle\mathbf{v}, \mathbf{w}\rangle=\langle\mathbf{w}, \mathbf{v}\rangle \tag{6}$$

$$\langle \mathbf{v}, \mathbf{v} \rangle \geq 0, \tag{7}$$

with equality IFF $\mathbf{v} = 0$.

In coordinate NOTATION (with respect to the basis),

$$g^{\alpha\beta} = \vec{e}_\alpha \cdot \vec{e}_\beta \tag{8}$$

$$g_{\alpha\beta} = \vec{e}_\alpha \cdot \vec{e}_\beta. \tag{9}$$

$$g_{\mu\nu} \equiv \frac{\partial \xi^\alpha}{\partial x^\mu} \frac{\partial \xi^\beta}{\partial x^\nu} \eta_{\alpha\beta}, \tag{10}$$

where $\eta_{\alpha\beta}$ is the MINKOWSKI METRIC. This can also be written

$$g = D^{\mathrm{T}} \eta D, \tag{11}$$

where

$$D_{\alpha\mu} \equiv \frac{\partial \xi^\alpha}{\partial x^\mu} \tag{12}$$

$$D^{\mathrm{T}}_{\alpha\mu} \equiv D_{\mu\alpha}. \tag{13}$$

$$\frac{\partial}{\partial x^m} g_{il} g^{lk} = \frac{\partial}{\partial x^m} \delta_i^k \tag{14}$$

gives

$$g_{il} \frac{\partial g^{lk}}{\partial x^m} = -g^{lk} \frac{\partial g_{il}}{\partial x^m}. \tag{15}$$

The metric is POSITIVE DEFINITE, so a metric's DISCRIMINANT is POSITIVE. For a metric in 2-space,

$$g \equiv g_{11} g_{22} - g_{12}^2 > 0. \tag{16}$$

The ORTHOGONALITY of CONTRAVARIANT and COVARIANT metrics stipulated by

$$g_{ik} g^{ij} = \delta_k^j \tag{17}$$

for $i = 1, \ldots, n$ gives n linear equations relating the $2n$ quantities g_{ij} and g^{ij}. therefore, if n metrics are known, the others can be determined.

in 2-space,

$$g^{11} = \frac{g_{22}}{g} \tag{18}$$

$$g^{12} = g^{21} = -\frac{g_{12}}{g} \tag{19}$$

$$g^{22} = \frac{g_{11}}{g}. \tag{20}$$

if g is symmetric, then

$$g_{\alpha\beta} = g_{\beta\alpha} \tag{21}$$

$$g^{\alpha\beta} = g^{\beta\alpha}. \tag{22}$$

in EUCLIDEAN SPACE (and all other symmetric SPACES),

$$g_\alpha^\beta = g_\alpha^\beta = \delta_\alpha^\beta, \tag{23}$$

so

$$g_{\alpha\alpha} = \frac{1}{g^{\alpha\alpha}}. \tag{24}$$

The ANGLE ϕ between two parametric curves is given by

$$\cos\phi = \hat{\mathbf{r}}_1 \cdot \hat{\mathbf{r}}_2 = \frac{\mathbf{r}_1}{g_1} \cdot \frac{\mathbf{r}_2}{g_2} = \frac{g_{12}}{g_1 g_2}, \tag{25}$$

so

$$\sin\phi = \frac{\sqrt{g}}{g_1 g_2} \tag{26}$$

and

$$|\mathbf{r}_1 \times \mathbf{r}_2| = g_1 g_2 \sin\phi = \sqrt{g}. \tag{27}$$

The LINE ELEMENT can be written

$$ds^2 = dx_i\, dx_i = g_{ij}\, dq_i\, dq_j \tag{28}$$

where EINSTEIN SUMMATION has been used. But

$$dx_i = \frac{\partial x_i}{\partial q_1} dq_1 + \frac{\partial x_i}{\partial q_2} dq_2 + \frac{\partial x_i}{\partial q_3} dq_3 = \frac{\partial x_i}{\partial q_j} dq_j, \tag{29}$$

so

$$g_{ij} = \sum_k \frac{\partial^2 x_k}{\partial q_i\, \partial q_j}. \tag{30}$$

For ORTHOGONAL coordinate systems, $g_{ij} = 0$ for $i \neq j$, and the LINE ELEMENT becomes (for 3-space)

$$\begin{aligned} ds^2 &= g_{11}\, dq_1^2 + g_{22}\, dq_2^2 + g_{33}\, dq_3^2 \\ &= (h_1\, dq_1)^2 + (h_2\, dq_2)^2 + (h_3\, dq_3)^2, \end{aligned} \tag{31}$$

where $h_i \equiv \sqrt{g_{ii}}$ are called the SCALE FACTORS.

Metropolis Algorithm

SIMULATED ANNEALING

Mex

The MINIMUM excluded value. The mex of a SET S of NONNEGATIVE INTEGERS is the least NONNEGATIVE INTEGER *not* in the set.

See also MEX SEQUENCE

References

Guy, R. K. "Max and Mex Sequences." §E27 in *Unsolved Problems in Number Theory, 2nd ed.* New York: Springer-Verlag, pp. 227–28, 1994.

Mex Sequence

A sequence defined from a FINITE sequence a_0, a_1, ..., a_n by defining $a_{n+1} = \text{mex}_i(a_i + a_{n-i})$, where mex is the MEX (minimum excluded value).

See also MAX SEQUENCE, MEX

References

Guy, R. K. "Max and Mex Sequences." §E27 in *Unsolved Problems in Number Theory, 2nd ed.* New York: Springer-Verlag, pp. 227–28, 1994.

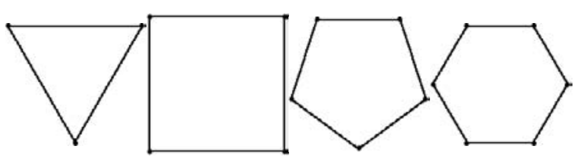
Mian-Chowla Sequence

The sequence produced by starting with $a_1 = 1$ and applying the GREEDY ALGORITHM in the following way: for each $k \geq 2$, let a_k be the least INTEGER exceeding a_{k-1} for which $a_j + a_k$ are all distinct, with $1 \leq j \leq k$. This procedure generates the sequence 1, 2, 4, 8, 13, 21, 31, 45, 66, 81, 97, 123, 148, 182, 204, 252, 290, ... (Sloane's A005282). The RECIPROCAL sum of the sequence,

$$S \equiv \sum_{i=1}^{\infty} \frac{1}{a_i}$$

satisfies

$$2.158435 \leq S \leq 2.158677$$



(R. Lewis).

Mice Problem

n mice start at the corners of a regular n-gon of unit side length, each heading towards its closest neighboring mouse in a counterclockwise direction at constant speed. The mice each trace out a LOGARITHMIC SPIRAL, meet in the center of the POLYGON, and travel a distance

$$d_n = \frac{1}{1 - \cos\left(\frac{2\pi}{n}\right)}.$$

The first few values for $n = 2, 3, ...,$ are

$$\tfrac{1}{2},\ \tfrac{2}{3},\ 1,\ \tfrac{1}{5}\left(5+\sqrt{5}\right),\ 2,\ \frac{1}{1-\cos\left(\frac{2\pi}{7}\right)},$$

$$2+\sqrt{2},\ \frac{1}{1-\cos\left(\frac{2\pi}{9}\right)},\ 3+\sqrt{5},\ \ldots,$$

giving the numerical values 0.5, 0.666667, 1, 1.44721, 2, 2.65597, 3.41421, 4.27432, 5.23607, ... The curve formed by connecting the mice at regular intervals of time is an attractive figure called a WHIRL.

The problem is also variously known as the (three, four, etc.) (bug, dog, etc.) problem. It can be generalized to irregular polygons and mice traveling at differing speeds (Bernhart 1959). Miller (1871) considered three mice in general positions with speeds adjusted to keep paths similar and the triangle similar to the original.

Mid-Arc Points

The mid-arc points M_{AB}, M_{AC}, and M_{BC} of a TRIANGLE ΔABC are the points on the CIRCUMCIRCLE of the triangle which lie half-way along each of the three ARCS determined by the vertices (Johnson 1929). These points arise in the definition of the FUHRMANN CIRCLE and FUHRMANN TRIANGLE, and lie on the extensions of the PERPENDICULAR BISECTORS of the triangle sides drawn from the CIRCUMCENTER O.

Kimberling (1988, 1994) and Kimberling and Veldkamp (1987) define the mid-arc points as the POINTS which have TRIANGLE CENTER FUNCTIONS

$$\alpha_1 = \left[\cos\left(\tfrac{1}{2}B\right) + \cos\left(\tfrac{1}{2}C\right)\right]\sec\left(\tfrac{1}{2}A\right)$$

$$\alpha_2 = \left[\cos\left(\tfrac{1}{2}B\right) + \cos\left(\tfrac{1}{2}C\right)\right]\csc\left(\tfrac{1}{2}A\right).$$

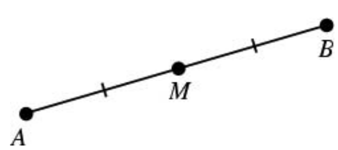
Midcircle

The midcircle of two given CIRCLES is the CIRCLE which would INVERT the circles into each other. Dixon (1991) gives constructions for the midcircle for four of the five possible configurations. In the case of the two given CIRCLES tangent to each other, there are two midcircles.

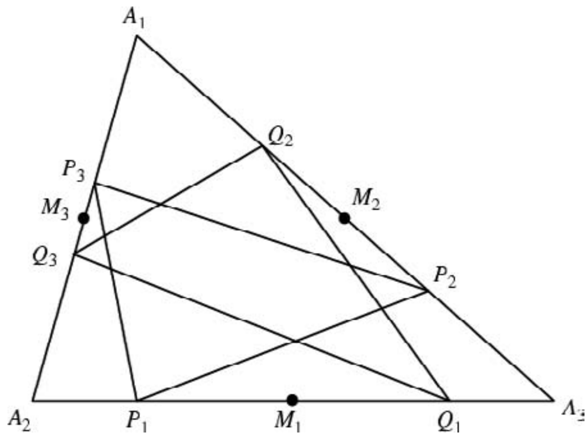
See also INVERSION, INVERSION CIRCLE



References

Dixon, R. *Mathographics.* New York: Dover, pp. 66–8, 1991.

Middlespoint



MITTENPUNKT

Midpoint

The point on a LINE SEGMENT dividing it into two segments of equal length. The midpoint of a line segment is easy to locate by first constructing a LENS using circular arcs, then connecting the cusps of the LENS. The point where the cusp-connecting line intersects the segment is then the midpoint (Pedoe 1995, p. xii). It is more challenging to locate the midpoint using only a COMPASS (i.e., a MASCHERONI CONSTRUCTION).

In a RIGHT TRIANGLE, the midpoint of the HYPOTENUSE is equidistant from the three VERTICES (Dunham 1990).

Given a TRIANGLE $\delta a_1 a_2 a_3$ with AREA δ, locate the midpoints m_i. now inscribe two triangles $\delta p_1 p_2 p_3$ and $\delta q_1 q_2 q_3$ with VERTICES P_i and Q_i placed so that $\overline{P_i M_i} = \overline{Q_i M_i}$. Then $\Delta P_1 P_2 P_3$ and $\Delta Q_1 Q_2 Q_3$ have equal areas

$$\Delta_P = \Delta_Q$$
$$= \Delta\left[1 - \left(\frac{m_1}{a_1} + \frac{m_2}{a_2} + \frac{m_3}{a_3}\right) + \frac{m_2 m_2}{a_2 a_3} + \frac{m_3 m_1}{a_3 a_1} + \frac{m_1 m_2}{a_1 a_2}\right],$$

where a_i are the sides of the original triangle and m_i are the lengths of the MEDIANS (Johnson 1929).

Midpoint Ellipse

The unique ELLIPSE tangent to the MIDPOINTS of a TRIANGLE'S LEGS. The midpoint ellipse has the maximum AREA of any INSCRIBED ELLIPSE (Chakerian 1979). Under an AFFINE TRANSFORMATION, the midpoint ellipse can be transformed into the INCIRCLE of an EQUILATERAL TRIANGLE.

See also AFFINE TRANSFORMATION, ELLIPSE, INCIRCLE, MIDPOINT, TRIANGLE

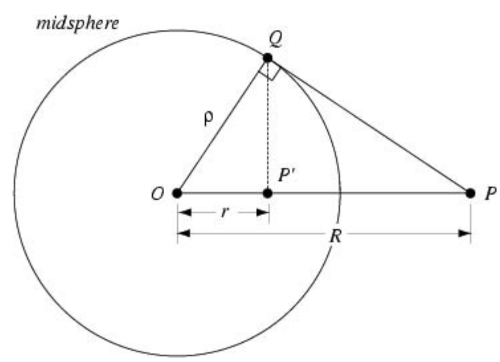
Midpoint Polygon



A DERIVED POLYGON with side ratios chosen as $r = 1/2$ so that inscribed polygons are constructed by connecting the midpoints of the base polygon. For a TRIANGLE P, the midpoint-inscribed polygons P_1, P_2, ... are similar triangles. For a QUADRILATERAL P, the midpoint-inscribed polygon P_1 is a PARALLELOGRAM known as the VARIGNON PARALLELOGRAM, and P_1, P_3, P_5, ... are similar parallelograms, as are P_2, P_4, P_6, ...

See also DERIVED POLYGON, MIDPOINT, VARIGNON PARALLELOGRAM, VARIGNON'S THEOREM

References

Tischel, G. "Ein Konvergenzsatz für Mittenpolygone." *Mitt. Math. Ges. Hamburg* **18**, 169–84, 1999.

Midradius

The RADIUS ρ of the MIDSPHERE of a POLYHEDRON, also called the interradius. Let P be a point on the original polyhedron and P' the corresponding point P on the dual. Then because P and P' are INVERSE POINTS, the radii $r = OP'$, $R = OP$, and $\rho = OQ$ satisfy

$$rR = \rho^2.$$

The above figure shows a plane section of a midsphere.

Let r be the INRADIUS the dual polyhedron, R CIRCUMRADIUS of the original polyhedron, and a the side length of the original polyhedron. (For a PLATONIC SOLID or ARCHIMEDEAN SOLID, r is not only the INRADIUS of the dual polyhedron, but also the INRADIUS of the original polyhedron.) For a REGULAR POLYHEDRON with SCHLÄFLI SYMBOL $\{q, p\}$, the DUAL POLYHEDRON is $\{p, q\}$. Then

$$r^2 = \left[a \csc\left(\frac{\pi}{p}\right)\right]^2 + R^2 = a^2 + \rho^2 \qquad (1)$$

$$\rho^2 = \left[a \cot\left(\frac{\pi}{p}\right)\right]^2 + R^2. \tag{2}$$

Furthermore, let θ be the angle subtended by the edge of an Archimedean solid. Then

$$r = \tfrac{1}{2} a \cos\left(\tfrac{1}{2}\theta\right)\cot\left(\tfrac{1}{2}\theta\right) \tag{3}$$

$$\rho = \tfrac{1}{2} a \cot\left(\tfrac{1}{2}\theta\right) \tag{4}$$

$$R = \tfrac{1}{2} a \csc\left(\tfrac{1}{2}\theta\right), \tag{5}$$

so

$$r : \rho : R = \cos\left(\tfrac{1}{2}\theta\right) : 1 : \sec\left(\tfrac{1}{2}\theta\right) \tag{6}$$

(Cundy and Rollett 1989). Expressing the midradius in terms of the inradius r and circumradius R gives

$$\begin{aligned}\rho &= \tfrac{1}{2}\sqrt{2}\sqrt{r^2 + r\sqrt{r^2 + a^2}} \\ &= \sqrt{R^2 - \tfrac{1}{4}a^2}\end{aligned} \tag{7}$$

for an Archimedean solid.

Midsphere

The sphere with respect to which the vertices of a polyhedron are the poles of the planes of the faces of the dual polyhedron (and vice versa), also called the intersphere, reciprocating sphere, or inversion sphere. The midsphere touches all edges of a semiregular or regular polyhedron, as well as the edges of the dual of that solid (Cundy and Rollett 1989, p. 117). The radius ρ of the midsphere is called the midradius. The figure above shows the Platonic solids and their duals, with the circumsphere of the solid, midsphere, and insphere of the dual superposed.

Miller's Algorithm

For a catastrophically unstable recurrence in one direction, any seed values for consecutive x_j and x_{j+1} will converge to the desired sequence of functions in the opposite direction times an unknown normalization factor.

Miller's Primality Test

If a number fails this test, it is not a PRIME. If the number passes, it *may* be a PRIME. A number passing Miller's test is called a STRONG PSEUDOPRIME to base a. If a number n does not pass the test, then it is called a WITNESS for the COMPOSITENESS of n. If n is an ODD, POSITIVE COMPOSITE NUMBER, then n passes Miller's test for at most $(n-1)/4$ bases with $1 \le a \le$ -1 (Long 1995). There is no analog of CARMICHAEL NUMBERS for STRONG PSEUDOPRIMES.

The only COMPOSITE NUMBER less than 2.5×10^{13} which does not have 2, 3, 5, or 7 as a WITNESS is 3215031751. Miller showed that any composite n has a WITNESS less than $70(\ln n)^2$ if the RIEMANN HYPOTHESIS is true.

Honsberger, R. *Mathematical Gems III.* Washington, DC: Math. Assoc. Amer., pp. 135–37, 1985.

Million

The number $1{,}000{,}000 = 10^6$. While one million in the "American" system of numbers means the same thing as one million in the "British" system, the words BILLION, TRILLION, etc., refer to *different numbers* in the two naming systems. Fortunately, in recent years, the "American" system has become common in both the United States and Britain.

While Americans may say "Thanks a million" to express gratitude, Norwegians offer "Thanks a thousand" ("tusen takk").

See also BILLION, LARGE NUMBER, MILLIARD, THOUSAND, TRILLION

Mills' Constant

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Mills (1947) proved the existence of a constant

$$\theta = 1.3063778838630806904\ldots \quad (1)$$

(Sloane's A051021) such that

$$f(n) = \lfloor \theta^{3^n} \rfloor \quad (2)$$

is PRIME for all $n \ge 1$, where $\lfloor x \rfloor$ is the FLOOR FUNCTION. It is not, however, known if θ is IRRATIONAL. The first few values of $f(n)$ are 2, 11, 1361, 2521008887, ... (Sloane's A051254).

Mills' proof was based on the following theorem by Hoheisel (1930) and Ingham (1937). Let p_n be the nth PRIME, then there exists a constant K such that

$$p_{n+1} - p_n < K p_n^{5/8} \quad (3)$$

for all n. This has more recently been strengthened to

$$p_{n+1} - p_n < K p_n^{1051/1920} \quad (4)$$

(Mozzochi 1986). If the RIEMANN HYPOTHESIS is true, then Cramér (1937) showed that

$$p_{n+1} - p_n = \mathcal{O}\left(\ln p_n \sqrt{p_n}\right) \quad (5)$$

(Finch).

Hardy and Wright (1979) and Ribenboim (1996) point out that, despite the beauty of such PRIME FORMULAS, they do not have any practical consequences. In fact, unless the exact value of θ is known, the PRIMES themselves must be known in advance to determine θ. The numbers generated by $f(n)$ grow very rapidly, with the first few being 2, 11, 1361, ...

A generalization of Mills' theorem to an arbitrary sequence of POSITIVE INTEGERS is given as an exercise

by Ellison and Ellison (1985). Consequently, infinitely many values for θ other than the number $1.3063\ldots$ are possible.

Milnor's Theorem

If a COMPACT MANIFOLD M has NONNEGATIVE RICCI CURVATURE, then its FUNDAMENTAL GROUP has at most POLYNOMIAL growth. On the other hand, if M has NEGATIVE curvature, then its FUNDAMENTAL GROUP has exponential growth in the sense that $n(\lambda)$ grows exponentially, where $n(\lambda)$ is (essentially) the number of different "words" of length λ which can be made in the FUNDAMENTAL GROUP.

Min

MINIMUM

Mincut

Let $G=(V,\ E)$ be a (not necessarily simple) UNDIRECTED edge-weighted graph with nonnegative weights. A cut C of G is any nontrivial subset of V, and the weight of the cut is the sum of weights of edges crossing the cut. A mincut is then defined as a cut of G of minimum weight. The problem is NP-complete for general graphs, but polynomial-time solvable for trees.

See also BOOLEAN FUNCTION, WEIGHTED GRAPH

Minimal Cover

A minimal cover is a COVER for which removal of any single member destroys the covering property. For example, of the five COVERS of {1, 2}, namely {{1}, {2}}, {{1, 2}}, {{1}, {1, 2}}, {{2}, {1, 2}}, and {{1}, {2}, {1, 2}}, only {{1}, {2}} and {{1, 2}} are minimal covers. Similarly, the minimal covers of {1, 2, 3} are given by {{1}, {2}, {3}}, {{1, 2}, {3}}, {{1, 3}, {2}}, {{1, 2}, {2, 3}}, {{1, 2}, {2, 3}}, {{1, 2, 3}}, {{1, 2}, {1, 3}}, {{1, 2}, {2, 3}}. The number of minimal covers of n members for $n = 1$, 2, ..., are 1, 2, 8, 49, 462, 6424, 129425, ... (Sloane's A046165).

Let $\mu(n, k)$ be the number of minimal covers of $\{1, \ldots, n\}$ with k members. Then

$$\mu(n, k) = \frac{1}{k!} \sum_{m=k}^{\alpha_k} \binom{2^k - k - 1}{m - k} m! s(n, m),$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT, $s(n, m)$ is a STIRLING NUMBER OF THE SECOND KIND, and

$$\alpha_k = \min(n, 2^k - 1).$$

Special cases include $\mu(n, 1) = 1$ and $\mu(n, 2) = s(n + 1, 3)$. The table below gives the a triangle of $\mu(n, k)$ (Sloane's A035348).

n	k = 1	k = 2	k = 3	k = 4	k = 5	k = 6	k = 7

Minimal Discriminant

FREY CURVE

Minimal Matrix

A MATRIX with 0 DETERMINANT whose DETERMINANT becomes NONZERO when any element on or below the diagonal is changed from 0 to 1. An example is

$$\mathsf{M} = \begin{bmatrix} 1 & -1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 1 & 1 & 1 & -1 \\ 0 & 0 & 1 & 0 \end{bmatrix}.$$

There are $2^n - 1$ minimal SPECIAL MATRICES of size $n \times n$.

See also SPECIAL MATRIX

References

Knuth, D. E. "Problem 10470." *Amer. Math. Monthly* **102**, 655, 1995.

Minimal Polynomial (Matrix)

The minimal polynomial of a matrix A is the polynomial in A of smallest degree n such that

$$p(\mathsf{A}) = \sum_{i=0}^{n} c_i \mathsf{A}^i = 0. \quad (1)$$

The minimal polynomial divides any polynomial q with $q(\mathsf{A}) = 0$ and, in particular, it divides the CHARACTERISTIC POLYNOMIAL. If the CHARACTERISTIC POLYNOMIAL factors as

$$\operatorname{char}(\mathsf{A})(x) = (x - \lambda_I)^{n_I} \ldots (x - \lambda_k)^{n_k}, \quad (2)$$

then its minimal polynomial is

$$p(x) = (x - \lambda_1)^{m_1} \ldots (x - \lambda_k)^{m_k} \quad (3)$$

with $1 \leq m_i \leq n_i$.

For example, the CHARACTERISTIC POLYNOMIAL of the $n \times n$ ZERO MATRIX is $(-1)^n x^n$, and its minimal polynomial is x. The CHARACTERISTIC POLYNOMIAL and minimal polynomial of

$$\begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} \quad (4)$$

are the same (up to scalar multiple), x^2.

The following *Mathematica* command will find the minimal polynomial for the SQUARE MATRIX a in the variable x.

```
MinPolyMatrix[a_List,x_]:=
```

```
Module[{i,n = 1,qu = {},mnm = {Flatten[IdentityMatrix[Length[a]]]}},
  While[Length[qu] = = 0,
   AppendTo[mnm,Flatten[MatrixPower[a,n]]];
   qu = NullSpace[Transpose[mnm]];
   n++
  ];
  First[qu].Table[x^i,{i,0,n-1}]
 ]
```

Minimal Residue

The value b or $b-m$, whichever is smaller in absolute value, where $a \equiv b \pmod{m}$.

See also Residue (Congruence)

Minimal Set

A set for which the dynamics can be generated by the dynamics on any subset.

Minimal Surface

Minimal surfaces are defined as surfaces with zero mean curvature. A minimal surface parametrized as $\mathbf{x} = (u,\ v,\ h(u,\ v))$ therefore satisfies Lagrange's equation,

$$(1+f_v^2)f_{uu} + 2f_u f_v f_{uv} + (1+f_u^2)f_{vv} = 0.$$

Finding a minimal surface of a boundary with specified constraints is a problem in the calculus of variations and is sometimes known at Plateau's problem. Minimal surfaces may also be characterized as surfaces of minimal surface area for given boundary conditions. A plane is a trivial minimal surface, and the first nontrivial examples (the catenoid and helicoid) were found by Meusnier in 1776 (Meusnier 1785). The problem of finding the minimum bounding surface of a skew quadrilateral was solved by Schwarz (1890).

Note that while a sphere is a "minimal surface" in the sense that it minimizes the surface area-to-volume ratio, it does not qualify as a minimal surface in the sense used by mathematicians.

Euler proved that a minimal surface is planar iff its Gaussian curvature is zero at every point so that it is locally saddle-shaped. The existence of a solution to the general case was independently proven by Douglas (1931) and Radó (1933), although their analysis could not exclude the possibility of singularities. Osserman (1970) and Gulliver (1973) showed that a minimizing solution *cannot* have singularities.

The only known complete (boundaryless), embedded (no self-intersections) minimal surfaces of finite topology known for 200 years were the catenoid, helicoid, and plane. Hoffman discovered a three-ended genus 1 minimal embedded surface, and demonstrated the existence of an infinite number of such surfaces. A four-ended embedded minimal surface has also been found. L. Bers proved that any finite isolated singularity of a single-valued parameterized minimal surface is removable.

A surface can be parameterized using a isothermal parameterization. Such a parameterization is minimal if the coordinate functions x_k are harmonic, i.e., $\phi_k(\zeta)$ are analytic. A minimal surface can therefore be defined by a triple of analytic functions such that $\phi_k \phi_k = 0$. The real parameterization is then obtained as

$$x_k = \Re \int \phi_k(\zeta)\, d\zeta. \tag{1}$$

But, for an analytic function f and a meromorphic function g, the triple of functions

$$\phi_1(\zeta) = f(1-g^2) \tag{2}$$

$$\phi_2(\zeta) = if(1+g^2) \tag{3}$$

$$\phi_3(\zeta) = 2fg \tag{4}$$

are analytic as long as f has a zero of order $\geq m$ at every pole of g of order m. This gives a minimal surface in terms of the Enneper-Weierstrass parameterization

$$\Re \int \begin{bmatrix} f(1-g^2) \\ if(1+g^2) \\ 2fg \end{bmatrix} d\zeta. \tag{5}$$

Minimax Approximation

A minimization of the MAXIMUM error for a fixed number of terms.

See also REMEZ ALGORITHM

Minimax Polynomial

The approximating POLYNOMIAL which has the smallest maximum deviation from the true function. It is closely approximated by the CHEBYSHEV POLYNOMIALS OF THE FIRST KIND.

Minimax Theorem

The fundamental theorem of GAME THEORY which states that every FINITE, ZERO-SUM, two-person GAME has optimal MIXED STRATEGIES. It was proved by John von Neumann in 1928.

Formally, let $\mathbf{X}$ and $\mathbf{Y}$ be MIXED STRATEGIES for players A and B. Let A be the PAYOFF MATRIX. Then

$$\max_X \min_Y \mathbf{X}^T \mathsf{A} \mathbf{Y} = \min_Y \max_X \mathbf{X}^T \mathsf{A} \mathbf{Y} = v,$$

where v is called the VALUE of the GAME and $\mathbf{X}$ and $\mathbf{Y}$ are called the solutions. It also turns out that if there is more than one optimal MIXED STRATEGY, there are infinitely many.

See also GAME, GAME THEORY, MIXED STRATEGY

Willem, M. *Minimax Theorem.* Boston, MA: Birkhäuser, 1996.

Minimize

INFIMUM

Minimum

The smallest value of a set, function, etc. The minimum value of a set of elements $A = \{a_i\}_{i=1}^N$ is denoted min$A$ or $\min_i a_i$, and is equal to the first element of a sorted (i.e., ordered) version of A. For example, given the set $\{3,\ 5,\ 4,\ 1\}$, the sorted version is $\{1,\ 3,\ 4,\ 5\}$, so the minimum is 1. The MAXIMUM and minimum are the simplest ORDER STATISTICS.

A continuous FUNCTION may assume a minimum at a single point or may have minima at a number of points. A GLOBAL MINIMUM of a FUNCTION is the smallest value in the entire RANGE of the FUNCTION, while a LOCAL MINIMUM is the smallest value in some local neighborhood.

For a function $f(x)$ which is CONTINUOUS at a point x_0, a NECESSARY but not SUFFICIENT condition for $f(x)$ to have a RELATIVE MINIMUM at $x = x_0$ is that x_0 be a CRITICAL POINT (i.e., $f(x)$ is either not DIFFERENTIABLE at x_0 or x_0 is a STATIONARY POINT, in which case $f'(x_0) = 0$).

The FIRST DERIVATIVE TEST can be applied to CONTINUOUS FUNCTIONS to distinguish minima from MAXIMA. For twice differentiable functions of one variable, $f(x)$, or of two variables, $f(x,\ y)$, the SECOND DERIVATIVE TEST can sometimes also identify the nature of an EXTREMUM. For a function $f(x)$, the EXTREMUM TEST succeeds under more general conditions than the SECOND DERIVATIVE TEST.

See also CONJUGATE GRADIENT METHOD, CRITICAL POINT, EXTREMUM, FIRST DERIVATIVE TEST, GLOBAL MAXIMUM, INFLECTION POINT, LOCAL MAXIMUM, MAXIMUM, MIDRANGE, ORDER STATISTIC, SADDLE POINT (FUNCTION), SECOND DERIVATIVE TEST, STATIONARY POINT, STEEPEST DESCENT METHOD

Minimum Clique

CLIQUE

Minimum Gossip Graph

GOSSIPING

Minimum Modulus Principle

Let f be ANALYTIC on a DOMAIN $U \subseteq \mathbb{C}$, and assume that f never vanishes. Then if there is a point $z_0 \in U$ such that $|f(z_0)| \leq |f(z)|$ for all $z \in U$, then f is constant.

Let $U \subseteq \mathbb{C}$ be a bounded domain, let f be a continuous function on the closed set $\bar{U}$ that is analytic on U, and assume that f never vanishes on $\bar{U}$. Then the minimum value of $|f|$ on $\bar{U}$ (which always exists) must occur on ∂U. In other words,

$$\min_{\bar{U}} |f| = \min_{\partial U} |f|.$$

Minimum Spanning Tree

The minimum spanning tree of a WEIGHTED GRAPH is a set of $n-1$ edges of minimum total weight which form a SPANNING TREE of the graph. When a graph is unweighted, any SPANNING TREE is a minimum spanning tree.

The minimum spanning tree can be found in polynomial time. Common algorithms include those due to Prinn (1957) and Kruskal (1956). The problem can also be formulated using MATROIDS (Papadimitriou and Steiglitz 1982). The minimum spanning tree can be found using the command `MinimumSpanningTree[g]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``).

See also SPANNING TREE

Minimum Vertex Cover

VERTEX COVER

Minkowski-Bouligand Dimension

In many cases, the HAUSDORFF DIMENSION correctly describes the correction term for a resonator with FRACTAL PERIMETER in Lorentz's conjecture. However, in general, the proper dimension to use turns out to be the Minkowski-Bouligand dimension (Schroeder 1991).

Let $F(r)$ be the AREA traced out by a small CIRCLE with RADIUS r following a fractal curve. Then, providing the LIMIT exists,

$$D_M \equiv \lim_{r\to 0} \frac{\ln F(r)}{-\ln r} + 2$$

(Schroeder 1991). It is conjectured that for all strictly self-similar fractals, the Minkowski-Bouligand dimension is equal to the HAUSDORFF DIMENSION D; otherwise $D_M > D$.

Minkowski Convex Body Theorem

A bounded plane convex region symmetric about a LATTICE POINT and with AREA >4 must contain at least three LATTICE POINTS in the interior. In n-D, the theorem can be generalized to a region with AREA $>2^n$, which must contain at least three LATTICE POINTS. The theorem can be derived from BLICHFELDT'S THEOREM.

MINKOWSKI SPACE

Minkowski-Hlawka Theorem

There exist lattices in n-D having HYPERSPHERE PACKING densities satisfying

$$\eta \geq \frac{\zeta(n)}{2^{n-1}},$$

where $\zeta(n)$ is the RIEMANN ZETA FUNCTION. However, the proof of this theorem is nonconstructive and it is still not known how to actually construct packings that are this dense.

Minkowski Metric

In CARTESIAN COORDINATES,

$$ds^2 = dx^2 + dy^2 + dz^2 \tag{1}$$

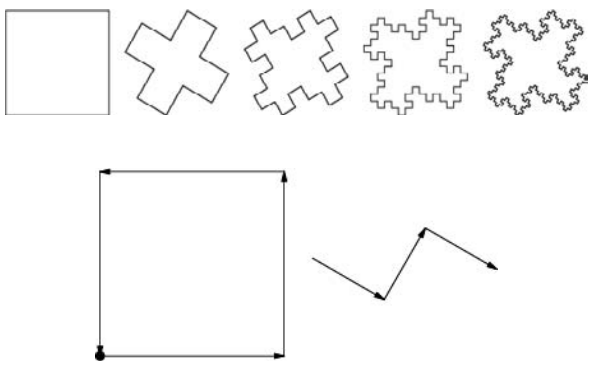
$$dr^2 = -c^2\,dt^2 + dx^2 + dy^2 + dz^2, \tag{2}$$

and

$$g_{\alpha\beta} \equiv \eta_{\alpha\beta} = \begin{bmatrix} -1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}. \tag{3}$$

In SPHERICAL COORDINATES,

$$ds^2 = dr^2 + r^2\,d\theta + r^2 \sin^2\theta\,d\phi^2 \tag{4}$$



$$dr^2 = -c^2\,dt^2 + dr^2 + r^2\,d\theta + r^2 \sin^2\theta\,d\phi^2, \tag{5}$$

and

$$g = \begin{bmatrix} -1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & r^2 & 0 \\ 0 & 0 & 0 & r^2 \sin^2\theta \end{bmatrix}. \quad (6)$$

See also LORENTZ TRANSFORMATION, MINKOWSKI SPACE

Minkowski Sausage

A FRACTAL curve created from the base curve and motif illustrated above (Lauwerier 1991, p. 37). The number of segments after the nth iteration is

$$N_n = 8^n, \quad (1)$$

and

$$\epsilon_n = \left(\frac{1}{4}\right)^n, \quad (2)$$

so the CAPACITY DIMENSION is

$$D \equiv -\lim_{n\to\infty} \frac{\ln N_n}{\ln \epsilon_n} = -\lim_{n\to\infty} \frac{\ln 8^n}{\ln 4^n} = \frac{\ln 8}{\ln 4} = \frac{3 \ln 2}{2 \ln 2} = \frac{3}{2}. \quad (3)$$

The term Minkowski sausage is also used to refer to the MINKOWSKI COVER of a curve.

Minkowski's Inequalities

If $p > 1$, then Minkowski's integral inequality states that

$$\left[\int_a^b |f(x) + g(x)|^p \, dx\right]^{1/p} \leq \left[\int_a^b |f(x)|^p \, dx\right]^{1/p} + \left[\int_a^b |g(x)|^p \, dx\right]^{1/p}.$$

Similarly, if $p > 1$ and $a_k, b_k > 0$, then Minkowski's sum inequality states that

$$\left[\sum_{k=1}^n (a_k + b_k)^p\right]^{1/p} \leq \left(\sum_{k=1}^n a_k^p\right)^{1/p} + \left(\sum_{k=1}^n b_k^p\right)^{1/p}.$$

Equality holds IFF the sequences $a_1, a_2, \ldots$ and $b_1, b_2, \ldots$ are proportional.

Minkowski Space

A 4-D space with the MINKOWSKI METRIC. Alternatively, it can be considered to have a EUCLIDEAN METRIC, but with its VECTORS defined by

$$\begin{bmatrix} x_0 \\ x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} ict \\ x \\ y \\ z \end{bmatrix}, \quad (1)$$

where c is the speed of light and i is the IMAGINARY NUMBER $\sqrt{-1}$. Minkowski space unifies Euclidean 3-space plus time (the "fourth dimension") in Einstein's theory of special relativity.

The METRIC of Minkowski space is DIAGONAL with

$$g_{\alpha\alpha} = \frac{1}{g_{\alpha\alpha}}, \quad (2)$$

so

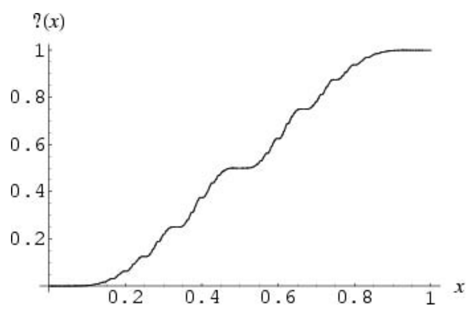
$$\eta^{\beta\delta} = \eta_{\beta\delta}. \quad (3)$$

Let Λ be the TENSOR for a LORENTZ TRANSFORMATION. Then

$$\eta^{\beta\delta} \Lambda^{\gamma}{}_{\delta} = \Lambda^{\beta\gamma} \quad (4)$$

$$\eta_{\alpha\gamma} \Lambda^{\beta\gamma} = \Lambda^{\beta}_{\alpha} \quad (5)$$

$$\Lambda_\alpha^{\ \beta} = \eta_{\alpha\gamma}\Lambda^{\beta\gamma} = \eta_{\alpha\gamma}\eta^{\beta\delta}\Lambda^\gamma{}_\delta. \quad (6)$$



The NECESSARY and SUFFICIENT conditions for a metric $g_{\mu\nu}$ to be equivalent to the Minkowski metric $\eta_{\alpha\beta}$ are that the RIEMANN TENSOR vanishes everywhere ($R^\lambda{}_{\mu\nu\kappa} = 0$) and that at some point $g^{\mu\nu}$ has three POSITIVE and one NEGATIVE EIGENVALUES.

Minkowski's Question Mark Function

The function $y = ?(x)$ defined by Minkowski for the purpose of mapping the rational numbers in the OPEN INTERVAL $(0,\ 1)$ into the QUADRATIC IRRATIONAL NUMBERS of $(0,\ 1)$ in a continuous, order-preserving manner. $?(x)$ takes a number having BINARY expansion $x = 0.a_1a_2a_3\ldots_2$ to the number

$$?(x) = \sum_k \frac{(-1)^{k-1}}{2^{(a_1+\ldots+a_k)-1}}. \quad (1)$$

The function satisfies the following properties (Salem 1943).

1. $?(x)$ is strictly increasing.
2. If x is rational, then $?(x)$ is of the form $k/2^s$, with k and s integers.
3. If x is a QUADRATIC IRRATIONAL NUMBER, then the continued fraction is periodic, and hence $?(x)$ is rational.
4. The function is purely singular (Denjoy 1938).

$?(x)$ can also be constructed as

$$?\left(\frac{p+p'}{q+q'}\right) = \frac{?(p/q) + ?(p'/q')}{2}, \quad (2)$$

where p/q and p'/q' are two consecutive irreducible fractions from the FAREY SEQUENCE. At the nth stage of this definition, $?(x)$ is defined for 2^n+1 values of x, and the ordinates corresponding to these values are $x = k/2^n$ for $k = 0,\ 1,\ \ldots,\ 2^n$ (Salem 1943).

The function satisfies the identity

$$?\left(\frac{1}{k^n}\right) = \frac{1}{2^{k^n-1}}. \quad (3)$$

A few special values include

$$?(0) = 0$$

$$?\left(\tfrac{1}{3}\right) = \tfrac{1}{4}$$

$$?\left(\tfrac{1}{2}\right) = \tfrac{1}{2}$$

$$?(\phi - 1) = \tfrac{2}{3}$$

$$?\left(\tfrac{2}{3}\right) = \tfrac{3}{4}$$

$$?\left(\tfrac{1}{2}\sqrt{2}\right) = \tfrac{4}{5}$$

$$?\left(\tfrac{1}{2}\sqrt{3}\right) = \tfrac{84}{85}$$

$$?(1) = 1,$$

where ϕ is the GOLDEN RATIO.

Minor

The reduced DETERMINANT of a DETERMINANT EXPANSION, denoted M_{ij}, which is formed by omitting the ith row and jth column. The minor can be computed in *Mathematica* using

```
Minor[m_List,{i_Integer,j_Integer}] :=
   Drop[Transpose[Drop[Transpose[m],{j}]],{i}]
```

Minors[m] gives the minors of a matrix m, while Minors[m, k] gives the kth minors of m.

Minor Axis

SEMIMINOR AXIS

Minor Graph

A "minor" is a sort of SUBGRAPH and is what Kuratowski means when he says "contain." It is roughly a small graph which can be mapped into the big one without merging VERTICES.

Minuend

A quantity from which another (the SUBTRAHEND) is subtracted.

See also MINUS, SUBTRACTION, SUBTRAHEND

Minus

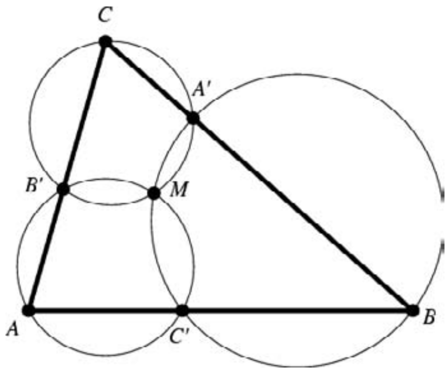
The operation of SUBTRACTION, i.e., a minus b. The operation is denoted $a - b$. The MINUS SIGN "–" is also used to denote a NEGATIVE number, i.e., $-x$.

See also MINUS SIGN, NEGATIVE, PLUS, PLUS OR MINUS, TIMES

Minus or Plus

PLUS OR MINUS

Minus Sign



The symbol "–" which is used to denote a NEGATIVE number or SUBTRACTION.

See also MINUS, PLUS SIGN, SIGN, SUBTRACTION

Minute

ARC MINUTE

Miquel Circles

For a TRIANGLE ΔABC and three points $F(r)$, B', and C', one on each of its sides, the three Miquel circles are the circles passing through each VERTEX and its neighboring side points (i.e., $AC'B'$, $BA'C'$, and $CB'A'$). According to MIQUEL'S THEOREM, the Miquel circles are CONCURRENT in a point M known as the MIQUEL POINT. Similarly, there are n Miquel circles for n lines taken $(n-1)$ at a time.

Miquel Five Circles Theorem

Let five circles with CONCYCLIC centers be drawn such that each intersects its neighbors in two points, with one of these intersections lying itself on the circle of centers. By joining adjacent pairs of the intersection points which do not lie on the circle of center, an (irregular) PENTAGRAM is obtained whose five vertices lie on the circle of centers.

Let the circle of centers have radius r and let the five circles be centered and angular positions θ_i along this circle. The radii r_i of the circles and their angular positions ϕ_i along the circle of centers can then be determined by solving the ten simultaneous equations

$$(\cos\,\phi_i - \cos\,\theta_i)^2 + (\sin\,\phi_i - \sin\,\theta_i)^2 = \frac{r_i^2}{r^2}$$

$$(\cos\,\phi_{i-1} - \cos\,\theta_i)^2 + (\sin\,\phi_{i-1} - \sin\,\theta_i)^2 = \frac{r_i^2}{r^2}$$

for $i = 1, ..., 5$, where $\phi_0 \equiv \phi_5$ and $r_0 \equiv r_5$.

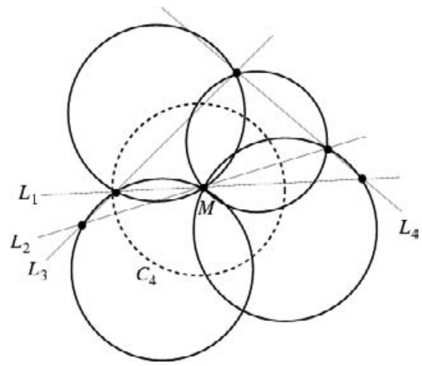
Miquel's Theorem

If points A', B', and C' are marked on each side of a TRIANGLE ΔABC, one on each side (or on a side's extension), then the three MIQUEL CIRCLES (each through a VERTEX and the two marked points on the adjacent sides) are CONCURRENT at a point M called the MIQUEL POINT. This result is a slight generalization of the so-called PIVOT THEOREM.



If M lies in the interior of the triangle, then it satisfies

$$\angle P_2MP_3 = 180° - \alpha_1$$

$$\angle P_3MP_1 = 180° - \alpha_2$$

$$\angle P_1MP_2 = 180° - \alpha_3.$$

The lines from the MIQUEL POINT to the marked points make equal angles with the respective sides. (This is a by-product of the MIQUEL EQUATION.)

A generalized version of Miquel's theorem states that given four lines L_1, ..., L_4 each intersecting the other three, the four MIQUEL CIRCLES passing through each subset of three intersection points of the lines meet in a point known as the 4-Miquel point M. Furthermore, the centers of these four MIQUEL CIRCLES lie on a CIRCLE C_4 (Johnson 1929, p. 139). The lines from M to given points on the sides make equal ANGLES with respect to the sides.

Moreover, given n lines taken by $(n-1)$s yield n MIQUEL CIRCLES like C_4 passing through a point P_n, and their centers lie on a CIRCLE C_{n+1}.

Miquel Triangle

Given a point P and a triangle ΔABC, the Miquel triangle is the triangle $\Delta P_A P_B P_C$ connecting the side points P_A, P_B, and P_C of ΔABC with respect to which M is the MIQUEL POINT. All Miquel triangles of a given point M are directly similar, and M is the SIMILITUDE CENTER in every case.

Mittag-Leffler Function

$$E_n(x) \equiv \sum_{k=0}^{\infty} \frac{x^k}{\Gamma(nk+1)}. \tag{1}$$

It is related to the GENERALIZED HYPERBOLIC FUNCTIONS $F_{n,\,r}^{\alpha}(x)$ by

$$F_{n,\,0}^{1}(x)=E_n(x^n). \tag{2}$$

Special values for integer n are

$$E_0(x)=\frac{1}{1-x} \tag{3}$$

$$E_1(x)=e^x \tag{4}$$

$$E_2(x)=\cosh(\sqrt{x}) \tag{5}$$

$$E_3(x)=\tfrac{1}{3}\left[e^{x^{1/3}}+2e^{-x^{1/3}/2}\cos\left(\tfrac{1}{2}\sqrt{3}x^{1/3}\right)\right] \tag{6}$$

$$E_4(x)=\tfrac{1}{2}\left[\cos(x^{1/4})+\cosh(x^{1/4})\right], \tag{7}$$

and special values of half-integer n are

$$E_{1/2}(x)=e^{x^2}(1+\operatorname{erf} x) \tag{8}$$

$$E_{3/2}(x)=\tfrac{1}{3}\left[e^{x^{2/3}}+2e^{-x^{2/3}/2}\cos\left(\tfrac{1}{2}\sqrt{3}x^{2/3}\right)+\frac{4x\,{}_1F_3\left(1;\tfrac{5}{6},\tfrac{7}{6},\tfrac{3}{2};\tfrac{1}{27}x^2\right)}{\sqrt{\pi}}\right] \tag{9}$$

$$E_{5/2}(x)={}_0F_4\left(;\tfrac{1}{5},\tfrac{2}{5},\tfrac{3}{5},\tfrac{4}{5};\tfrac{1}{3125}x^2\right)+\frac{8x\,{}_1F_5\left(1;\tfrac{7}{10},\tfrac{9}{10},\tfrac{11}{10},\tfrac{13}{10},\tfrac{3}{2};\tfrac{1}{3125}x^2\right)}{15\sqrt{\pi}}, \tag{10}$$

where ${}_pF_q$ are generalized hypergeometric functions, and ${}_0F_q$ is a generalized confluent hypergeometric function. As can be seen, $E_{1/2}(x)$ is closely related to DAWSON'S INTEGRAL $D_(x)$.

The more general Mittag-Leffler function

$$E_{m,n}=\sum_{k=0}^{\infty}\frac{x^k}{\Gamma(mk+n)} \tag{11}$$

can also be defined (Wiman 1905, Agarwal 1953, Gorenflo 1987, Miller 1993, Mainardi and Gorenflo 1995, Gorenflo 1998, Sixdeniers *et al.*).

Mittag-Leffler Polynomial

Polynomials $M_k(x)$ which form the associated SHEFFER SEQUENCE for

$$f(t) = \frac{e^t - 1}{e^t + 1} \tag{1}$$

and have the GENERATING FUNCTION

$$\sum_{k=0}^{\infty} \frac{M_k(x)}{k!} t^k = \left(\frac{1+t}{1-t}\right)^x. \tag{2}$$

An explicit formula is given by

$$M_n(x) = \sum_{k=0}^{n} \binom{n}{k} (n-1)_{n-k} 2^k (x)_k, \tag{3}$$

where $(x)_n$ is a FALLING FACTORIAL, which can be summed in closed form in terms of the HYPERGEOMETRIC FUNCTION, GAMMA FUNCTION, and POLYGAMMA FUNCTION. The binomial identity associated with the SHEFFER SEQUENCE is

$$M_n(x+y) = \sum_{k=0}^{n} \binom{n}{k} M_k(x) M_{n-k}(y). \tag{4}$$

The Mittag-Leffler polynomials satisfy the recurrence formula

$$M_{n+1}(x) = \tfrac{1}{2} x [M_n(x+1) + 2M_n(x) + M_n(x-1)]. \tag{5}$$

The first few Mittag-Leffler polynomials are

$$\begin{aligned} M_0(x) &= 1 \\ M_1(x) &= 2x \\ M_2(x) &= 4x^2 \\ M_3(x) &= 8x^3 + 4x \\ M_4(x) &= 16x^4 + 32x^2. \end{aligned}$$

The Mittag-Leffler polynomials $M_n(x)$ are related to the PIDDUCK POLYNOMIALS by

$$P_n(x) = \tfrac{1}{2}(e^t + 1) M_n(x) \tag{6}$$

(Roman 1984, p. 127).

Mittag-Leffler's Partial Fractions Theorem

Let any finite or infinite set of points having no finite LIMIT POINT be prescribed and associate with each of its points a principal part, i.e., a RATIONAL FUNCTION of the special form

$$h_\nu(z) = \frac{a_{-1}^{(\nu)}}{z - z_\nu} + \frac{a_{-2}^{(\nu)}}{(z - z_\nu)^2} + \ldots + \frac{a_{-\alpha_n u}^{(\nu)}}{(z - z_\nu)^{\alpha_\nu}}$$

for $\nu = 1, 2, \ldots, k$. Then there exists a MEROMORPHIC FUNCTION which has poles with the prescribed principal parts at precisely the prescribed points, and is otherwise regular. It can be represented in the form of a partial fraction decomposition from which one can read off again the poles, along with their principal parts. Further, if $M_0(z)$ is one such function, then

$$M(z) = M_0(z) + G(z)$$

is the most general function satisfying the conditions of the problem, where $G(z)$ denotes an arbitrary ENTIRE FUNCTION.

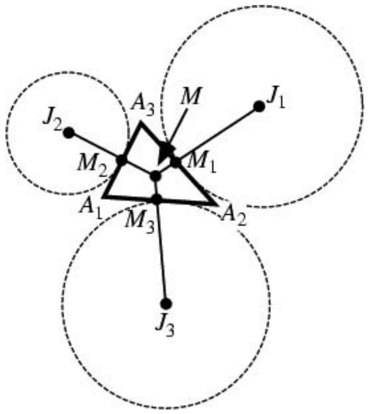
Mittag-Leffler's Theorem

If a function analytic at the origin has no SINGULARITIES other than POLES for finite x, and if we can choose a sequence of contours C_m about $z = 0$ tending to infinity such that $|f(z)|$ never exceeds a given quantity M on any of these contours and $\int |dz/z|$ is uniformly bounded on them, then



$$f(z) = f(0) + \lim [P_m(z) - P_m(0)],$$

where $P_m(z)$ is the sum of the principal parts of $f(z)$ at all POLES α within C_m. If there is a POLE at $z = 0$, then we can replace $f(0)$ by the negative powers and the constant term in the LAURENT SERIES of $f(z)$ about $z = 0$.

Mittenpunkt

The SYMMEDIAN POINT of the EXCENTRAL TRIANGLE, i.e., the point of concurrence M of the lines from the EXCENTERS J_i through the corresponding TRIANGLE side MIDPOINT M_i. It is also called the MIDDLESPOINT and has TRIANGLE CENTER FUNCTION

$$\alpha = b + c - a = \tfrac{1}{2}\cot A.$$

Mixed Fraction

An IMPROPER FRACTION $p/q > 1$ written in the form $n + r/s$. In common usage such as cooking recipes, $n + r/s$ is often written as $n\ \frac{r}{s}$ (e.g., $1\ \frac{1}{2}$), much to the chagrin of mathematicians, to whom $n\ \frac{r}{s}$ means nr/s, *not* $n + r/s$. (The author of this work discovered this fact early in his mathematical career after having points marked off a CALCULUS exam for using the recipe-like notation. Future mathematicians are therefore encouraged to avoid mixed fractions, except perhaps in the kitchen.)

See also FRACTION, IMPROPER FRACTION, PROPER FRACTION

Mixed Indices

MIXED TENSOR

Mixed Partial Derivative

A PARTIAL DERIVATIVE of second or greater order with respect to two or more different variables, for example

$$f_{xy} = \frac{\partial^2 f}{\partial x\, \partial y}.$$

If the mixed partial derivatives exist and are continuous at a point $\mathbf{x}_0$, then they are equal at $\mathbf{x}_0$ regardless of the order in which they are taken.

See also PARTIAL DERIVATIVE

Mixed Strategy

A collection of moves together with a corresponding set of weights which are followed probabilistically in the playing of a GAME. The MINIMAX THEOREM of GAME THEORY states that every finite, zero-sum, two-person game has optimal mixed strategies.

See also GAME THEORY, MINIMAX THEOREM, STRATEGY

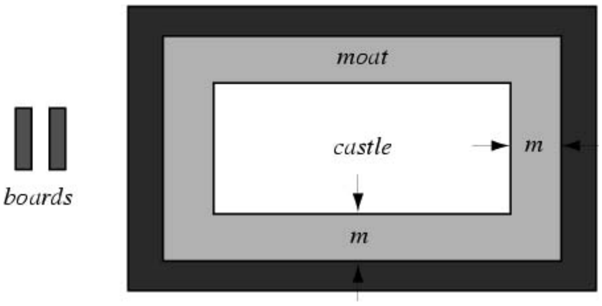
Mixed Tensor

A TENSOR having CONTRAVARIANT and COVARIANT indices.

See also CONTRAVARIANT TENSOR, COVARIANT TENSOR, TENSOR

Mnemonic

A mental device used to aid memorization. Common mnemonics for mathematical constants such as e and PI consist of sentences in which the number of letters in each word give successive digits.



See also e, JOSEPHUS PROBLEM, PI

Moat-Crossing Problem

There are two versions of the moat-crossing problem, one geometric and one algebraic. The geometric moat problems asks for the widest moat Rapunzel can cross

to escape if she has only two unit-length boards (and no means to nail or otherwise attach them together)? More generally, what is the widest moat which can be crossed using n boards? Matthew Cook has conjectured that the asymptotic solution to this problem is $\mathcal{O}(n^{1/3})$ (Finch).

The algebraic moat-crossing problem asks if it is possible to walk to infinity on the REAL LINE using only steps of bounded lengths and steps on the prime numbers. The answer is negative (Gethner *et al.* 1998). However, the Gaussian moat problem that asks whether it is possible to walk to infinity in the GAUSSIAN INTEGERS using the GAUSSIAN PRIMES as stepping stones and taking steps of bounded length is unresolved. Gethner *et al.* (1998) show that a moat of width $\sqrt{26}$ exists.

Moat Problem

MOAT-CROSSING PROBLEM

Möbius Band

MÖBIUS STRIP

Möbius Function

A number theoretic function defined by

$$\mu(n) \equiv \begin{cases} 0 & \text{if } n \text{ has one or repeated prime factors} \\ 1 & \text{if } n = 1 \\ (-1)^k & \text{if } n \text{ is a product of } k \text{ distinct primes,} \end{cases} \tag{1}$$

so $\mu(n) \neq 0$ indicates that n is SQUAREFREE. The first few values are 1, -1, -1, 0, -1, 1, -1, 0, 0, 1, -1, 0, ... (Sloane's A008683). The SUMMATORY FUNCTION of the Möbius function is called MERTENS FUNCTION.
The Möbius function has GENERATING FUNCTIONS

$$\sum_{n=1}^{\infty} \frac{\mu(n)}{n^s} = \frac{1}{\zeta(s)} \tag{2}$$

for $\Re[s] > 1$ (Nagell 1951, p. 130), and

$$\sum_{n=1}^{\infty} \frac{\mu(n) x^n}{1 - x^n} = x \tag{3}$$

for $|x| < 1$. It also obeys the infinite sums

$$\sum_{n=1}^{\infty} \frac{\mu(n)}{n} = 0 \tag{4}$$

$$\sum_{n=1}^{\infty} \frac{\mu(n) \ln n}{n} = -1 \tag{5}$$

and the INFINITE PRODUCT

$$\prod_{n=1}^{\infty} (1 - x^n)^{\mu(n)/n} = e^{-x} \tag{6}$$

for $|x| < 1$ (Bellman 1943; Buck 1944;, Pólya and Szego 1976, p. 126; Robbins 1999). (2) is as "deep" as the PRIME NUMBER THEOREM (Landau 1909, pp. 567–74; Landau 1911; Hardy 1999, p. 24), and behaves asymptotically as

$$\sum_{n \leq x} \mu(n) = \mathcal{O}(x e^{-c\sqrt{\ln x}}) \tag{7}$$

The Möbius function is MULTIPLICATIVE,

$$\mu(mn) = \begin{cases} \mu(m)\mu(n) & \text{if } (m, n) = 1 \\ 0 & \text{if } (m, n) > 1, \end{cases} \tag{8}$$

and satisfies

$$\sum_{d|n} \mu(d) = \delta_{n1}, \tag{9}$$

where δ_{ij} is the KRONECKER DELTA, as well as

$$\sum_{d} \mu(d)\sigma_0\left(\frac{n}{d}\right) = 1, \tag{10}$$

where $\sigma_0(n)$ is the number of divisors (i.e., DIVISOR FUNCTION of order zero; Nagell 1951, p. 281).

Möbius Group

The equation

$$x_1^2 + x_2^2 + \ldots + x_n^2 - 2x_0x_\infty = 0$$

represents an n-D HYPERSPHERE $\mathbb{S}^n$ as a quadratic hypersurface in an $(n+1)$-D real projective space $\mathbb{P}^{n+1}$, where x_a are homogeneous coordinates in $\mathbb{P}^{n+1}$. Then the GROUP $M(n)$ of projective transformations which leave $\mathbb{S}^n$ invariant is called the Möbius group.

See also MODULAR GROUP GAMMA

Möbius Inversion Formula

The transform inverting the sequence

$$g(n) \equiv \sum_{d|n} f(d) \tag{1}$$

into

$$f(n) = \sum_{d|n} \mu(d) g\left(\frac{n}{d}\right), \tag{2}$$

where the sums are over all possible INTEGERS d that DIVIDE n and $\mu(d)$ is the MÖBIUS FUNCTION.

The LOGARITHM of the CYCLOTOMIC POLYNOMIAL

$$\Phi_n(x) = \prod_{d|n} (1 - x^{n/d})^{\mu(d)} \tag{3}$$

is closely related to the Möbius inversion formula.

See also CYCLOTOMIC POLYNOMIAL, MÖBIUS FUNCTION, MÖBIUS TRANSFORM

Möbius Periodic Function

A function periodic with period 2π such that

$$p(\theta + \pi) = -p(\theta)$$

for all θ is said to be Möbius periodic.

See also PERIODIC FUNCTION

Möbius Problem

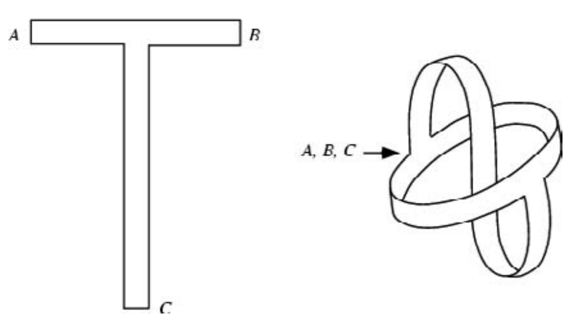
Let $A = \{a_1, a_2, \ldots\}$ be a free Abelian SEMIGROUP, where a_1 is the IDENTITY ELEMENT, and let $\mu(n)$ be the MÖBIUS FUNCTION. Define $\mu(a_n)$ on the elements of the semigroup analogously to the definition of $\mu(n)$ (as $(-1)^r$ if n is the product of r distinct primes) by regarding generators of the semigroup as primes. Then the Möbius problem asks if the properties

1. $a < b$ IMPLIES $ac < bc$ for $a, b, c \in A$, where A has the linear order $a_1 < a_2 < \ldots$,
2. $\mu(a_n) = \mu(n)$ for all n,

imply that

$$a_{m,n} = a_m a_n$$

for all $m, n \geq 1$. Informally, the problem asks "Is the multiplication law on the positive integers uniquely determined by the values of the Möbius function and the property that multiplication respects order?



The problem is known to be true for all $mn \leq 74$ if $\mu(a_n) = \mu(n)$ for all $n \leq 240$ (Flath and Zulauf 1995).

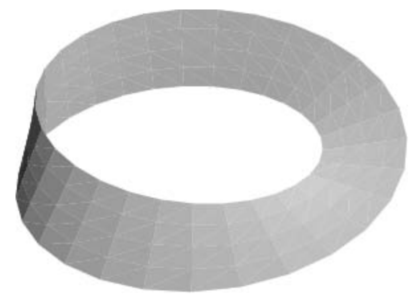
Möbius Shorts



A one-sided surface reminiscent of the MÖBIUS STRIP, attributed to Gourmalin (Bouvier and George 1979, p. 477; Boas 1995). This surface is topologically equivalent to a KLEIN BOTTLE with a hole in it, and is topologically distinct from the MÖBIUS STRIP (Gramain 1984, Stewart 2000b).

See also KLEIN BOTTLE, MÖBIUS STRIP

Möbius Strip

$n \in \mathbb{N}$

A one-sided NONORIENTABLE SURFACE obtained by cutting a closed band into a single strip, giving one of the two ends thus produced a half twist, and then reattaching the two ends. According to Madachy (1979), the B. F. Goodrich Company patented a conveyor belt in the form of a Möbius strip which lasts twice as long as conventional belts.

A Möbius strip of half-width w with midcircle of radius R and at height $z = 0$ can be represented parametrically by

$$x = \left[R + s\cos\left(\tfrac{1}{2}t\right)\right]\cos t \tag{1}$$

$$y = \left[R + s\cos\left(\tfrac{1}{2}t\right)\right]\sin t \tag{2}$$

$$z = s\sin\left(\tfrac{1}{2}t\right), \tag{3}$$

for $s \in [-w, w]$ and $t \in [0, 2\pi]$.

The coefficients of the FIRST FUNDAMENTAL FORM for this surface are

$$E = 1 \tag{4}$$

$$F = 0 \tag{5}$$

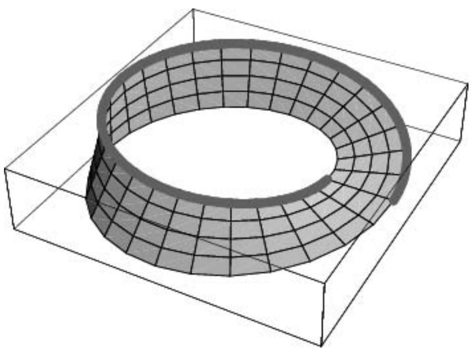
$$G = R^2 + 2Rs\cos\left(\tfrac{1}{2}t\right) + \tfrac{1}{2}s^2(3 + 2\cos t), \tag{6}$$

the SECOND FUNDAMENTAL FORM coefficients are

$$e = 0 \tag{7}$$

$$f = \frac{R}{\sqrt{4R^2 + 3s^2 + 2s\left[4R\cos\left(\frac{1}{2}t\right) + s\cos t\right]}} \tag{8}$$

$$g = \frac{\left[2(R^2 + s^2) + 4Rs\cos\left(\frac{1}{2}t\right) + s^2\cos t\right]\sin\left(\frac{1}{2}t\right)}{\sqrt{4R^2 + 3s^2 + 2s\left[4R\cos\left(\frac{1}{2}t\right) + s\cos t\right]}}, \tag{9}$$



the AREA ELEMENT is

$$dS = \sqrt{R^2 + 2\,Rs\,\cos\left(\tfrac{1}{2}\,t\right) + s^2\left(\tfrac{3}{4} + \tfrac{1}{2}\cos t\right)}\;ds \wedge dt, \quad (10)$$

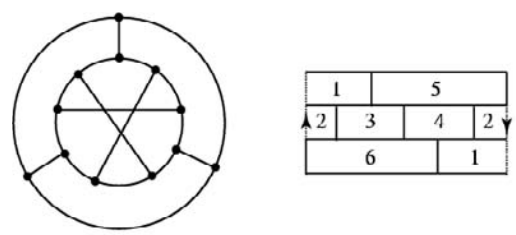
and the GAUSSIAN and MEAN CURVATURES are

$$K = -\frac{4R^2}{\left\{4R^2 + 3s^2 + 2s\left[4\,R\,\cos\left(\tfrac{1}{2}\,t\right) + s\,\cos t\right]\right\}^2} \quad (11)$$

$$H = \frac{2\left[2(R^2 + s^2) + 4\,Rs\,\cos\left(\tfrac{1}{2}\,t\right) + s^2\,\cos t\right]\sin\left(\tfrac{1}{2}\,t\right)}{\left\{4R^2 + 3s^2 + 2s\left[4\,R\,\cos\left(\tfrac{1}{2}\,t\right) + s\,\cos t\right]\right\}^2}. \quad (12)$$

The perimeter of the Möbius strip is given by integrating the complicated function

$$ds = \sqrt{x'^2 + y'^2} = \left[\tfrac{1}{16}\,w^4\,\cos^4\left(\tfrac{1}{2}\,t\right) + \left\{\left[R + w\,\cos(\tfrac{1}{2}\,t)\right]\cos t - \tfrac{1}{2}\,w\,\sin\left(\tfrac{1}{2}\,t\right)\sin t\right\}^4 + \left\{R\,\sin t + \tfrac{1}{4}\,w\left[\sin\left(\tfrac{1}{2}\,t\right) + 3\,\sin\left(\tfrac{3}{2}\,t\right)\right]\right\}^4\right]^{1/2} \quad (13)$$



from 0 to 4π, which can unfortunately not be done in closed form. Note that although the *surface* closes at $t = 2\pi$, this corresponds to the bottom edge connecting with the top edge, as illustrated above, so an additional 2π must be traversed to comprise the entire arc length of the bounding edge.

Cutting a Möbius strip, giving it extra twists, and reconnecting the ends produces unexpected figures called PARADROMIC RINGS (Listing and Tait 1847, Ball and Coxeter 1987) which are summarized in the table below.

half-twists	cuts	divs.	result
1	1	2	1 band, length 2
1	1	3	1 band, length 2
			1 Möbius strip, length 1
1	2	4	2 bands, length 2
1	2	5	2 bands, length 2
			1 Möbius strip, length 1
1	3	6	3 bands, length 2
1	3	7	3 bands, length 2
			1 Möbius strip, length 1
2	1	2	2 bands, length 1
2	2	3	3 bands, length 1
2	3	4	4 bands, length 1

A TORUS can be cut into a Möbius strip with an EVEN number of half-twists, and a KLEIN BOTTLE can be cut in half along its length to make two Möbius strips. In addition, two strips on top of each other, each with a half-twist, give a single strip with four twists when disentangled.

There are three possible SURFACES which can be obtained by sewing a Möbius strip to the edge of a DISK: the BOY SURFACE, CROSS-CAP, and ROMAN SURFACE.

Tietze graph *embedding on the Möbius band*

The Möbius strip has EULER CHARACTERISTIC $\chi = 1$ (or genus $g = 1/2$), so the HEAWOOD CONJECTURE shows that any set of regions on it can be colored using only six colors, as illustrated above.

Möbius Strip Dissection

Tiling of a Möbius strip can be performed immediately by carrying over a tiling of a rectangle with the same two-sided SURFACE AREA. However, additional tilings are possible by cutting tiles across glued edges. An example of such a tiling is the strip constructed from a 5×1 RECTANGLE consisting of two halves of a width 2 square (which are rejoined when edges are connected) separated by a 1×1 square (Stewart 1997). Unfortunately, since the long top and bottom edges must be glued together, this example is not constructible out of paper. It also suffers from having the unit square share a boundary with itself. In 1993, S. J. Chapman found a tiling free of the latter defect (although still suffering from the former) which can be constructed using five squares. No similar tiling is possible using fewer tiles (Stewart 1997).

Möbius Transform

The transformation of a sequence a_1, a_2, ... with

$$a_n = \sum_{d|n} b_d \tag{1}$$

into the sequence b_1, b_2, ... via the MÖBIUS INVERSION FORMULA,

$$b_n = \sum_{d|n} \mu\left(\frac{n}{d}\right) a_d. \tag{2}$$

The transformation of b_n to a_n is sometimes called the sum-of-divisors transform. Two other equivalent formulations are given by

$$\sum_{n=1}^{\infty} a_n x^n = \sum_{n=1}^{\infty} b_n \frac{x^n}{1-x^n}, \tag{3}$$

the right side of which is called a LAMBERT SERIES, and

$$\sum_{n=1}^{\infty} \frac{a_n}{n^s} = \zeta(s) \sum_{n=1}^{\infty} \frac{b_n}{n^2}, \tag{4}$$

where $\zeta(s)$ is the RIEMANN ZETA FUNCTION (Sloane and Plouffe 1995, p. 21).

Example Möbius transformations (Sloane and Plouffe 1995, p. 22) include $b_n = 1$ for all n, giving the inverse transform as $a_n = 1, 2, 2, 3, 2, 4, 2, 4, 3, 4, 2, 6, ...$ (Sloane's A000005), the DIVISOR FUNCTION $\sigma_0(n)$ of n. The Möbius transform of $a_n = n$ gives $b_n = 1, 1, 2, 2, 4, 2, 6, 4, 6, 4, 10, 4, 12, ...$ (Sloane's A000010), the TOTIENT FUNCTION of n. The inverse Möbius transform of the sequence $b_{2n} = 0$ and $b_{2n+1} = 4(-1)^n$ gives $a_n = 4, 4, 0, 4, 8, 0, 0, 4, 4, ...$ (Sloane's A004018), the number of ways $r(n)$ of writing n as a sum of two squares. The inverse Möbius transform of $b_n = 1$ for n prime and $b_n = 0$ for n composite gives the sequence $a_n = 0, 1, 1, 1, 1, 2, 1, 1, 1, ...$ (Sloane's A001221), the number of DISTINCT PRIME FACTORS of n.

Möbius Transformation

Let $a \in \mathbb{C}$ and $|a| < 1$, then

$$\varphi_a(z) = \frac{z - a}{1 - \bar{a}z}$$

is a Möbius transformation, where $\bar{a}$ is the COMPLEX CONJUGATE of a. φ_a is a CONFORMAL TRANSFORMATION SELF-MAP of the UNIT DISK D for each a, and specifically of the boundary of the unit disk to itself. The same holds for $(\varphi_a)^{-1} = \varphi_{-a}$.

Any conformal self-map of the UNIT DISK to itself is a composition of a Möbius transformation with a ROTATION, and any conformal self-map f of the unit disk can be written in the form

$$f(z) = \varphi_b(wz)$$

for some Möbius transformation φ_b and some complex number w with $|w| = 1$ (Krantz 1999, p. 81).

Mock Theta Function

In his last letter to Hardy, Ramanujan defined 17 JACOBI THETA FUNCTION-like functions $F(q)$ with $|q| < 1$ which he called "mock theta functions" (Watson 1936, Ramanujan 1988, pp. 127–31; Ramanujan 2000, pp. 354–55). These functions are Q-SERIES with exponential singularities such that the arguments terminate for some power t^N. In particular, if $f(q)$ is *not* a JACOBI THETA FUNCTION, then it is a mock theta function if, for each ROOT OF UNITY ρ, there is an approximation OF THE FORM

$$f(q) = \sum_{\mu=1}^{M} t^{k_\mu} \exp\left(\sum_{\nu=-1}^{N} c_{\mu\nu} t^\nu\right) + \mathcal{O}(1) \tag{1}$$

as $t \to 0^+$ with $q = \rho e^{-t}$ (Gordon and McIntosh 2000b).

If, in addition, for every ROOT OF UNITY ρ there are modular forms $h_j^{(\rho)}(q)$ and real numbers α_j and $1 \le j \le J(\rho)$ such that

$$f(q) - \sum_{j=1}^{J(\rho)} q^{\alpha_j} h_j^{(\rho)}(q) \tag{2}$$

is bounded as q radially approaches ρ, then $f(q)$ is said to be a strong mock theta function (Gordon and McIntosh 2000b).

Ramanujan found an additional three mock theta functions in his "lost notebook" which were subsequently rediscovered by Watson (1936). The first formula on page 15 of Ramanujan's lost notebook relates the functions which Watson calls $\rho(-q)$ and $\omega(-q)$ (equivalent to the third equation on page 63 of Watson's 1936 paper), and the last formula on page 31 of the lost notebook relates what Watson calls $\nu(-q)$ and $\omega(q^2)$ (equivalent to the fourth equation on page 63 of Watson's paper). The orders of these and Ramanujan's original 17 functions were all 3, 5, or 7.

Ramanujan's "lost notebook" also contained several mock theta functions of orders 6 and 10, which, however, were not explicitly identified as mock theta functions by Ramanujan. Their properties have now been investigated in detail (Andrews and Hickerson 1991, Choi 1999).

Examples of the mock theta functions found by Ramanujan include

$$F_0(q) = \sum_{n=0}^{\infty} \frac{q^{2n^2}}{(q;\ q^2)_n} \tag{3}$$

$$F_1(q) = \sum_{n=1}^{\infty} \frac{q^{2n(n-1)}}{(q;\ q^2)_n}. \tag{4}$$

(Gordon and McIntosh 2000b).

Gordon and McIntosh (2000b) found eight mock theta functions of order 8,

$$S_0(q) = \sum_{n=0}^{\infty} \frac{q^{n^2}(-q;\ q^2)_n}{(-q^2;\ q^2)_n} \tag{5}$$

$$S_1(q) = \sum_{n=0}^{\infty} \frac{q^{n(n+2)}(-q;\ q^2)_n}{(-q^2;\ q^2)_n} \tag{6}$$

$$T_0(q) = \sum_{n=0}^{\infty} \frac{q^{(n+1)(n+2)}(-q^2;\ q^2)_n}{(-q;\ q^2)_{n+1}} \tag{7}$$

$$T_1(q) = \sum_{n=0}^{\infty} \frac{q^{n(n+1)}(-q^2;\ q^2)_n}{(-q;\ q^2)_{n+1}} \tag{8}$$

$$U_0(q)=\sum_{n=0}^{\infty}\frac{q^{n^2}(-q;\ q^2)_n}{(-q^4;\ q^4)_n} \quad (9)$$

$$U_1(q)=\sum_{n=0}^{\infty}\frac{q^{(n+1)^2}(-q;\ q^2)_n}{(-q^2;\ q^4)_{n+1}} \quad (10)$$

$$V_0(q)=-1+2\sum_{n=0}^{\infty}\frac{q^{n^2}(-q;\ q^2)_n}{(q;\ q^2)_n} \quad (11)$$

$$=-1+2\sum_{n=0}^{\infty}\frac{q^{2n^2}(-q^2;\ q^4)_n}{(q;\ q^2)_{2n+1}} \quad (12)$$

$$V_1(q)=\sum_{n=0}^{\infty}\frac{q^{(n+1)^2}(-q;\ q^2)_n}{(q;\ q^4)_{n+1}} \quad (13)$$

$$=\sum_{n=0}^{\infty}\frac{q^{2n^2+2n+1}(-q^4;\ q^4)_n}{(q;\ q^2)_{2n+2}}. \quad (14)$$

Mod

CONGRUENCE

Mode

The most common value obtained in a set of observations. An interesting empirical relationship between the mean, median, and mode which appears to hold for unimodal curves of moderate asymmetry is given by

$$\text{mean} - \text{mode} \approx 3(\text{mean} - \text{median})$$

(Kenney and Keeping 1962, p. 53), which is the basis for the definition of the PEARSON MODE SKEWNESS.

See also MEAN, MEDIAN (STATISTICS), ORDER STATISTIC, PEARSON MODE SKEWNESS

References

Model

A well-formed formula B is said to be true for the interpretation M (written $\models_M B$) IFF every sequence in Σ (the set of all denumerable sequences of elements of the domain of D), satisfies B. B is said to be false for M IFF no sequence in Σ satisfies B.

Then an interpretation M is said to be a model for a set Γ of well-formed formulas IFF every well-formed formula in Γ is true for M (Mendelson 1997, pp. 59–0).

See also GENERALIZED COMPLETENESS THEOREM

References

Mendelson, E. *Introduction to Mathematical Logic, 4th ed.* London: Chapman & Hall, pp. 59–0, 1997.

Model Completion

Model completion is a term employed when EXISTENTIAL CLOSURE is successful. The formation of the COMPLEX NUMBERS, and the move from affine to projective geometry, are successes of this kind. The theory of existential closure gives a theoretical basis of Hilbert's "method of ideal elements."

Mode Locking

A phenomenon in which a system being forced at an IRRATIONAL period undergoes rational, periodic motion which persists for a finite range of forcing values. It may occur for strong couplings between natural and forcing oscillation frequencies.

The phenomenon can be exemplified in the CIRCLE MAP when, after q iterations of the map, the new angle differs from the initial value by a RATIONAL NUMBER

$$\theta_{n+q} = \theta_n + \frac{p}{q}.$$

This is the form of the unperturbed CIRCLE MAP with the WINDING NUMBER

$$\Omega = \frac{p}{q}.$$

For Ω not a RATIONAL NUMBER, the trajectory is QUASIPERIODIC.

See also CHAOS, QUASIPERIODIC FUNCTION

Model Theory

Model theory is a general theory of interpretations of AXIOMATIC SET THEORY. It is the branch of LOGIC studying mathematical structures by considering first-order sentences which are true of those structures and the sets which are definable in those structures by first-order FORMULAS (Marker 1996).

Mathematical structures obeying axioms in a system are called "models" of the system. The usual axioms of ANALYSIS are second order and are known to have the REAL NUMBERS as their unique model. Weakening the axioms to include only the first-order ones leads to a new type of model in what is called NONSTANDARD ANALYSIS.

Modified Bernoulli Number

The numbers b_{2n} having GENERATING FUNCTION

$$\sum_{n=0}^{\infty} b_{2n} x^{2n} = \tfrac{1}{2}\ln\left(\frac{e^{x/2} - e^{-x/2}}{\tfrac{1}{2}x}\right)$$
$$= \tfrac{1}{2}\ln 2 + \tfrac{1}{48}x^2 - \tfrac{1}{5760}x^4 + \tfrac{1}{362880}x^6 - \ldots.$$

For $n = 1, 2, \ldots$, the denominators are 48, 5760, 362880, 19353600, ... (Sloane's A057868).

Modified Bessel Differential Equation

The second-order ordinary differential equation

$$x^2\frac{d^2y}{dx^2} + x\frac{dy}{dx} - (x^2+n^2)y = 0. \quad (1)$$

The solutions are the MODIFIED BESSEL FUNCTIONS OF THE FIRST and SECOND KINDS, and can be written

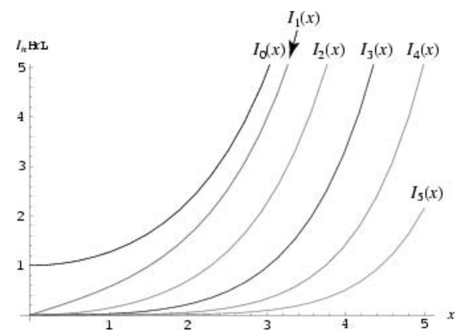
$$y = a_1 J_n(-ix) + a_2 Y_n(-ix) \quad (2)$$
$$= c_1 I_n(x) + c_2 K_n(x), \quad (3)$$

where $J_n(x)$ is a BESSEL FUNCTION OF THE FIRST KIND, $Y_n(x)$ is a BESSEL FUNCTION OF THE SECOND KIND, $I_n(x)$ is a MODIFIED BESSEL FUNCTION OF THE FIRST KIND, and $K_n(x)$ is MODIFIED BESSEL FUNCTION OF THE SECOND KIND.

If $n = 0$, the modified Bessel differential equation becomes

$$x^2\frac{d^2y}{dx^2} + x\frac{dy}{dx} - x^2y = 0, \quad (4)$$

which can also be written



$$\frac{d}{dx}\left(x\frac{dy}{dx}\right) = xy. \quad (5)$$

References

Abramowitz, M. and Stegun, C. A. (Eds.). §9.6.1 in *Handbook of Mathematical Functions with Formulas, Graphs, and Mathematical Tables, 9th printing.* New York: Dover, 1972.

Zwillinger, D. *Handbook of Differential Equations, 3rd ed.* Boston, MA: Academic Press, p. 121, 1997.

Modified Bessel Function of the First Kind

A function $I_n(x)$ which is one of the solutions to the MODIFIED BESSEL DIFFERENTIAL EQUATION and is closely related to the BESSEL FUNCTION OF THE FIRST KIND $J_n(x)$. The above plot shows $I_n(x)$ for $n = 1, 2, \ldots, 5$. In terms of $J_n(x)$,

$$I_n(x) \equiv i^{-n} J_n(ix) = e^{-n\pi i/2} J_n\left(xe^{i\pi/2}\right). \quad (1)$$

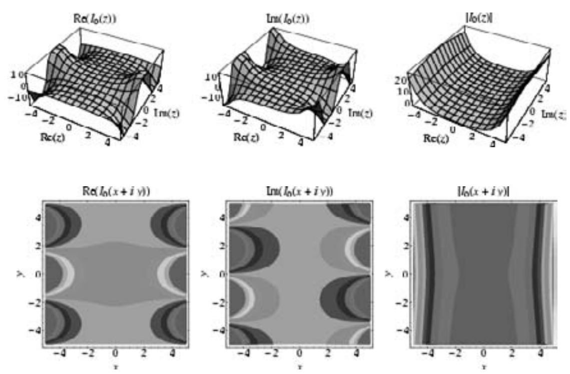
For a REAL NUMBER ν, the function can be computed

using

$$I_\nu(z) = (\tfrac{1}{2}z)^\nu \sum_{k=0}^{\infty} \frac{\left(\frac{1}{4}z^2\right)^k}{k!\Gamma(\nu+k+1)}, \quad (2)$$

where $\Gamma(z)$ is the GAMMA FUNCTION. An integral formula is

$$I_\nu(z) = \frac{1}{\pi}\int_0^\pi e^{z\cos\theta}\cos(\nu\theta)\,d\theta - \frac{\sin(\nu\pi)}{\pi}\int_0^\infty e^{-z\cosh t - \nu t}\,dt, \quad (3)$$



which simplifies for ν an INTEGER n to

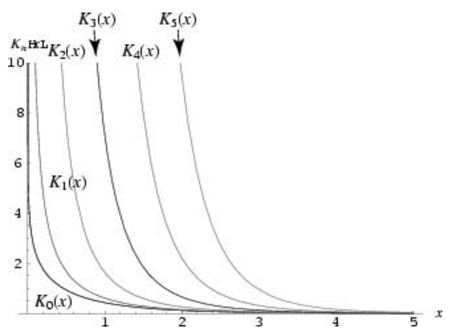
$$I_n(z) = \frac{1}{\pi}\int_0^\pi e^{z\cos\theta}\cos(n\theta)\,d\theta \quad (4)$$

(Abramowitz and Stegun 1972, p. 376).
A derivative identity for expressing higher order modified Bessel functions in terms of $I_0(x)$ is

$$I_n(x) = T_n\left(\frac{d}{dx}\right) I_0(x), \quad (5)$$

where $T_n(x)$ is a CHEBYSHEV POLYNOMIAL OF THE FIRST KIND.

The special case of $n = 0$ gives $I_0(z)$ as the series



$$J_0(z) = \sum_{k=0}^{\infty} \frac{\left(\frac{1}{4}z^2\right)^k}{(k!)^2}. \quad (6)$$

Modified Bessel Function of the Second Kind

The function $K_n(x)$ which is one of the solutions to the MODIFIED BESSEL DIFFERENTIAL EQUATION. The modified Bessel functions of the second kind are sometimes called the Basset functions (Spanier and Oldham 1987, p. 499) or Macdonald functions (Spanier and Oldham 1987, p. 499; Samko *et al.* 1993, p. 20). $K_n(x)$ is closely related to the MODIFIED BESSEL FUNCTION OF THE FIRST KIND $I_n(x)$ and HANKEL FUNCTION $H_n(x)$,

$$K_n(x) \equiv \tfrac{1}{2}\pi i^{n+1} H_n^{(1)}(ix) \quad (1)$$

$$= \tfrac{1}{2}\pi i^{n+1}[J_n(ix) + iN_n(ix)] \quad (2)$$

$$= \frac{\pi}{2}\frac{I_{-n}(x) - I_n(x)}{\sin(n\pi)} \quad (3)$$

(Watson 1966, p. 185). A sum formula for $K_n(x)$ is

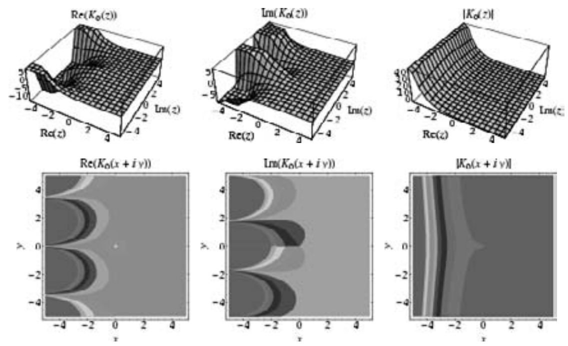
$$K_n(z) = \tfrac{1}{2}(\tfrac{1}{2}z)^{-n}\sum_{k=0}^{n-1}\frac{(n-k-1)!}{k!}(-\tfrac{1}{4}z^2)^k + (-1)^{n+1}\ln(\tfrac{1}{2}z)I_n(z) + (-1)^n\tfrac{1}{2}(\tfrac{1}{2}z)^n \times \sum_{k=0}^{\infty}[\psi(k+1) + \psi(n+k+1)]\frac{(\frac{1}{4}z^2)^k}{k!(n+k)!}, \quad (4)$$

where ψ is the DIGAMMA FUNCTION (Abramowitz and Stegun 1972). An integral formula is

$$K_\nu(z) = \frac{\Gamma(\nu+\frac{1}{2})(2z)^\nu}{\sqrt{\pi}}\int_0^\infty \frac{\cos t\,dt}{(t^2+z^2)^{\nu+1/2}} \quad (5)$$

which, for $\nu = 0$, simplifies to

$$K_0(x)=\int_0^\infty \cos(x \sinh t)\, dt=\int_0^\infty \frac{\cos(xt)\, dt}{\sqrt{t^2+1}}. \quad (6)$$



Other identities are

$$K_n(z)=\frac{\sqrt{\pi}}{(n-\frac{1}{2})!}(\tfrac{1}{2}z)^n \int_1^\infty e^{-zx}(x^2-1)^{n-1/2}\, dx \quad (7)$$

for $n > -1/2$ and

$$K_n(z)=\sqrt{\frac{\pi}{2z}}\frac{e^{-z}}{(n-\frac{1}{2})!}\int_0^\infty e^{-t}t^{n-1/2}\left(1-\frac{t}{2z}\right)^{n-1/2} dt \quad (8)$$

$$=\sqrt{\frac{\pi}{2z}}\frac{e^{-z}}{\left(n-\frac{1}{2}\right)!}\sum_{r=0}^\infty \frac{\left(n-\frac{1}{2}\right)!}{r!\left(n-r-\frac{1}{2}\right)!}(2z)^{-r} \times\int_0^\infty e^{-t}t^{n+r-1/2}\, dt. \quad (9)$$

The special case of $n=0$ gives $K_0(z)$ as the integrals

$$K_0(z)=\int_0^\infty \cos(x \sinh t)\, dt \quad (10)$$

$$=\int_0^\infty \frac{\cos(xt)}{\sqrt{t^2+1}}\, dt \quad (11)$$

(Abramowitz and Stegun 1972, p. 376).

MODULE

Modular Angle

Given a MODULUS k in an ELLIPTIC INTEGRAL, the modular angle is defined by $k \equiv \sin\alpha$. An ELLIPTIC INTEGRAL is written $I(\phi|m)$ when the PARAMETER is used, $I(\phi, k)$ when the MODULUS is used, and $I(\phi\backslash\alpha)$ when the modular angle is used.

See also AMPLITUDE, CHARACTERISTIC (ELLIPTIC INTEGRAL), ELLIPTIC INTEGRAL, HALF-PERIOD RATIO, MODULUS (ELLIPTIC INTEGRAL), NOME, PARAMETER

References

Modular Discriminant

Define $q \equiv e^{2\pi i\tau}$ (cf. the usual NOME), where τ is in the UPPER HALF-PLANE. Then the modular discriminant is defined by

$$\Delta(\tau) \equiv q \prod_{r=1}^{\infty} (1-q^r)^{24}$$

(Rankin 1977, p. 196; Berndt 1988, p. 326; Milne 2000).

If $g_2(\omega_1, \omega_2)$ and $g_3(\omega_1, \omega_2)$ are the INVARIANTS of a WEIERSTRASS ELLIPTIC FUNCTION $\wp(z|\omega_1, \omega_2) = \wp(z; g_2, g_3)$ with periods ω_1 and ω_2, then the discriminant is defined by

$$\Delta(\omega_1, \omega_2) = g_2^3 - 27g_3^2. \tag{1}$$

Letting $\tau \equiv \omega_2/\omega_1$, then

$$\Delta(\tau) \equiv \Delta(1, \tau)$$

$$= \omega_1^{12}\Delta(\omega_1, \omega_2) \tag{2}$$

$$= g_2^3(\tau) - 27g_3^2(\tau). \tag{3}$$

The FOURIER SERIES of $\Delta(\tau)$ for $\tau \in H$, where H is the UPPER HALF-PLANE, is

$$\Delta(\tau) = (2\pi)^{12} \sum_{n=1}^{\infty} \tau(n)e^{2\pi in\tau}, \tag{4}$$

where $\tau(n)$ is the TAU FUNCTION, and $\tau(n)$ are integers (Apostol 1997, p. 20). The discriminant can also be expressed in terms of the DEDEKIND ETA FUNCTION $\eta(\tau)$ by

$$\Delta(\tau) = (2\pi)^{12}[\eta(\tau)]^2 4 \tag{5}$$

(Apostol 1997, p. 51).

Modular Equation

The modular equation of degree n gives an algebraic connection OF THE FORM

$$\frac{K'(l)}{K(l)} = n\frac{K'(k)}{K(k)} \tag{1}$$

between the TRANSCENDENTAL COMPLETE ELLIPTIC INTEGRALS OF THE FIRST KIND with moduli k and l. When k and l satisfy a modular equation, a relationship OF THE FORM

$$\frac{M(l,\ k)\,dy}{\sqrt{(1-y^2)(1-l^2y^2)}} = \frac{dx}{\sqrt{(1-x^2)(1-k^2x^2)}} \tag{2}$$

exists, and M is called the multiplier. In general, if p is an ODD PRIME, then the modular equation is given by

$$\Omega_p(u,\ v) = (v-u_0)(v-u_1)\cdots(v-u_p), \tag{3}$$

where

$$u_p \equiv (-1)^{(p^2-1)/8}[\lambda(q^p)]^{1/8} \equiv (-1)^{(p^2-1)/8}u(q^p), \tag{4}$$

λ is a ELLIPTIC LAMBDA FUNCTION, and

$$q \equiv e^{i\pi t} \tag{5}$$

(Borwein and Borwein 1987, p. 126). An ELLIPTIC INTEGRAL identity gives

$$\frac{K'(k)}{K(k)} = 2\frac{K'\left(\frac{2\sqrt{k}}{1+k}\right)}{K\left(\frac{2\sqrt{k}}{1+k}\right)}, \tag{6}$$

so the modular equation of degree 2 is

$$l = \frac{2\sqrt{k}}{1+k} \tag{7}$$

which can be written as

$$l^2(1+k^2) = 4k. \tag{8}$$

A few low order modular equations written in terms of k and l are

$$\Omega_2 = l^2(1+k)^2 - 4k = 0 \tag{9}$$

$$\Omega_7 = (kl)^{1/4} + (k'l')^{1/4} - 1 = 0 \tag{10}$$

$$\Omega_{23} = (kl)^{1/4} + (k'l')^{1/4} + 2^{2/3}(klk'l')^{1/12} - 1 = 0. \tag{11}$$

In terms of u and v,

$$\Omega_3(u,\ v) = u^4 - v^4 + 2uv(1-u^2v^2) = 0 \tag{12}$$

$$\Omega_5(u,\ v) = v^6 - u^6 + 5u^2v^2(v^2-u^2) + 4uv(u^4v^4-1)$$
$$= \left(\frac{u}{v}\right)^3 + \left(\frac{v}{u}\right)^3 = 2\left(u^2v^2 - \frac{1}{u^2v^2}\right) = 0 \tag{13}$$

$$\Omega_7(u,\ v) = (1-u^8)(1-v^8) - (1-uv)^8 = 0, \tag{14}$$

where

$$u^2 \equiv \sqrt{k} = \frac{\vartheta_2(q)}{\vartheta_3(q)} \tag{15}$$

and

$$v^2 \equiv \sqrt{l} = \frac{\vartheta_2(q^p)}{\vartheta_3(q^p)}. \tag{16}$$

Here, ϑ_i are JACOBI THETA FUNCTIONS.

A modular equation of degree 2^r for $r \geq 2$ can be obtained by iterating the equation for 2^{r-1}. Modular equations for PRIME p from 3 to 23 are given in Borwein and Borwein (1987).

Quadratic modular identities include

$$\frac{\vartheta_3(q)}{\vartheta_3(q^4)} - 1 = \left[\frac{\vartheta_3^2(q^2)}{\vartheta_3^2(q^4)} - 1\right]^{1/2}. \tag{17}$$

Cubic identities include

$$\left[3\frac{\vartheta_2(q^9)}{\vartheta_2(q)} - 1\right]^3 = 9\frac{\vartheta_2^4(q^3)}{\vartheta_2^4(q)} - 1 \tag{18}$$

$$\left[3\frac{\vartheta_3(q^9)}{\vartheta_3(q)} - 1\right]^3 = 9\frac{\vartheta_3^4(q^3)}{\vartheta_3^4(q)} - 1 \tag{19}$$

$$\left[3\frac{\vartheta_4(q^9)}{\vartheta_4(q)} - 1\right]^3 = 9\frac{\vartheta_4^4(q^3)}{\vartheta_4^4(q)} - 1. \tag{20}$$

A seventh-order identity is

$$\sqrt{\vartheta_3(q)\vartheta_3(q^7)} - \sqrt{\vartheta_4(q)\vartheta_4(q^7)} = \sqrt{\vartheta_2(q)\vartheta_2(q^7)}. \tag{21}$$

From Ramanujan (1913–914),

$$(1+q)(1+q^3)(1+q^5)\cdots = 2^{1/6}q^{1/24}(kk')^{-1/12} \tag{22}$$

$$(1-q)(1-q^3)(1-q^5)\cdots = 2^{1/6}q^{1/24}k^{-1/12}k'^{1/6}. \tag{23}$$

When k and l satisfy a MODULAR EQUATION, a relationship OF THE FORM

$$\frac{M(l,\ k)\,dy}{\sqrt{(1-y^2)(1-l^2y^2)}} = \frac{dx}{\sqrt{(1-x^2)(1-k^2x^2)}} \tag{24}$$

exists, and M is called the multiplier. The multiplier of degree n can be given by

$$M_n(l,\ k) \equiv \frac{\vartheta_3^2(q)}{\vartheta_3^2(q^{1/p})} = \frac{K(k)}{K(l)}, \tag{25}$$

where ϑ_i is a JACOBI THETA FUNCTION and $K(k)$ is a complete ELLIPTIC INTEGRAL OF THE FIRST KIND.

The first few multipliers in terms of l and k are

$$M_2(l,\ k) = \frac{1}{1+k} = \frac{1+l'}{2} \tag{26}$$

$$M_3(l,\ k) = \frac{1-\sqrt{\frac{l^3}{k}}}{1-\sqrt{\frac{k^3}{l}}}. \tag{27}$$

In terms of the u and v defined for MODULAR EQUATIONS,

$$M_3 = \frac{v}{v+2u^3} = \frac{2v^3-u}{3u} \tag{28}$$

$$M_5 = \frac{v(1-uv^3)}{v-u^5} = \frac{u+v^5}{5u(1+u^3v)} \tag{29}$$

$$M_7 = \frac{v(1-uv)(1-uv+(uv)^2)]}{v-u^2} = \frac{v^7-u}{7u(1-uv)(1-uv+(uv)^2)]}. \tag{30}$$

Modular Form

A function f is said to be an entire modular form of weight k if it satisfies

1. f is analytic in the UPPER HALF-PLANE H,
2. $f\left(\frac{a\tau+b}{c\tau+d}\right) = (c\tau+d)^k f(\tau)$ whenever $\begin{bmatrix} a & b \\ c & d \end{bmatrix}$ is a member of the MODULAR GROUP GAMMA,
3. The FOURIER SERIES of f has the form

$$f(\tau) = \sum_{n=0}^{\infty} c(n)e^{2\pi in\tau} \tag{1}$$

Care must be taken when consulting the literature because some authors use the term "dimension $-k$" or "degree $-k$" instead of "weight k," and others write k instead of k (Apostol 1997, pp. 114–15). More general types of modular forms (which are not "entire"rpar; can also be defined which allow poles in H or at $i\infty$. Since KLEIN'S ABSOLUTE INVARIANT J, which is a MODULAR FUNCTION, has a pole at $i\infty$, it is a nonentire modular form of weight 0.

The set of all entire forms of weight k is denoted M_k, which is a linear space over the complex field. The dimension of M_k is 1 for $k = 4$, 6, 8, 10, and 14 (Apostol 1997, p. 119).

$c(0)$ is the value of f at $i\infty$, and if $c(0) = 0$, the function is called a CUSP FORM. The smallest r such that $c(r) \neq 0$ is called the order of the zero of f at $i\infty$. An estimate for $c(n)$ states that

$$c(n) = \mathcal{O}(n^{2k-1}) \tag{2}$$

if $f \in M_{2k}$ and is not a CUSP FORM (Apostol 1997, p. 135).

If $f \neq 0$ is an entire modular form of weight k, let f have N zeros in the closure of the FUNDAMENTAL REGION R_Γ (omitting the vertices). Then

$$k = 12N + 6N(i) + 4N(\rho) + 12N(i\infty), \tag{3}$$

where $N(p)$ is the order of the zero at a point p (Apostol 1997, p. 115). In addition,

1. The only entire modular forms of weight $k = 0$ are the constant functions.
2. If k is ODD, $k < 0$, or $k = 2$, then the only entire modular form of weight k is the zero function.
3. Every nonconstant entire modular form for weight $k \geq 4$, where k is EVEN.
4. The only entire CUSP FORM of weight $k < 12$ is the zero function.

(Apostol 1997, p. 116).

For f an entire modular form of EVEN weight $k \geq 0$, define $E_0(\tau) = 1$ for all τ. Then f can be expressed in exactly one way as a sum

$$f = \sum_{\substack{r=0 \\ k=12r\neq 2}}^{\lfloor k/12 \rfloor} a_r E_{k-12r}\Delta^r, \tag{4}$$

where a_r are complex numbers, E_n is an EISENSTEIN SERIES, and Δ is the MODULAR DISCRIMINANT of the WEIERSTRASS ELLIPTIC FUNCTION. CUSP FORMS of EVEN weight k are then those sums for which $a_0 = 0$ (Apostol 1997, pp. 117–18). Even more amazingly, every entire modular form f of weight k is a POLYNOMIAL in E_4 and E_6 given by

$$f = \sum_{a,\ b} c_{a,\ b} E_4^a E_6^a, \tag{5}$$

where the $c_{a,\ b}$ are complex numbers and the sum is extended over all integers $a,\ b \geq 0$ such that $4a + 6b = k$ (Apostol 1998, p. 118).

Modular forms satisfy rather spectacular and special properties resulting from their surprising array of internal symmetries. Hecke discovered an amazing connection between each modular form and a corresponding DIRICHLET L-SERIES. A remarkable connection between rational ELLIPTIC CURVES and modular forms is given by the TANIYAMA-SHIMURA CONJECTURE, which states that any rational ELLIPTIC CURVE is a modular form in disguise. This result was the one proved by Andrew Wiles in his celebrated proof of FERMAT'S LAST THEOREM.

See also CUSP FORM, DIRICHLET SERIES, ELLIPTIC CURVE, ELLIPTIC FUNCTION, FERMAT'S LAST THEOREM, HECKE ALGEBRA, HECKE OPERATOR, MODULAR FUNCTION, SCHLÄFLI'S MODULAR FORM, TANIYAMA-SHIMURA CONJECTURE

Modular Function

A function is said to be modular (or "elliptic modular") if it satisfies:

1. f is MEROMORPHIC in the UPPER HALF-PLANE H,
2. $f(\mathsf{A}\tau) = f(\tau)$ for every MATRIX A in the MODULAR GROUP GAMMA,
3. The LAURENT SERIES of f has the form

$$f(\tau) = \sum_{n=-m}^{m} a(n) e^{2\pi i n \tau}$$

(Apostol 1997, p. 34). Every RATIONAL FUNCTION of KLEIN'S ABSOLUTE INVARIANT J is a modular function, and every modular function can be expressed as a RATIONAL FUNCTION of J (Apostol 1997, p. 40).

An important property of modular functions is that if f is modular and not identically 0, then the number of zeros of f is equal to the number of poles of f in the closure of the FUNDAMENTAL REGION R_Γ (Apostol 1997, p. 34).

Modular Group

MODULAR GROUP GAMMA, MODULAR GROUP GAMMA0, MODULAR GROUP LAMBDA

Modular Group Gamma

The GROUP Γ of all MÖBIUS TRANSFORMATIONS OF THE FORM

$$\tau' = \frac{a\tau + b}{c\tau + d}, \tag{1}$$

where a, b, c, and d are integers with $ab - bc = 1$. The group can be represented by the 2×2 matrix

$$\mathsf{A} = \begin{bmatrix} a & b \\ c & d \end{bmatrix}, \tag{2}$$

where $\det(\mathsf{A}) = 1$. Every $\mathsf{A} \in \Gamma$ can be expressed in the form

$$\mathsf{A} = \mathsf{T}^{n_1} \mathsf{S} \mathsf{T}^{n_2} \mathsf{S} \cdots \mathsf{S} \mathsf{T}^{n_k}, \tag{3}$$

where

$$\mathsf{S} = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix} \tag{4}$$

$$\mathsf{T} = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}, \tag{5}$$

although the representation is not unique (Apostol 1997, pp. 28–9).

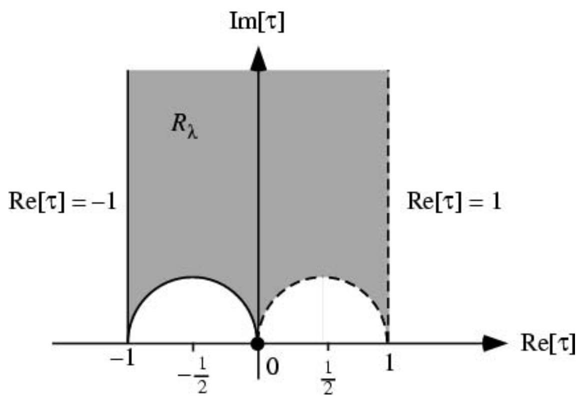
Modular Group Gamma0

Let q be a POSITIVE INTEGER, then $\Gamma_0(q)$ is defined as the set of all matrices $\begin{bmatrix} a & b \\ c & d \end{bmatrix}$ in the MODULAR GROUP GAMMA Γ with $c \equiv 0 \pmod{q}$. $\Gamma_0(q)$ is a SUBGROUP of Γ. For any PRIME p, the set

$$R_\Gamma \cup \bigcup_{k=0}^{p-1} ST^k(R_\Gamma)$$



is a FUNDAMENTAL REGION of the subgroup $\Gamma_0(q)$, where $S\tau = -1/\tau$ and $T\tau = \tau + 1$ (Apostol 1997).

See also MODULAR GROUP GAMMA0, MODULAR GROUP LAMBDA

Bracewell, R. "Modulation Theorem." *The Fourier Transform and Its Applications, 3rd ed.* New York: McGraw-Hill, p. 108, 1999.

Module

A mathematical object in which things can be added together COMMUTATIVELY by multiplying COEFFICIENTS and in which most of the rules of manipulating VECTORS hold. A module is abstractly very similar to a VECTOR SPACE, although in modules, COEFFICIENTS are taken in RINGS which are much more

general algebraic objects than the FIELDS used in VECTOR SPACES. A module taking its coefficients in a RING R is called a module over R, or a R-MODULE.

Modules are the basic tool of HOMOLOGICAL ALGEBRA. Examples of modules include the set of INTEGERS $\mathbb{Z}$, the cubic lattice in d dimensions $\mathbb{Z}^d$, and the GROUP RING of a GROUP.

$\mathbb{Z}$ is a module over itself. It is CLOSED under ADDITION and SUBTRACTION (although it is SUFFICIENT to require closure under SUBTRACTION). Numbers OF THE FORM $n\alpha$ for $n \in \mathbb{Z}$ and α a fixed integer form a submodule since, for all $(n, m) \in \mathbb{Z}$,

$$n\alpha \pm m\alpha = (n \pm m)\alpha$$

and $(n \pm m)$ is still in $\mathbb{Z}$.

Given two INTEGERS a and b, the smallest module containing a and b is the module for their GREATEST COMMON DIVISOR, $\alpha = \mathrm{GCD}(a, b)$.

Module Direct Sum

The direct sum of modules A and B is the module

$$A \oplus B = \{a \oplus b \mid a \in A,\ b \in B\}, \tag{1}$$

where all algebraic operations are defined componentwise. In particular, suppose that A and B are left R-modules, then

$$a_1 \oplus b_1 + a_2 \oplus b_2 = (a_1 + a_2) \oplus (b_1 + b_2) \tag{2}$$

and

$$r(a \oplus b) = (ra \oplus rb), \tag{3}$$

where r is an element of the RING R. The direct sum of an arbitrary family of MODULES over the same RING is also defined. If J is the indexing set for the family of MODULES, then the direct sum is represented by the collection of functions with finite support from J to the union of all these MODULES such that the function sends $j \in J$ to an element in the MODULE indexed by j.

The dimension of a direct sum is the sum of the dimensions of the quantities summed. The significant property of the direct sum is that it is the COPRODUCT in the CATEGORY of MODULES. This general definition gives as a consequence the definition of the direct sum $A \oplus B$ of ABELIAN GROUPS A and B (since they are $\mathbb{Z}$-modules, i.e., MODULES over the INTEGERS) and the direct sum of VECTOR SPACES (since they are MODULES over a FIELD). Note that the direct sum of Abelian groups is the same as the GROUP DIRECT PRODUCT, but that the term direct sum is not used for groups which are NON-ABELIAN.

Whenever C is a MODULE, with module homomorphisms $f_A : A \to C$ and $f_B : B \to C$, then there is a module homomorphism $f_A : A \oplus B \to C$, given by $f(a \oplus b) = f_A(a) + f_B(b)$. Note that this map is well-defined because addition in modules is commutative. Sometimes direct sum is preferred over direct product when the coproduct property is emphasized.

Moduli Space

This entry contributed by EDGAR VAN TUYLL

In ALGEBRAIC GEOMETRY classification problems, an ALGEBRAIC VARIETY (or other appropriate space in other parts of geometry) whose points correspond to the equivalence classes of the objects to be classified in some natural way. Moduli space can be thought of as the space of EQUIVALENCE CLASSES of COMPLEX STRUCTURES on a fixed surface of GENUS g, where two COMPLEX STRUCTURES are deemed "the same" if they are equivalent by CONFORMAL MAPPING.

See also ALGEBRAIC VARIETY, COMPLEX STRUCTURE

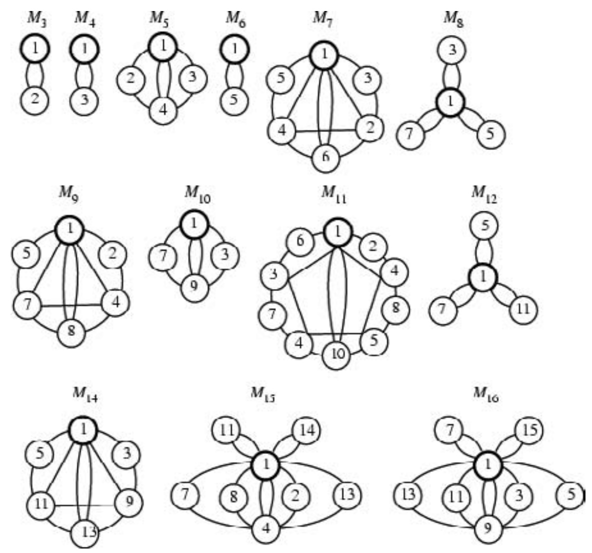
Modulo



CONGRUENCE

Modulo Multiplication Group

A FINITE GROUP M_m of RESIDUE CLASSES prime to m under multiplication mod m. M_m is ABELIAN of ORDER $\phi(m)$, where $\phi(m)$ is the TOTIENT FUNCTION. The following table gives the modulo multiplication groups of small orders, where $\mathbb{Z}_n$ denotes the CYCLIC GROUP of order n.

M_m	Group	$\phi(m)$	Elements
M_2	$\langle e \rangle$	1	1
M_3	$\mathbb{Z}_2$	2	1, 2
M_4	$\mathbb{Z}_2$	2	1, 3
M_5	$\mathbb{Z}_4$	4	1, 2, 3, 4
M_6	$\mathbb{Z}_2$	2	1, 5
M_7	$\mathbb{Z}_6$	6	1, 2, 3, 4, 5, 6
M_8	$\mathbb{Z}_2 \times \mathbb{Z}_2$	4	1, 3, 5, 7
M_9	$\mathbb{Z}_6$	6	1, 2, 4, 5, 7, 8
M_{10}	$\mathbb{Z}_4$	4	1, 3, 7, 9
M_{11}	$\mathbb{Z}_{10}$	10	1, 2, 3, 4, 5, 6, 7, 8, 9, 10
M_{12}	$\mathbb{Z}_2 \times \mathbb{Z}_2$	4	1, 5, 7, 11
M_{13}	$\mathbb{Z}_{12}$	12	1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12
M_{14}	$\mathbb{Z}_6$	6	1, 3, 5, 9, 11, 13
M_{15}	$\mathbb{Z}_2 \times \mathbb{Z}_4$	8	1, 2, 4, 7, 8, 11, 13, 14
M_{16}	$\mathbb{Z}_2 \times \mathbb{Z}_4$	8	1, 3, 5, 7, 9, 11, 13, 15
M_{17}	$\mathbb{Z}_{16}$	16	1, 2, 3, ..., 16
M_{18}	$\mathbb{Z}_6$	6	1, 5, 7, 11, 13, 17
M_{19}	$\mathbb{Z}_{18}$	18	1, 2, 3, ..., 18
M_{20}	$\mathbb{Z}_2 \times \mathbb{Z}_4$	8	1, 3, 7, 9, 11, 13, 17, 19
M_{21}	$\mathbb{Z}_2 \times \mathbb{Z}_6$	12	1, 2, 4, 5, 7, 8, 10, 11, 13, 16, 17, 19
M_{22}	$\mathbb{Z}_{10}$	10	1, 3, 5, 7, 9, 13, 15, 17, 19, 21
M_{23}	$\mathbb{Z}_{22}$	22	1, 2, 3, ..., 22
M_{24}	$\mathbb{Z}_2 \times \mathbb{Z}_2 \times \mathbb{Z}_2$	8	1, 5, 7, 11, 13, 17, 19, 23

M_m is a CYCLIC GROUP (which occurs exactly when m has a PRIMITIVE ROOT) IFF m is of one of the forms $m = 2$, 4, p^n, or $2p^n$, where p is an ODD PRIME and $n \geq 1$ (Shanks 1993, p. 92).

ISOMORPHIC modulo multiplication groups can be determined using a particular type of factorization of $\phi(m)$ as described by Shanks (1993, pp. 92–3). To perform this factorization (denoted ϕ_m), factor m in the standard form

$$m = p_1^{a_1} p_2^{a_2} \cdots p_n^{a_n}. \tag{1}$$

Now write the factorization of the TOTIENT FUNCTION involving each power of an ODD PRIME

$$\phi(p_i^{a_i}) = (p_i - 1) p_i^{a_i - 1} \tag{2}$$

as

$$\phi(p_i^{a_i}) = \left\langle q_1^{b_1} \right\rangle \left\langle q_2^{b_2} \right\rangle \cdots \left\langle q_s^{b_s} \right\rangle \left\langle p_i^{a_i - 1} \right\rangle, \tag{3}$$

where

$$p_i - 1 = q_1^{b_1} q_2^{b_2} \cdots q_s^{b_s}, \tag{4}$$

$\langle q^b \rangle$ denotes the explicit expansion of q^b (i.e., $5^2 = 25$), and the last term is omitted if $a_i = 1$. If $p_1 = 2$, write

$$\phi(2^{a_1}) = \begin{cases} 2 & \text{for } a_1 = 2 \\ 2\langle 2^{a_1 - 2} \rangle & \text{for } a_1 > 2. \end{cases} \tag{5}$$

Now combine terms from the odd and even primes. For example, consider $m = 104 = 2^3 \cdot 13$. The only odd prime factor is 13, so factoring gives $13 - 1 = 12 = \langle 2^2 \rangle \langle 3 \rangle = 3 \cdot 4$. The rule for the powers of 2 gives $2^3 = 2\langle 2^{3-2} \rangle = 2\langle 2 \rangle = 2 \cdot 2$. Combining these two gives $\phi_{104} = 2 \cdot 2 \cdot 3 \cdot 4$. Other explicit values of ϕ_m are given below.

$$\phi_3 = 2$$

$$\phi_4 = 2$$

$$\phi_5 = 4$$

$$\phi_6 = 2$$

$$\phi_{15} = 2 \cdot 4$$

$$\phi_{16} = 2 \cdot 4$$

$$\phi_{17} = 16$$

$$\phi_{104} = 2 \cdot 2 \cdot 3 \cdot 4$$

$$\phi_{105} = 2 \cdot 2 \cdot 3 \cdot 4.$$

M_m and M_n are isomorphic IFF ϕ_m and ϕ_n are identical. More specifically, the abstract GROUP corresponding to a given M_m can be determined explicitly in terms of a GROUP DIRECT PRODUCT of CYCLIC GROUPS of the so-called CHARACTERISTIC FACTORS, whose product is denoted Φ_n. This representation is obtained from ϕ_m as the set of products of largest powers of each factor of ϕ_m. For example, for ϕ_{104}, the largest power of 2 is $4 = 2^2$ and the largest power of 3 is $3 = 3^1$, so the first characteristic factor is $4 \times 3 = 12$, leaving $2 \cdot 2$ (i.e., only powers of two). The largest power remaining is $2 = 2^1$, so the second CHARACTERISTIC FACTOR is 2, leaving 2, which is the third and last CHARACTERISTIC FACTOR. Therefore, $\Phi_{104} = 2 \cdot 2 \cdot 4$, and the group M_m is isomorphic to $\mathbb{Z}_2 \times \mathbb{Z}_2 \times \mathbb{Z}_4$.

The following table summarizes the isomorphic modulo multiplication groups M_n for the first few n and identifies the corresponding abstract GROUP. No M_m is ISOMORPHIC to $\mathbb{Z}_8$, Q_8, or D_4. However, every finite ABELIAN GROUP is isomorphic to a SUBGROUP of M_m for infinitely many different values of m (Shanks 1993, p. 96). CYCLE GRAPHS corresponding to M_n for small n are illustrated above, and more complicated CYCLE GRAPHS are illustrated by Shanks (1993, pp. 87–2).

Group	Isomorphic M_m
$\langle e \rangle$	M_2
$\mathbb{Z}_2$	M_3, M_4, M_6
$\mathbb{Z}_4$	M_5, M_{10}
$\mathbb{Z}_2 \times \mathbb{Z}_2$	M_8, M_{12}
$\mathbb{Z}_6$	M_7, M_9, M_{14}, M_{18}
$\mathbb{Z}_2 \times \mathbb{Z}_4$	$M_{15}, M_{16}, M_{20}, M_{30}$
$\mathbb{Z}_2 \times \mathbb{Z}_2 \times \mathbb{Z}_2$	M_{24}
$\mathbb{Z}_{10}$	M_{11}, M_{22}
$\mathbb{Z}_{12}$	M_{13}, M_{26}
$\mathbb{Z}_2 \times \mathbb{Z}_6$	$M_{21}, M_{28}, M_{36}, M_{42}$
$\mathbb{Z}_{16}$	M_{17}, M_{34}
$\mathbb{Z}_2 \times \mathbb{Z}_8$	M_{32}
$\mathbb{Z}_2 \times \mathbb{Z}_2 \times \mathbb{Z}_4$	M_{40}, M_{48}, M_{60}
$\mathbb{Z}_{18}$	$M_{19}, M_{27}, M_{38}, M_{54}$
$\mathbb{Z}_{20}$	M_{25}, M_{50}
$\mathbb{Z}_2 \times \mathbb{Z}_{10}$	M_{33}, M_{44}, M_{66}
$\mathbb{Z}_{22}$	M_{23}, M_{46}
$\mathbb{Z}_2 \times \mathbb{Z}_{12}$	$M_{35}, M_{39}, M_{45}, M_{52}, M_{70}, M_{78}, M_{90}$
$\mathbb{Z}_{28}$	M_{29}, M_{58}
$\mathbb{Z}_{30}$	M_{31}, M_{62}
$\mathbb{Z}_{36}$	M_{37}, M_{74}

The number of CHARACTERISTIC FACTORS r of M_m for $m = 1, 2, \ldots$ are 1, 1, 1, 1, 1, 1, 1, 2, 1, 1, 1, 2, ... (Sloane's A046072). The number of QUADRATIC RESIDUES in M_m for $m > 2$ are given by $\phi(m)/2^r$ (Shanks 1993, p. 95). The first few for $m = 1, 2, \ldots$ are 0, 1, 1, 1, 2, 1, 3, 1, 3, 2, 5, 1, 6, ... (Sloane's A046073).

In the table below, $\phi(n)$ is the TOTIENT FUNCTION (Sloane's A000010) factored into CHARACTERISTIC FACTORS, $\lambda(n)$ is the CARMICHAEL FUNCTION (Sloane's A011773), and g_i are the smallest generators of the group M_n (of which there is a number equal to the number of CHARACTERISTIC FACTORS).

n	$\phi(n)$	$\lambda(n)$	g_i	n	$\phi(n)$	$\lambda(n)$	g_i
3	2	2	2	27	18	18	2
4	2	2	3	28	$2 \cdot 6$	6	13, 3

Modulus

The word modulus has several different meanings in mathematics with respect to complex numbers, congruences, elliptic integrals, quadratic invariants, sets, etc.

See also Modulus (Complex Number), Modulus (Congruence), Modulus (Elliptic Integral), Modulus (Quadratic Invariants), Modulus (Set)

Modulus (Complex Number)

The modulus of a complex number z is denoted $|z|$.

$$|x+iy| \equiv \sqrt{x^2+y^2} \quad (1)$$

$$|re^{i\phi}| = |r|. \quad (2)$$

Let $c_1 \equiv Ae^{i\phi_1}$ and $c_2 \equiv Be^{i\phi_2}$ be two complex numbers. Then

$$\left|\frac{c_1}{c_2}\right| = \left|\frac{Ae^{i\phi_1}}{Be^{i\phi_2}}\right| = \frac{A}{B}\left|e^{i(\phi_1-\phi_2)}\right| = \frac{A}{B} \quad (3)$$

$$\frac{|c_1|}{|c_2|} = \frac{|Ae^{i\phi_1}|}{|Be^{i\phi_2}|} = \frac{A}{B}\frac{|e^{i\phi_1}|}{|e^{i\phi_2}|} = \frac{A}{B}, \quad (4)$$

so

$$\left|\frac{c_1}{c_2}\right| = \frac{|c_1|}{|c_2|}. \quad (5)$$

Also,

$$|c_1 c_2| = |(Ae^{i\phi_1})(Be^{i\phi_2})| = AB|e^{i(\phi_1+\phi_2)}| = AB \quad (6)$$

$$|c_1||c_2| = |Ae^{i\phi_1}||Be^{i\phi_2}| = AB|e^{i\phi_1}||e^{i\phi_2}| = AB, \quad (7)$$

so

$$|c_1 c_2| = |c_1||c_2| \quad (8)$$

and, by extension,

$$|z^n| = |z|^n. \quad (9)$$

The only functions satisfying identities of the form

$$|f(x+iy)| = |f(x)+f(iy)| \quad (10)$$

are $f(z) = Az$, $f(z) = A\sin(bz)$, and $f(z) = A\sinh(bz)$ (Robinson 1957).

Modulus (Congruence)

The modulus of a congruence $a \equiv b \pmod{m}$ is the number m. It is the "base" with respect to which a congruence is computed (i.e., m gives the number of multiples of a that are "thrown out"). For example, when computing the time of day using a 12-hour clock obtained by adding four hours to 9:00, the answer, 1:00, is obtained by taking $9+4 \equiv 1 \pmod{12}$ (i.e., adding the hours with modulus 12).

In many computer languages (such as FORTRAN or *Mathematica*), the common residue of $b \pmod{m}$ is written `mod(b,m)` (FORTRAN) or `Mod[b,m]` (*Mathematica*).

See also Congruence

Modulus (Elliptic Integral)

A parameter k used in elliptic integrals and elliptic functions defined to be $k \equiv \sqrt{m}$, where m is the parameter. An elliptic integral is written $I(\phi, k)$ when the modulus is used. It can be computed explicitly in terms of Jacobi theta functions of zero argument:

$$k = \frac{\vartheta_2^2(0, q)}{\vartheta_3^2(0, q)}. \quad (1)$$

The real period $K(k)$ and imaginary period $K'(k) = K(k') = K(\sqrt{1-k^2})$ are given by

$$4K(k) = 2\pi\vartheta_3^2(0|\tau) \quad (2)$$

$$2iK'(k) = \pi\tau\vartheta_3^2(0|\tau), \tag{3}$$

where $K(k)$ is a complete ELLIPTIC INTEGRAL OF THE FIRST KIND and the complementary modulus is defined by

$$k'^2 \equiv 1 - k^2, \tag{4}$$

with k the modulus.

Modulus (Quadratic Invariants)

The quantity $ps - rq$ obtained by letting

$$x = pX + qY \tag{1}$$

$$y = rX + sY \tag{2}$$

in

$$ax^2 + 2bxy + cy^2 \tag{3}$$

so that

$$A = ap^2 + 2bpr + cr^2 \tag{4}$$

$$B = apq + b(ps + qr) + crs \tag{5}$$

$$C = aq^2 + 2bqs + cs^2 \tag{6}$$

and

$$B^2 - AC = (ps - rq)^2(b^2 - ac), \tag{7}$$

is called the modulus.

Modulus (Set)

The name for the SET of INTEGERS modulo m, denoted $\mathbb{Z}\backslash m\mathbb{Z}$. If m is a PRIME p, then the modulus is a FINITE FIELD $\mathbb{F}_p = \mathbb{Z}\backslash p\mathbb{Z}$.

MÖBIUS FUNCTION

Moessner's Theorem

Write down the POSITIVE INTEGERS in row one, cross out every k_1th number, and write the partial sums of the remaining numbers in the row below. Now cross off every k_2th number and write the partial sums of the remaining numbers in the row below. Continue. For every POSITIVE INTEGER $k > 1$, if every kth number is ignored in row 1, every $(k-1)$th number in row 2, and every $(k+1-i)$th number in row i, then the kth row of partial sums will be the kth POWERS 1^k, 2^k, 3^k, ...

Mollweide Projection

A MAP PROJECTION also called the ELLIPTICAL PROJECTION or HOMOLOGRAPHIC EQUAL-AREA PROJECTION. The forward transformation is

$$x = \frac{2\sqrt{2}(\lambda-\lambda_0)\cos\theta}{\pi} \quad (1)$$

$$y = 2^{1/2}\sin\theta, \quad (2)$$

where θ is given by

$$2\theta + \sin(2\theta) = \pi\sin\phi. \quad (3)$$

NEWTON'S METHOD can then be used to compute θ' iteratively from

$$\Delta\theta' = -\frac{\theta' + \sin\theta' - \pi\sin\phi}{1+\cos\theta'}, \quad (4)$$

where

$$\theta' = \tfrac{1}{2}\theta' \quad (5)$$

or, better yet,

$$\theta' = 2\sin^{-1}\left(\frac{2\phi}{\pi}\right) \quad (6)$$

can be used as a first guess.
The inverse FORMULAS are

$$\phi = \sin^{-1}\left[\frac{2\theta+\sin(2\theta)}{\pi}\right] \quad (7)$$

$$\lambda = \lambda_0 + \frac{\pi x}{2\sqrt{2}\cos\theta} \quad (8)$$

where

$$\theta = \sin^{-1}\left(\frac{y}{\sqrt{2}}\right). \quad (9)$$

Moment

The nth RAW MOMENT μ'_n (i.e., moment about zero) of a distribution $P(x)$ is defined by

$$\mu'_n = \langle x^n \rangle, \quad (1)$$

where

$$\langle f(x)\rangle = \begin{cases} \sum f(x)P(x) & \text{discrete distribution} \\ \int f(x)P(x)\,dx & \text{continuous distribution} \end{cases} \quad (2)$$

μ'_1, the MEAN, is usually simply denoted $\mu = \mu_1$. If the moment is instead taken about a point a,

$$\mu_n(a) = \langle (x-a)^n \rangle = \sum (x-a)^n P(x). \quad (3)$$

A STATISTICAL DISTRIBUTION is *not* uniquely specified by its moments, although it is by its CHARACTERISTIC FUNCTION.

The moments are most commonly taken about the MEAN. These so-called CENTRAL MOMENTS are denoted μ_n and are defined by

$$\mu_n \equiv \langle (x-\mu)^n \rangle, \quad (4)$$

$$= \int (x-\mu)^n P(x)\, dx, \quad (5)$$

with $\mu_1 = 0$. The second moment about the MEAN is equal to the VARIANCE

$$\mu_2 = \sigma^2, \quad (6)$$

where $\sigma = \sqrt{\mu_2}$ is called the STANDARD DEVIATION.

The related CHARACTERISTIC FUNCTION is defined by

$$\phi^{(n)}(0) \equiv \left[\frac{d^n \phi}{dt^n}\right]_{t=0} = i^n \mu(0). \quad (7)$$

The moments may be simply computed using the MOMENT-GENERATING FUNCTION,

$$\mu'_n = M^{(n)}(0). \quad (8)$$

Momental Skewness

$$\alpha^{(m)} \equiv \tfrac{1}{2}\gamma_1 = \frac{\mu_3}{2\sigma^3},$$

where γ_1 is the FISHER SKEWNESS.

See also FISHER SKEWNESS, SKEWNESS

Moment-Generating Function

Given a RANDOM VARIABLE $x \in R$, if there exists an $h > 0$ such thatfor $|t| < h$, then

$$M(t) \equiv \langle e^{tx} \rangle = \begin{cases} \sum_R e^{tx} P(x) & \text{for a discrete distribution} \\ \int_{-\infty}^{\infty} e^{tx} P(x)\, dx & \text{for a continuous distribution} \end{cases} \quad (1)$$

is the moment-generating function.

$$M(t) = \int_{-\infty}^{\infty} \left(1 + tx + \frac{1}{2!} t^2 x^2 + \ldots\right) P(x)\, dx$$

$$= +tm_1 + \tfrac{1}{2!} t^2 m_2 + \cdots, \quad (3)$$

where m_r is the rth MOMENT about zero. The moment-generating function satisfies

$$M_{x+y}(t) = \left\langle e^{t(x+y)} \right\rangle = \langle e^{tx} e^{ty} \rangle = \langle e^{tx} \rangle \langle e^{ty} \rangle = M_x(t) M_y(t). \quad (4)$$

If $M(t)$ is differentiable at zero, then the nth MOMENTS about the ORIGIN are given by $M^{(n)}(0)$

$$M(t) = \langle e^{tx} \rangle \quad M(0) = 1 \quad (5)$$

$$M'(t) = \langle x e^{tx} \rangle \quad M'(0) = \langle x \rangle \quad (6)$$

$$M''(t) = \langle x^2 e^{tx} \rangle \quad M''(0) = \langle x^2 \rangle \quad (7)$$

$$M^{(n)}(t) = \langle x^n e^{tx} \rangle \quad M^{(n)}(0) = \langle x^n \rangle. \quad (8)$$

The MEAN and VARIANCE are therefore

$$\mu \equiv \langle x \rangle = M'(0) \quad (9)$$

$$\sigma^2 \equiv \langle x^2 \rangle - \langle x \rangle^2 = M''(0) - [M'(0)]^2. \quad (10)$$

It is also true that

$$\mu_n = \sum_{j=0}^{n} \binom{n}{j} (-1)^{n-j} \mu'_j (\mu'_1)^{n-j}, \quad (11)$$

where $\mu'_0 = 1$ and μ'_j is the jth moment about the origin.

It is sometimes simpler to work with the LOGARITHM of the moment-generating function, which is also called the CUMULANT-GENERATING FUNCTION, and is defined by

$$R(t) \equiv \ln[M(t)] \quad (12)$$

$$R'(t) = \frac{M'(t)}{M(t)} \quad (13)$$

$$R''(t) = \frac{M(t)M''(t) - [M'(t)]^2}{[M(t)]^2} \quad (14)$$

But $M(0) = \langle 1 \rangle = 1$, so

$$\mu = M'(0) = R'(0) \quad (15)$$

$$\sigma^2 = M''(0) - [M'(0)]^2 = R''(0) \quad (16)$$

Moment Problem

The moment problem, also called "Hausdorff's moment problem "or the "little moment problem," may be stated as follows. Given a sequence of numbers $\{\mu_n\}_{n=0}^{\infty}$, under what conditions is it possible to determine a function $\alpha(t)$ of bounded variation in the interval $(0,\ 1)$ such that

$$\mu_n = \int_0^1 t^n\, d\alpha(t)$$

for $n = 0$, 1, ... Such a sequence is called a moment sequence, and Hausdorff (1921) was the first to obtain necessary and sufficient conditions for a sequence to be a moment sequence.

See also Moment, Moment Sequence

Moment Sequence

A moment sequence is a sequence $\{\mu_n\}_{n=0}^{\infty}$ defined for $n = 0$, 1, ... by

$$\mu_n = \int_0^1 t^n\, d\alpha(t),$$

where $\alpha(t)$ is a function of bounded variation in the interval $(0,\ 1)$.

Money-Changing Problem

Coin Problem

Monge-Ampère Differential Equation

A second-order partial differential equation of the form

$$Hr + 2Ks + Lt + M + N(rt - s^2) = 0, \qquad (1)$$

where H, K, L, M, and N are functions of x, y, z, p, and q, and r, s, t, p, and q are defined by

$$r = \frac{\partial^2 z}{\partial x^2} \qquad (2)$$

$$s = \frac{\partial^2 z}{\partial x\, \partial y} \qquad (3)$$

$$t = \frac{\partial^2 z}{\partial y^2} \qquad (4)$$

$$p = \frac{\partial z}{\partial x} \qquad (5)$$

$$q = \frac{\partial z}{\partial y}. \qquad (6)$$

The solutions are given by a system of differential equations given by Iyanaga and Kawada (1980).

Other equations called the Monge-Ampère equation are

$$u_{xy}^2 - u_x u_y = f(x,\ y,\ u,\ u_x,\ u_y) \qquad (7)$$

(Moon and Spencer 1969, p. 171; Zwillinger 1997, p. 134) and

$$\begin{vmatrix} u_{x_1x_1} & u_{x_1x_2} & \cdots & u_{x_1x_n} \\ u_{x_2x_1} & u_{x_2x_2} & \cdots & u_{x_2x_n} \\ \cdots & \cdots & \ddots & \cdots \\ u_{x_nx_1} & u_{x_nx_2} & \cdots & u_{x_nx_n} \end{vmatrix} = f(u,\ \mathbf{x},\ \nabla u) \qquad (8)$$

(Gilberg and Trudinger 1983, p. 441; Zwillinger 1997, p. 134).

Monge Patch

A Monge patch is a PATCH $\mathbf{x} : U \to \mathbb{R}^3$ OF THE FORM

$$\mathbf{x}(u, v) = (u, v, h(u, v)), \quad (1)$$

where U is an OPEN SET in $\mathbb{R}^2$ and $h : U \to \mathbb{R}$ is a differentiable function. The coefficients of the first FUNDAMENTAL FORM are given by

$$E = 1 + h_u^2 \quad (2)$$

$$F = h_u h_v \quad (3)$$

$$G = 1 + h_v^2 \quad (4)$$

and the second FUNDAMENTAL FORM by

$$e = \frac{h_{uu}}{\sqrt{1 + h_u^2 + h_v^2}} \quad (5)$$

$$f = \frac{h_{uv}}{\sqrt{1 + h_u^2 + h_v^2}} \quad (6)$$

$$g = \frac{g_{vv}}{\sqrt{1 + h_u^2 + h_v^2}}. \quad (7)$$

For a Monge patch, the GAUSSIAN CURVATURE and MEAN CURVATURE are

$$K = \frac{h_{uu} h_{vv} - h_{uv}^2}{(1 + h_u^2 + h_v^2)^2} \quad (8)$$

$$H = \frac{(1 - h_v^2) h_{uu} - 2 h_u h_v h_{uv} + (1 - h_u^2) h_{vv}}{2(1 + h_u^2 + h_v^2)^{3/2}}. \quad (9)$$

RADICAL CENTER

Monge's Circle Theorem

Draw three nonintersecting CIRCLES in the plane, and the common tangent line for each pair of two. The points of intersection of the three pairs of tangent lines lie on a straight line.
Monge's theorem has a 3-D analog which states that the apexes of the CONES defined by four SPHERES, taken two at a time, lie in a PLANE (when the CONES are drawn with the SPHERES on the same side of the apex; Wells 1991).

Monge's Form

A SURFACE given by the form $z = F(x, y)$.

See also MONGE PATCH

Monge's Problem

Draw a CIRCLE that cuts three given CIRCLES PERPENDICULARLY. The solution is obtained by drawing the RADICAL CENTER R of the given three CIRCLES. If it lies outside the three CIRCLES, then the CIRCLE with center R and RADIUS formed by the tangent from R to one of the given CIRCLES intersects the given CIRCLES perpendicularly. Otherwise, if R lies inside one of the circles, the problem is unsolvable.

Monge's Theorem

MONGE'S CIRCLE THEOREM, MONGE'S TETRAHEDRON THEOREM

Monica Set

The nth Monica set M_n is defined as the set of COMPOSITE NUMBERS x for which $n|S(x) - S_p(x)$, where

$$x = a_0 + a_1(10^1) + \cdots + a_d(10^d) = p_1 p_2 \cdots p_n, \quad (1)$$

and

$$S(x) = \sum_{j=0}^{d} a_j \quad (2)$$

$$S_p(x) = \sum_{i=1}^{m} S(p_i) \quad (3)$$

Every Monica set has an infinite number of elements. The Monica set M_n is a subset of the SUZANNE SET S_n. If x is a SMITH NUMBER, then it is a member of the Monica set M_n for all $n \in \mathbb{N}$. For any INTEGER $k > 1$, if x is a k-SMITH NUMBER, then $x \in M_{k-1}$.

See also SUZANNE SET

References

Smith, M. "Cousins of Smith Numbers: Monica and Suzanne Sets." *Fib. Quart.* **34**, 102–04, 1996.

Monic Polynomial

A POLYNOMIAL $x^n + a_{n-1}x^{n-1} + \cdots + a_1 x + a_0$ in which the COEFFICIENT of the highest ORDER term is 1.

See also MONOMIAL

Monkey and Coconut Problem

A DIOPHANTINE problem (i.e., one whose solution must be given in terms of INTEGERS) which seeks a solution to the following problem. Given n men and a pile of coconuts, each man in sequence takes $(1/n)$th of the coconuts left after the previous man removed his (i.e., a_1 for the first man, a_2, for the second, ..., a_n for the last) and gives m coconuts (specified in the problem to be the *same* number for each man) which do not divide equally to a monkey. When all n men have so divided, they divide the remaining coconuts n ways (i.e., taking an additional a coconuts each), and give the m coconuts which are left over to the

monkey. If m is the same at each division, then how many coconuts N were there originally? The solution is equivalent to solving the $n+1$ DIOPHANTINE EQUATIONS

$$\begin{aligned} N &= na_1 + m \\ N - a_1 - m &= na_2 + m \\ N - a_1 - a_2 - 2m &= na_3 + m \\ &\vdots \\ N - a_1 - a_2 - a_3 - \cdots - a_n - nm &= na + m, \end{aligned} \tag{1}$$

which can be rewritten as

$$\begin{aligned} N &= na_1 + m \\ (n-1)a_1 &= na_2 + m \\ (n-1)a_1 &= na_3 + m \\ &\vdots \\ (n-1)a_{n-1} &= na_n + m \\ (n-1)a_a &= na + m. \end{aligned} \tag{2}$$

Since there are $n+1$ equations in the $n+2$ unknowns a_1, a_2, ..., a_n, a, and N, the solutions span a 1-dimensional space (i.e., there is an infinite family of solution parameterized by a single value). The solution to these equations can be given by

$$N = kn^{n+1} - m(n-1), \tag{3}$$

where k is an arbitrary INTEGER (Gardner 1961).

For the particular case of $n = 5$ men and $m = 1$ left over coconuts, the 6 equations can be combined into the single DIOPHANTINE EQUATION

$$1,024N = 15,625a + 11,529, \tag{4}$$

where a is the number given to each man in the last division. The smallest POSITIVE solution in this case is $N = 15,621$ coconuts, corresponding to $k = 1$ and $a = 1,023$; Gardner 1961). The following table shows how this rather large number of coconuts is divided under the scheme described above.

Removed	Given to Monkey	Left
		15,621
3,124	1	12,496
2,499	1	9,996
1,999	1	7,996
1,599	1	6,396
1,279	1	5,116
$5 \times 1,023$	1	0

If no coconuts are left for the monkey after the final n-way division (Williams 1926), then the original number of coconuts is

$$\begin{cases} (1+nk)n^n - (n-1) & n \text{ odd} \\ (n-1+nk)n^n - (n-1) & n \text{ even.} \end{cases} \tag{5}$$

The smallest POSITIVE solution for case $n = 5$ and $m = 1$ is $N = 3,121$ coconuts, corresponding to $k = 1$ and 1,020 coconuts in the final division (Gardner 1961). The following table shows how these coconuts are divided.

Removed	Given to Monkey	Left
		3,121
624	1	2,496
499	1	1,996
399	1	1,596
319	1	1,276
255	1	1,020
5×204	0	0

A different version of the problem having a solution of 79 coconuts is considered by Pappas (1989).

Monkey Saddle

A SURFACE which a monkey can straddle with both his two legs and his tail. A simple Cartesian equation for such a surface is

$$z = x(x^2 - 3y^2), \quad (1)$$

which can also be given by the PARAMETRIC EQUATIONS

$$x(u,\ v) = u \quad (2)$$

$$y(u,\ v) = v \quad (3)$$

$$z(u,\ v) = u^3 - 3uv^2. \quad (4)$$

The coefficients of the coefficients of the FIRST FUNDAMENTAL FORM of the monkey saddle are

$$E = 1 + 9(u^2 - v^2)^2 \quad (5)$$

$$F = -18uv(u^2 - v^2) \quad (6)$$

$$G = 1 + 36u^2v^2 \quad (7)$$

and the SECOND FUNDAMENTAL FORM coefficients are

$$e = \frac{6u}{\sqrt{1 + 9(u^2 + v^2)^2}} \quad (8)$$

$$f = -\frac{6v}{\sqrt{1 + 9(u^2 + v^2)^2}} \quad (9)$$

$$g = -\frac{6u}{\sqrt{1 + 9(u^2 + v^2)^2}}, \quad (10)$$

giving RIEMANNIAN METRIC

$$ds^2 = [1 + (3u^2 - 3v^2)^2]\ du^2 - 2[18uv(u^2 - v^2)]\ du\ dv + (1 + 36u^2v^2)\ dv^2, \quad (11)$$

AREA ELEMENT

$$dA = \sqrt{1 + 9(u^2 + v^2)^2}\ du \wedge dv, \quad (12)$$

and GAUSSIAN and MEAN CURVATURES

$$K = -\frac{36(u^2 + v^2)}{[1 + 9(u^2 + v^2)^2]^2} \quad (13)$$

$$H = \frac{27u(-u^4 + 2u^2v^2 + 3v^4)}{[1 + 9(u^2 + v^2)^2]^{3/2}} \quad (14)$$

(Gray 1997). Every point of the monkey saddle except the origin has NEGATIVE GAUSSIAN CURVATURE.

Monochromatic Forced Triangle

Given a COMPLETE GRAPH K_n which is two-colored, the number of forced monochromatic TRIANGLES is at least

$$\begin{cases} \frac{1}{3}u(u-1)(u-2) & \text{for } n = 2u \\ \frac{2}{3}(u-1)(4u+1) & \text{for } n = 4u+1 \\ \frac{2}{3}u(u+1)(4u-1) & \text{for } n = 4u+3. \end{cases}$$

The first few numbers of monochromatic forced triangles are 0, 0, 0, 0, 0, 2, 4, 8, 12, 20, 28, 40, ... (Sloane's A014557).

Monodromy

A general concept in CATEGORY THEORY involving the globalization of local MORPHISMS.

See also CATEGORY THEORY, HOLONOMY, MORPHISM

Monodromy Group

A technically defined GROUP characterizing a system of linear differential equations

$$y'_j = \sum_{k=1}^{n} a_{jk}(x) y_k$$

for $j = 1,\ ...,\ n$, where a_{jk} are COMPLEX ANALYTIC FUNCTIONS of x in a given COMPLEX DOMAIN.

Monodromy Theorem

If a COMPLEX FUNCTION f is ANALYTIC in a DISK contained in a simply connected DOMAIN D and f can be ANALYTICALLY CONTINUED along every polygonal arc in D, then f can be ANALYTICALLY CONTINUED to a single-valued ANALYTIC FUNCTION on all of D!

See also ANALYTIC CONTINUATION

Monogenic Function

If

$$\lim_{z\to z_0}\frac{f(z)-f(z_0)}{z-z_0}$$

is the same for all paths in the COMPLEX PLANE, then $f(z)$ is said to be monogenic at z_0. Monogenic therefore essentially means having a single DERIVATIVE at a point. Functions are either monogenic or have infinitely many DERIVATIVES (in which case they are called POLYGENIC); intermediate cases are not possible.

Monoid

A GROUP-like object which fails to be a GROUP because elements need not have an inverse within the object. A monoid S must also be ASSOCIATIVE and have an IDENTITY ELEMENT $I \in S$ such that for all $a \in S$, $1a = a1 = a$. A monoid is therefore a SEMIGROUP with an IDENTITY ELEMENT. A monoid must contain at least one element.

The numbers of free idempotent monoids on n letters are 1, 2, 7, 160, 332381, ... (Sloane's A005345).

Monomial

A POLYNOMIAL consisting of a product of powers of variables, e.g., x, xy^2, x^2y^3z, etc. Constant coefficients are sometimes also allowed in front of a monomial.

One monomial is said to divide another if the powers of its variables are no greater than the corresponding powers in the second monomial. For example, x^2y divides x^3y but does not divide xy^3. A monomial m is said to reduce with respect to a polynomial if the leading monomial of that polynomial divides m. For example, x^2y reduces with respect to $2xy+x+3$ because xy divides x^2y, and te result of this reduction is $x^2y - x(2xy+x+3)/2$, or $-x^2/2 - 3x/2$. A polynomial can therefore be reduced by reducing its monomials beginning with the greatest and proceeding downward. Similarly, a polynomial can be reduced with respect to a set of polynomials by reducing in turn with respect to each element in that set. A polynomial is fully reduced if none of its monomials can be reduced (Lichtblau 1996).

Monomial Order

"$u < v$ implies $uw < vw$" for all monomials u, v, and w. Examples of monomial orders are the LEXICOGRAPHIC ORDER and the total degree order.

See also WELL ORDERED SET

Monomino

The unique 1-POLYOMINO, consisting of a single SQUARE.

See also DOMINO, TRIOMINO

References

Gardner, M. "Polyominoes." Ch. 13 in *The Scientific American Book of Mathematical Puzzles & Diversions.* New York: Simon and Schuster, pp. 124–40, 1959.

Monomorph

An INTEGER which is expressible in only one way in the form x^2+Dy^2 or x^2-Dy^2 where x^2 is RELATIVELY PRIME to Dy^2. If the INTEGER is expressible in more than one way, it is called a POLYMORPH.

See also ANTIMORPH, IDONEAL NUMBER, PELL EQUATION, POLYMORPH

Monomorphism

A MORPHISM $f: Y \to X$ in a CATEGORY is a monomorphism if, for any two MORPHISMS $u, v: Z \to Y$, $fu = fv$ implies that $u = v$.

See also CATEGORY, MORPHISM

Monotone

Another word for monotonic.

See also MONOTONIC FUNCTION, MONOTONIC SEQUENCE, MONOTONIC VOTING

Monotone Convergence Theorem

If $\{f_n\}$ is a sequence of MEASURABLE FUNCTIONS, with $0 \le f_n \le f_{n+1}$ for every n, then

$$\int \lim_{n\to\infty} f_n \, d\mu = \lim_{n\to\infty} \int f_n \, d\mu$$

Monotone Decreasing

Always decreasing; never remaining constant or increasing. Also called strictly decreasing.

Monotone Increasing

Always increasing; never remaining constant or decreasing. Also called strictly increasing.

Monotone Triangle

A monotone triangle (also called a strict Gelfand pattern or a gog triangle) of order n is a NUMBER TRIANGLE with n numbers along each side and the base containing entries between 1 and n such that there is strict increase across rows and weak increase diagonally up or down to the right. There is a bijection between monotone triangles of order n and ALTERNATING SIGN MATRICES of order n obtained by letting the kth row of the triangle equal the positions of 1s in the sum of the first k rows of an ALTERNATING SIGN MATRIX, as illustrated below.

$$\begin{bmatrix} 0 & 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & -1 & 1 \\ 1 & -1 & 0 & 1 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \end{bmatrix} \leftrightarrow \begin{matrix} & & & & 4 & & & & \\ & & & 2 & & 5 & & & \\ & & 1 & & 4 & & 5 & & \\ & 1 & & 3 & & 4 & & 5 & \\ 1 & & 2 & & 3 & & 4 & & 5 \end{matrix}$$

$$(0,\ 0,\ 0,\ 1,\ 0) \to 4$$

$$(0,\ 0,\ 0,\ 1,\ 0) + (0,\ 1,\ 0,\ -1,\ 1) = (0,\ 1,\ 0,\ 0,\ 1) \to 2 \quad 5$$

$$(0,\ 1,\ 0,\ 0,\ 1) + (1,\ -1,\ 0,\ 1,\ 0,\ ) = (1,\ 0,\ 0,\ 1,\ 1) \to 1 \quad 4 \quad 5$$

$$(1,\ 0,\ 0,\ 1,\ 1) + (0,\ 0,\ 1,\ 0,\ 0) = (1,\ 0,\ 1,\ 1,\ 1) \to 1 \quad 3 \quad 4 \quad 5$$

$$(1,\ 0,\ 1,\ 1,\ 1) + (0,\ 1,\ 0,\ 0,\ 0) = (1,\ 1,\ 1,\ 1,\ 1) \to 1 \quad 2 \quad 3 \quad 4 \quad 5$$

Monotonic Function

A function which is either entirely NONINCREASING or NONDECREASING. A function is monotonic if its first DERIVATIVE (which need not be continuous) does not change sign.

See also COMPLETELY MONOTONIC FUNCTION, MONOTONE, MONOTONE DECREASING, MONOTONE INCREASING, NONDECREASING FUNCTION, NONINCREASING FUNCTION

Monotonic Sequence

A SEQUENCE $\{a_n\}$ such that either (1) $a_{i+1} \ge a_i$ for every $i \ge 1$, or (2) $a_{i+1} \le a_i$ for every $i \ge 1$.

Monotonic Voting

A term in SOCIAL CHOICE THEORY meaning a change favorable for X does not hurt X.

See also ANONYMOUS, DUAL VOTING, VOTING

Monster Group

The highest order SPORADIC GROUP M. It has ORDER

$$2^{46} \cdot 3^{20} \cdot 5^9 \cdot 7^6 \cdot 11^2 \cdot 13^3 \cdot 17 \cdot 19 \cdot 23 \cdot 29 \cdot 31 \cdot 41 \cdot 47 \cdot 59 \cdot 71,$$

and is also called the FRIENDLY GIANT GROUP. It was constructed in 1982 by Robert Griess as a GROUP of ROTATIONS in 196,883-D space.

Monte Carlo Integration

In order to integrate a function over a complicated DOMAIN D, Monte Carlo integration picks random points over some simple DOMAIN D' which is a superset of D, checks whether each point is within D, and estimates the AREA of D (VOLUME, n-D CONTENT, etc.) as the AREA of D' multiplied by the fraction of points falling within D'. Monte Carlo integration is implemented in *Mathematica* as `NIntegrate[`*f*`, ..., Method->MonteCarlo]`.

An estimate of the uncertainty produced by this technique is given by

$$\int f\, dV \approx V\langle f\rangle \pm \sqrt{\frac{\langle f^2\rangle - \langle f\rangle^2}{N}}.$$

Monte Carlo Method

Any method which solves a problem by generating suitable random numbers and observing that fraction of the numbers obeying some property or properties. The method is useful for obtaining numerical solutions to problems which are too complicated to solve analytically. It is named by S. Ulam, who in 1946 became the first mathematician to dignify this approach with a name, in honor of a relative having a propensity to gamble (Hoffman 1998, p. 239).

The most common application of the Monte Carlo method is MONTE CARLO INTEGRATION.

Montel's Theorem

Let $f(z)$ be an ANALYTIC FUNCTION of z, regular in the half-strip S defined by $a < x < b$ and $y > 0$. If $f(z)$ is bounded in S and tends to a limit l as $y \to \infty$ for a certain fixed value ξ of x between a and b, then $f(z)$ tends to this limit l on every line $x = x_0$ in S, and $f(z) \to l$ uniformly for $a + \delta \le x_0 \le b - \delta$.

Monty Hall Dilemma

MONTY HALL PROBLEM

Monty Hall Problem

The Monty Hall problem is named for its similarity to the *Let's Make a Deal* television game show hosted by Monty Hall. The problem is stated as follows. Assume that a room is equipped with three doors. Behind two are goats, and behind the third is a shiny new car. You are asked to pick a door, and will win whatever is behind it. Let's say you pick door 1. Before the door is opened, however, someone who knows what's behind the doors (Monty Hall) opens *one of the other* two doors, revealing a goat, and asks you if you wish to change your selection to the third door (i.e., the door which neither you picked nor he opened). The Monty Hall problem is deciding whether you do.

The correct answer is that you *do* want to switch. If you do not switch, you have the expected 1/3 chance of winning the car, since no matter whether you initially picked the correct door, Monty will show you a door with a goat. But after Monty has eliminated one of the doors for you, you obviously do not improve your chances of winning to better than 1/3 by sticking with

your original choice. If you now switch doors, however, there is a 2/3 chance you will win the car (counterintuitive though it seems).

d_1	d_2	Winning Probability
pick	stick	1/3
pick	switch	2/3

The problem can be generalized to four doors as follows. Let one door conceal the car, with goats behind the other three. Pick a door d_1. Then the host will open one of the nonwinners and give you the option of switching. Call your new choice (which could be the same as d_1 if you don't switch) d_2. The host will then open a second nonwinner, and you must decide for choice d_3 if you want to stick to d_2 or switch to the remaining door. The probabilities of winning are shown below for the four possible strategies.

d_1	d_2	d_3	Winning Probability
pick	stick	stick	2/8
pick	switch	stick	3/8
pick	stick	switch	6/8
pick	switch	switch	5/8

The above results are characteristic of the best strategy for the n-stage Monty Hall problem: stick until the last choice, then switch.

Moore Graph

A GRAPH of type (d, k) is a REGULAR GRAPH of vertex degree $d > 2$ and GRAPH DIAMETER k which contains the maximum possible number of nodes,

$$n(d, k) = 1 + d \sum_{r=1}^{k} (d-1)^{r-1} = \frac{d(d-1)^k - 2}{d-2}$$

(Bannai and Ito 1973). Equivalently, it is a (d, g)-CAGE GRAPH, where d is the vertex degree and g is the GIRTH, with an EXCESS of zero (Wong 1982). Moore graphs are also called minimal (v, g)-graphs (Wong 1982), and are DISTANCE-REGULAR.

Hoffman and Singleton (1960) first used the term "Moore graph," and showed that there is a unique Moore graph for types (3, 2) and (7, 2), but no other $(d, 2)$ Moore graphs with the possible exception of (57, 2) (Bannai and Ito 1973). Bannai and Ito (1973) subsequently showed that there exist no Moore graphs of type (d, k) with GRAPH DIAMETER $k \geq 4$ and valence $d > 2$. Equivalently, a (v, g)-Moore graph exists only if (1) $g = 5$ and $v = 3$, 7, or (possibly) 57, or (2) $g = 6$, 8, or 12 (Wong 1982). This settled the existence and uniqueness problem from finite Moore graphs with the exception of the case (57, 2), which is still open. A proof of this theorem, sometimes called the HOFFMAN-SINGLETON THEOREM, is difficult (Hoffman and Singleton 1960, Feit and Higman 1964, Damerell 1973, Bannai and Ito 1973), but can be found in Biggs (1993).

The (3, 5)-Moore graph is the PETERSEN GRAPH, and the (7, 5)-Moore graph is the HOFFMAN-SINGLETON GRAPH. The existence of a (57, 5)-graph remains an open question.

Moore-Penrose Generalized Matrix Inverse

Given an $m \times n$ MATRIX B, the Moore-Penrose generalized MATRIX INVERSE (sometimes called the pseudoinverse) is a unique $n \times m$ MATRIX B^+ which satisfies

$$\mathsf{B}\mathsf{B}^+\mathsf{B} = \mathsf{B} \quad (1)$$

$$\mathsf{B}^+\mathsf{B}\mathsf{B}^+ = \mathsf{B}^+ \quad (2)$$

$$(\mathsf{B}\mathsf{B}^+)^{\mathrm{T}} = \mathsf{B}\mathsf{B}^+ \quad (3)$$

$$(\mathsf{B}^+\mathsf{B})^{\mathrm{T}} = \mathsf{B}^+\mathsf{B}. \quad (4)$$

It is also true that

$$\mathbf{z} = \mathsf{B}^+\mathbf{c} \quad (5)$$

is the shortest length LEAST SQUARES solution to the problem

$$\mathsf{B} = \mathbf{c}. \quad (6)$$

If the inverse of $(\mathsf{B}^{\mathrm{T}}\mathsf{B})$ exists, then

$$\mathsf{B}^+ = (\mathsf{B}^{\mathrm{T}}\mathsf{B})^{-1}\mathsf{B}^{\mathrm{T}}, \quad (7)$$

where B^{T} is the matrix TRANSPOSE, as can be seen by premultiplying both sides of (7) by B^{T} to create a SQUARE MATRIX which can then be inverted,

$$\mathsf{B}^{\mathrm{T}}\mathsf{B}_{\mathbf{z}} = \mathsf{B}^{\mathrm{T}}\mathbf{c}, \quad (8)$$

giving

$$\mathbf{z} = (\mathsf{B}^{\mathrm{T}}\mathsf{B})^{-1}\mathsf{B}^{\mathrm{T}}\mathbf{c} \equiv \mathsf{B}^+\mathbf{c}. \quad (9)$$

Mordell Conjecture

DIOPHANTINE EQUATIONS that give rise to surfaces with two or more holes have only finite many solutions in GAUSSIAN INTEGERS with no common factors. Fermat's equation has $(n-1)(n-2)/2$ HOLES, so the Mordell conjecture implies that for each INTEGER $n \geq 3$, the FERMAT EQUATION has at most a finite number of solutions. This conjecture was proved by Faltings (1984).

Morgado Identity

There are several results known as the Morgado identity. The first is

$$F_nF_{n+1}F_{n+2}F_{n+4}F_{n+5}F_{n+6}+L_{n+3}^2 = [F_{n+3}(2F_{n+2}F_{n+4}-F_{n+3}^2)]^2, \quad (1)$$

where F_n is a FIBONACCI NUMBER and L_n is a LUCAS NUMBER (Morgado 1987, Dujella 1995).

An second Morgado identity is satisfied by GENERALIZED FIBONACCI NUMBERS w_n,

$$4w_nw_{n+1}w_{n+2}w_{n+4}w_{n+5}w_{n+6} + e^2q^{2n}(w_nU_4U_5-w_{n+1}U_2U_6-w_nU_1U_8)^2 = (w_{n+1}w_{n+2}w_{n+6}+w_nw_{n+4}w_{n+5})^2, \quad (2)$$

where

$$e \equiv pab - qa^2 - b^2 \quad (3)$$

$$U_n \equiv w_n(0,\ 1;\ p,\ q) \quad (4)$$

(Morgado 1987, Dujella 1996).

Morgan-Voyce Polynomial

Polynomials related to the BRAHMAGUPTA POLYNOMIALS. They are defined by the RECURRENCE RELATIONS

$$b_n(x) = xB_{n-1}(x) + b_{n-1}(x) \quad (1)$$

$$B_n(x) = (x+1)B_{n-1}(x) + b_{n-1}(x) \quad (2)$$

for $n \geq 1$, with

$$b_0(x) = B_0(x) = 1. \quad (3)$$

Alternative recurrences are

$$b_n(x) = (x+2)b_{n-1}(x) - b_{n-2}(x) \quad (4)$$

$$B_n(x) = (x+2)B_{n-1}(x) - B_{n-2}(x) \quad (5)$$

with $b_1(x) = 1+x$ and $B_1(x) = 2+x$, and

$$b_{n+1}b_{n-1} - b_n^2 = x. \quad (6)$$

$$B_{n+1}B_{n-1} - B_n^2 = -1 \quad (7)$$

The polynomials can be given explicitly by the sums

$$B_n(x) = \sum_{k=0}^n \binom{n+k-1}{n-k} x^k \quad (8)$$

$$b_n(x) = \sum_{k=0}^n \binom{n+k}{n-k} x^k. \quad (9)$$

Defining the MATRIX

$$\mathsf{Q} = \begin{bmatrix} x+2 & -1 \\ 1 & 0 \end{bmatrix} \quad (10)$$

gives the identities

$$\mathsf{Q}^n = \begin{bmatrix} B_n & -B_{n-1} \\ B_{n-1} & -B_{n-2} \end{bmatrix} \quad (11)$$

$$\mathsf{Q}^n - \mathsf{Q}^{n-1} = \begin{bmatrix} b_n & -b_{n-1} \\ b_{n-1} & -b_{n-2} \end{bmatrix}. \quad (12)$$

Defining

$$\cos\theta = \tfrac{1}{2}(x+2) \quad (13)$$

$$\cosh\phi = \tfrac{1}{2}(x+2) \quad (14)$$

gives

$$B_n(x) = \frac{\sin[(n+1)\theta]}{\sin\theta} \quad (15)$$

$$B_n(x) = \frac{\sinh[(n+1)\phi]}{\sinh\phi} \quad (16)$$

and

$$b_n(x) = \frac{\cos\left[\frac{1}{2}(2n+1)\theta\right]}{\cos\left(\frac{1}{2}\theta\right)} \quad (17)$$

$$b_n(x) = \frac{\cosh\left[\frac{1}{2}(2n+1)\phi\right]}{\cosh\left(\frac{1}{2}\theta\right)}. \quad (18)$$

The Morgan-Voyce polynomials are related to the FIBONACCI POLYNOMIALS $F_n(x)$ by

$$b_n(x^2) = F_{2n+1}(x) \quad (19)$$

$$B_n(x^2) = \frac{1}{x} F_{2n+2}(x) \quad (20)$$

(Swamy 1968).

$B_n(x)$ satisfies the ORDINARY DIFFERENTIAL EQUATION

$$x(x+4)y'' + 3(x+2)y' - n(n+2)y = 0, \quad (21)$$

and $b_n(x)$ the equation

$$x(x+4)y'' + 2(x+1)y' - n(n+1)y = 0. \quad (22)$$

These and several other identities involving derivatives and integrals of the polynomials are given by Swamy (1968).

Morley Centers

The CENTROID of MORLEY'S TRIANGLE is called Morley's first center. It has TRIANGLE CENTER FUNCTION

$$\alpha = \cos\left(\tfrac{1}{3}A\right) + 2\cos\left(\tfrac{1}{3}B\right)\cos\left(\tfrac{1}{3}C\right).$$

The PERSPECTIVE CENTER of MORLEY'S TRIANGLE with reference TRIANGLE ABC is called Morley's second center. The TRIANGLE CENTER FUNCTION is

$$\alpha = \sec\left(\tfrac{1}{3}A\right).$$

See also CENTROID (GEOMETRIC), MORLEY'S THEOREM, PERSPECTIVE CENTER

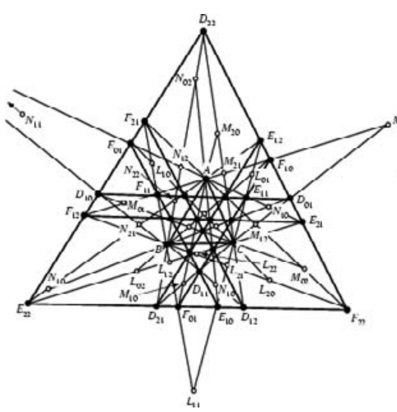
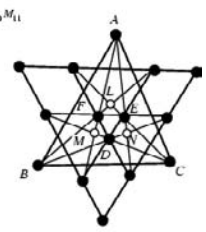
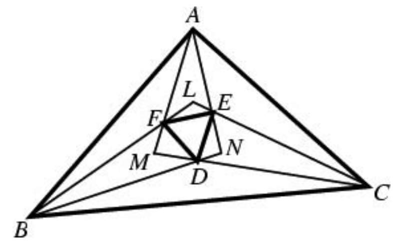
Morley's Theorem





The points of intersection of the adjacent TRISECTORS of the ANGLES of any TRIANGLE ΔABC are the VERTICES of an EQUILATERAL TRIANGLE ΔDEF known as MORLEY'S TRIANGLE. Taylor and Marr (1914) give

two geometric proofs and one trigonometric proof.



An even more beautiful result is obtained by taking the intersections of the exterior, as well as interior, angle trisectors, as shown above. In addition to the interior EQUILATERAL TRIANGLE formed by the interior trisectors, four additional equilateral triangles are obtained, three of which have sides which are extensions of a central triangle (Wells 1991).

A generalization of MORLEY'S THEOREM was discovered by Morley in 1900 but first published by Taylor and Marr (1914). Each ANGLE of a TRIANGLE ΔABC has six trisectors, since each interior angle trisector has two associated lines making angles of 120° with it. The generalization of Morley's theorem states that these trisectors intersect in 27 points (denoted D_{ij}, E_{ij}, F_{ij}, for $i, j = 0, 1, 2$) which lie six by six on nine lines. Furthermore, these lines are in three triples of PARALLEL lines, $(D_{22}E_{22},\ E_{12}D_{21},\ F_{10}F_{01})$, $(D_{22}F_{22},\ F_{21}D_{12},\ E_{01}E_{10})$, and $(E_{22}F_{22},\ F_{12}E_{21},\ D_{10}D_{01})$, making ANGLES of 60° with one another (Taylor and Marr 1914, Johnson 1929, p. 254).

Let L, M, and N be the other trisector-trisector intersections, and let the 27 points L_{ij}, M_{ij}, N_{ij} for $i, j = 0, 1, 2$ be the ISOGONAL CONJUGATES of D, E, and F. Then these points lie 6 by 6 on 9 CONICS through ΔABC. In addition, these CONICS meet 3 by 3 on the CIRCUMCIRCLE, and the three meeting points form an EQUILATERAL TRIANGLE whose sides are PARALLEL to those of ΔDEF.

Morley's Triangle

An EQUILATERAL TRIANGLE considered by MORLEY'S THEOREM with side lengths

$$8R \sin\left(\tfrac{1}{3}A\right) \sin\left(\tfrac{1}{3}B\right) \sin\left(\tfrac{1}{3}C\right),$$

where R is the CIRCUMRADIUS of the original TRIANGLE.

See also MORLEY'S THEOREM

Morphism

A morphism is a map between two objects in an abstract CATEGORY.

1. A general morphism is called a HOMOMORPHISM,
2. A morphism $f: Y \to X$ in a CATEGORY is a MONOMORPHISM if, for any two morphisms $u, v: Z \to Y$, $fu = fv$ implies that $u = v$,
3. A morphism $f: Y \to X$ in a CATEGORY is an EPIMORPHISM if, for any two morphisms $u, v: X \to Z$, $uf = vf$ implies $u = v$,
4. A bijective morphism is called an ISOMORPHISM (if there is an isomorphism between two objects, then we say they are isomorphic),
5. A surjective morphism from an object to itself is called an ENDOMORPHISM, and
6. An ISOMORPHISM between an object and itself is called an AUTOMORPHISM.

See also AUTOMORPHISM, CATEGORY, CATEGORY THEORY, EPIMORPHISM, HOMEOMORPHISM, HOMOMORPHISM, ISOMORPHISM, MONOMORPHISM, OBJECT

Morrie's Law

$$\cos(20°)\cos(40°)\cos(80°) = \tfrac{1}{8}.$$

An identity communicated to Feynman as a child by a boy named Morrie Jacobs (Gleick 1992, p. 47). Feynman remembered this fact all his life and referred to it in a letter to Jacobs in 1987 (Gleick 1992, p. 450). It is a special case of the general identity

$$2^k \prod_{j=0}^{k-1} \cos(2^j a) = \frac{\sin(2^k a)}{\sin a},$$

with $k = 3$ and $a = 20°$ (Beyer *et al.* 1996).

Morse Theory

A generalization of CALCULUS OF VARIATIONS which draws the relationship between the stationary points of a smooth real-valued function on a MANIFOLD and the global topology of the MANIFOLD. For example, if a COMPACT MANIFOLD admits a function whose only stationary points are a maximum and a minimum, then the manifold is a SPHERE. Technically speaking, Morse theory applied to a FUNCTION g on a MANIFOLD W with $g(M) = 0$ and $g(M') = 1$ shows that every COBORDISM can be realized as a finite sequence of SURGERIES. Conversely, a sequence of SURGERIES gives a COBORDISM.

There are a number of classical applications of Morse theory, including counting geodesics on a RIEMANN SURFACE and determination of the topology of a LIE GROUP (Bott 1960, Milnor 1963). Morse theory has received much attention in the last two decades as a

result of the paper by Witten (1982) which relates Morse theory to quantum field theory and also directly connects the stationary points of a smooth function to differential forms on the manifold.

Morse-Thue Sequence

THUE-MORSE SEQUENCE

Mortal

A nonempty finite set of $n \times n$ INTEGER MATRICES for which there exists some product of the MATRICES in the set which is equal to the zero MATRIX.

See also INTEGER MATRIX, MORTALITY PROBLEM

Mortality Problem

For a given n, is the problem of determining if a set is MORTAL solvable? $n = 1$ is solvable, $n = 2$ is unknown, and $n \geq 3$ is unsolvable.

See also MORTAL

Morton-Franks-Williams Inequality

Let E be the largest and e the smallest POWER of ℓ in the HOMFLY POLYNOMIAL of an oriented LINK, and i be the BRAID INDEX. Then the MORTON-FRANKS-WILLIAMS INEQUALITY holds,

$$i \geq \tfrac{1}{2}(E - e) + 1$$

(Franks and Williams 1985, Morton 1985). The inequality is sharp for all PRIME KNOTS up to 10 crossings with the exceptions of 09–42, 09–49, 10–32, 10–50, and 10–56.

Mott Polynomial

Polynomials $s_k(x)$ which form the SHEFFER SEQUENCE for

$$f(t) = -\frac{2t}{1 - t^2}$$

and have GENERATING FUNCTION

$$\sum_{k=0}^{\infty} \frac{s_k(x)}{k!} t^k = \exp\left[\frac{x(1-\sqrt{1+t^2})}{t}\right].$$

The first few are

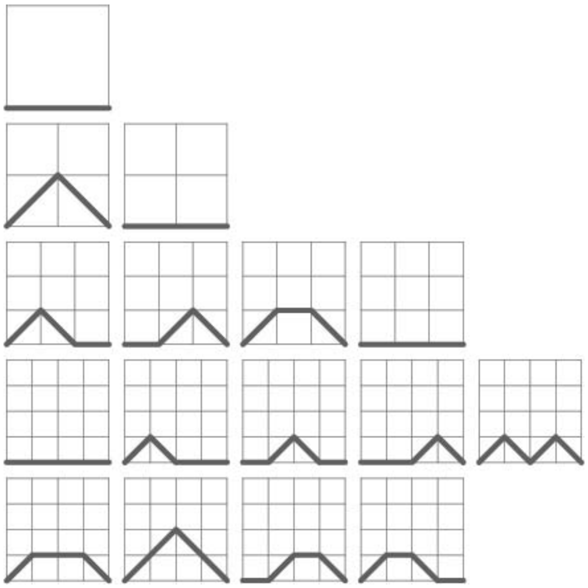
$$s_0(x) = 1$$

$$s_1(x) = -\tfrac{1}{2}x$$

$$s_2(x) = \tfrac{1}{4}x^2$$

$$s_3(x) = \tfrac{1}{8}(-x^3 + 6x)$$

$$s_4(x) = \tfrac{1}{16}(x^4 - 24x^2)$$



$$s_5(x) = \tfrac{1}{32}(-x^5 + 60x^3 - 240x).$$

Motzkin Number

The Motzkin numbers enumerate various combinatorial objects. Donaghey and Shapiro (1977) give 14 different manifestations of these numbers. In particular, they give the number of paths from (0, 0) to (n, 0) which never dip below $y = 0$ and are made up only of the steps (1, 0), (1, 1), and (1, -1), i.e., →, ↗, and ↘. The first are 1, 2, 4, 9, 21, 51, ... (Sloane's A001006). The Motzkin number GENERATING FUNCTION $M(z)$ satisfies

$$M = 1 + xM + x^2M^2 \tag{1}$$

and is given by

$$M(x) = \frac{1 - x - \sqrt{1 - 2x - 3x^2}}{2x^2}$$

$$= 1 + x + 2x^2 + 4x^3 + 9x^4 + 21x^5 + \ldots, \tag{2}$$

or by the RECURRENCE RELATION

$$M_n = M_{n-1} + \sum_{k=0}^{n-2} M_k M_{n-2-k} \tag{3}$$

with $M_0 = 1$. The Motzkin number M_n is also given by

$$M_n = -\frac{1}{2} \sum_{\substack{a+b=n+2 \\ a\geq 0,\ b\geq 0}} (-3)^a \binom{\frac{1}{2}}{a}\binom{\frac{1}{2}}{b} \tag{4}$$

$$= \frac{(-1)^{n+1}}{2^{2n+5}} \sum_{\substack{a+b=n+2 \\ a\geq 0,\ b\geq 0}} \frac{(-3)^a}{(2a-1)(2b-1)} \binom{2a}{a}\binom{2b}{b}, \tag{5}$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT.

Mousetrap

A PERMUTATION problem invented by Cayley. Let the numbers 1, 2, ..., n be written on a set of cards, and shuffle this deck of cards. Now, start counting using the top card. If the card chosen does not equal the count, move it to the bottom of the deck and continue counting forward. If the card chosen *does* equal the count, discard the chosen card and begin counting again at 1. The game is won if all cards are discarded, and lost if the count reaches $n+1$.

The number of ways the cards can be arranged such that at least one card is in the proper place for $n=1$, 2, ... are 1, 1, 4, 15, 76, 455, ... (Sloane's A002467).

Moving Average

Given a SEQUENCE $\{a_i\}_{i=1}^N$ an n-moving average is a new sequence $\{s_i\}_{i=1}^{N-n+1}$ defined from the a_i by taking the AVERAGE of subsequences of n terms,

$$s_i = \frac{1}{n}\sum_{j=1}^{i+n-1} a_j.$$

Moving Ladder Constant

N.B. A detailed online essay by S. Finch was the starting point for this entry.

What is the longest ladder which can be moved around a right-angled hallway of unit width? For a straight, rigid ladder, the answer is $2\sqrt{2}$. For a smoothly-shaped ladder, the largest diameter is $\geq 1(1+\sqrt{2})$ (Finch).

See also MOVING SOFA CONSTANT, PIANO MOVER'S PROBLEM

References

Finch, S. "Favorite Mathematical Constants." http://www.mathsoft.com/asolve/constant/sofa/sofa.html.

Moving Sofa Constant

N.B. A detailed online essay by S. Finch was the starting point for this entry.

What is the sofa of greatest AREA S which can be moved around a right-angled hallway of unit width? Hammersley (Croft *et al.* 1994) showed that

$$S \geq \frac{\pi}{2} + \frac{2}{\pi} = 2.2074\ldots. \tag{1}$$

Gerver (1992) found a sofa with larger AREA and provided arguments indicating that it is either optimal or close to it. The boundary of Gerver's sofa is a complicated shape composed of 18 ARCS. Its AREA can be given by defining the constants A, B, ϕ, and θ by solving

$$A(\cos\theta - \cos\phi) - 2B\sin\phi + (\theta - \phi - 1)\cos\theta$$
$$-\sin\theta + \cos\phi + \sin\phi = 0 \quad (2)$$

$$A(3\sin\theta + \sin\phi) - 2B\cos\phi + 3(\theta - \phi - 1)\sin\theta$$
$$+3\cos\theta - \sin\phi + \cos\phi = 0 \quad (3)$$

$$A\cos\phi - (\sin\phi + \tfrac{1}{2} - \tfrac{1}{2}\cos\phi + B\sin\phi) = 0 \quad (4)$$

$$(A + \tfrac{1}{2}\pi - \phi - \theta) - [B - \tfrac{1}{2}(\theta - \phi)(1 + A) - \tfrac{1}{4}(\theta - \phi)^2] = 0. \quad (5)$$

This gives

$$A = 0.094426560843653\ldots \quad (6)$$

$$B = 1.399203727333547\ldots \quad (7)$$

$$\phi = 0.039177364790084... \quad (8)$$

$$\theta = 0.681301509382725\ldots. \quad (9)$$

Now define

$$r(\alpha) \equiv \begin{cases} \tfrac{1}{2} \\ \quad \text{for } 0 \leq \alpha < \phi \\ \tfrac{1}{2}(1 + A + \alpha - \phi) \\ \quad \text{for } \phi \leq \alpha < \theta \\ A + \alpha - \phi \\ \quad \text{for } \theta \leq \alpha < \tfrac{1}{2}\pi - \theta \\ B - \tfrac{1}{2}\left(\tfrac{1}{2}\pi - \alpha - \phi\right)(1 + A) - \tfrac{1}{4}\left(\tfrac{1}{2}\pi - \alpha - \phi\right)^2 \\ \quad \text{for } \tfrac{1}{2}\pi - \theta \leq \alpha < \tfrac{1}{2}\pi - \phi, \end{cases} \quad (10)$$

where

$$s(\alpha) \equiv 1 - r(\alpha) \quad (11)$$

$$u(\alpha) \equiv \begin{cases} B - \tfrac{1}{2}(\alpha - \phi)(1 + A) & \text{for } \phi \leq \alpha < \theta \\ \quad -\tfrac{1}{4}(\alpha - \phi)^2 & \\ A + \tfrac{1}{2}\pi - \phi - \alpha & \text{for } \theta \leq \alpha < \tfrac{1}{4}\pi \end{cases} \quad (12)$$

$$D_u(\alpha) = \frac{du}{d\alpha}$$
$$= \begin{cases} -\tfrac{1}{2}(1 + A) - \tfrac{1}{2}(\alpha - \phi) & \text{for } \phi \leq \alpha < \theta \\ -1 & \text{if } \theta \leq \alpha < \tfrac{1}{4}\pi. \end{cases} \quad (13)$$

Finally, define the functions

$$y_1(\alpha) \equiv 1 - \int_0^\alpha r(t)\sin t\,dt \quad (14)$$

$$y_2(\alpha) \equiv 1 - \int_0^\alpha s(t)\sin t\,dt \quad (15)$$

$$y_3(\alpha) \equiv 1 - \int_0^\alpha s(t)\sin t\,dt - u(\alpha)\sin\alpha. \quad (16)$$

The AREA of the optimal sofa is given by

$$A = 2\int_0^{\pi/2-\phi} y_1(\alpha)r(\alpha)\cos\alpha\,d\alpha$$
$$+2\int_0^\theta y_2(\alpha)s(\alpha)\cos\alpha\,d\alpha$$
$$+2\int_\phi^{\pi/4} y_3(\alpha)[u(\alpha)\sin\alpha - D_u(\alpha)\cos\alpha - s(\alpha)\cos\alpha]\,d\alpha$$
$$= 2.21953166887197\ldots \quad (17)$$

(Finch).

Mrs. Perkins' Quilt

The DISSECTION of a SQUARE of side n into a number S_n of smaller squares. Unlike a PERFECT SQUARE DISSECTION, however, the smaller SQUARES need not be all different sizes. In addition, only prime dissections are considered so that patterns which can be dissected on lower order SQUARES are not permitted. The smallest numbers of RELATIVELY PRIME dissections of an $n \times n$ quilt for $n = 1, 2, ...,$ are 1, 4, 6, 7, 8, 9, 9, 10, 10, 11, 11, 11, 11, 12, ... (Sloane's A005670).

Much Greater

A strong INEQUALITY in which a is not only GREATER than b, but *much* greater (by some convention), is denoted $a \gg b$. For an astronomer, "much" may mean by a factor of 100 (or even 10), while for a mathematician, it might mean by a factor of 10^4 (or even much more).

See also GREATER, MUCH LESS

Much Less

A strong INEQUALITY in which a is not only LESS than b, but *much* less (by some convention) is denoted $a \ll b$.

See also LESS, MUCH GREATER

Mud Cracks

RIGHT ANGLE

Mu Function

The 2-argument μ-function is defined by

$$\mu(x,\ \beta) \equiv \int_0^\infty \frac{x^t t^\beta\,dt}{\Gamma(\beta+1)\Gamma(t+1)},$$

where $\Gamma(z)$ is the GAMMA FUNCTION (Erdélyi *et al.* 1981, p. 388; Prudnikov *et al.* 1990, p. 798; Gradshteyn and Ryzhik 2000, p. 1109), while the 3-argument function is defined by

$$\mu(x,\ \beta,\ \alpha) \equiv \int_0^\infty \frac{x^{\alpha+t} t^\beta\,dt}{\Gamma(\beta+1)\Gamma(\alpha+t+1)}$$

(Prudnikov *et al.* 1990, p. 798; Gradshteyn and Ryzhik 2000, p. 1109).

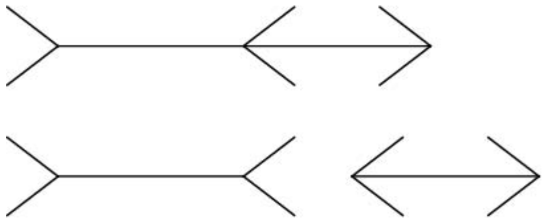
μ Molecule

MANDELBROT SET

Muirhead's Theorem

A NECESSARY and SUFFICIENT condition that $[\alpha']$ should be comparable with $[\alpha]$ for all POSITIVE values of the a is that one of (α') and (α) should be majorized by the other. If $(\alpha') \prec (\alpha)$, then

$$[\alpha'] \leq [\alpha],$$



with equality only when $((\alpha'))$ and (α) are identical or when all the a are equal. See Hardy *et al.* (1988) for a definition of notation.

Muller's Method

Generalizes the SECANT METHOD of root finding by using quadratic 3-point interpolation

$$q \equiv \frac{x_n - x_{n-1}}{x_{n-1} - x_{n-2}}. \tag{1}$$

Then define

$$A \equiv qP(x_n) - q(1+q)P(x_{n-1}) + q^2 P(x_{n-2}) \quad (2)$$

$$B \equiv (2q+1)P(x_n) - (1+q)^2 P(x_{n-1}) + q^2 P(x_{n-2}) \quad (3)$$

$$C \equiv (1+q)P(x_n), \quad (4)$$

and the next iteration is

$$x_{n+1} = x_n - (x_n - x_{n-1}) \frac{2C}{\max\left(B \pm \sqrt{B^2 - 4AC}\right)}. \quad (5)$$

This method can also be used to find COMPLEX zeros of ANALYTIC FUNCTIONS.

Mulliken Symbols

Symbols used to identify irreducible representations of GROUPS:

A = singly degenerate state which is symmetric with respect to ROTATION about the principal C_n axis,
B = singly DEGENERATE state which is antisymmetric with respect to ROTATION about the principal C_n axis,
E = doubly DEGENERATE,
T = triply DEGENERATE,
X_g = (gerade, symmetric) the sign of the wavefunction does not change on INVERSION through the center of the atom,
X_u = (ungerade, antisymmetric) the sign of the wavefunction changes on INVERSION through the center of the atom,
X_1 = (on a or b) the sign of the wavefunction does not change upon ROTATION about the center of the atom,
X_2 = (on a or b) the sign of the wavefunction changes upon ROTATION about the center of the atom,
$'$ = symmetric with respect to a horizontal symmetry plane σ_h,
$''$ = antisymmetric with respect to a horizontal symmetry plane σ_h.

Multiamicable Numbers

Two integers n and $m < n$ are (α, β)-multiamicable if

$$\sigma(m) - m = \alpha n$$

and

$$\sigma(n) - n = \beta m,$$

where $\sigma(n)$ is the DIVISOR FUNCTION and α, β are POSITIVE INTEGERS. If $\alpha = \beta = 1$, (m, n) is an AMICABLE PAIR.

m cannot have just one distinct prime factor, and if it has precisely two prime factors, then $\alpha = 1$ and m is EVEN. Small multiamicable numbers for small α, β are given by Cohen *et al.* (1995). Several of these numbers are reproduced in the table below.

α	β	m	n
1	6	76455288	183102192
1	7	52920	152280
1	7	16225560	40580280
1	7	90863136	227249568
1	7	16225560	40580280
1	7	70821324288	177124806144
1	7	199615613902848	499240550375424

Multichoose

The number of MULTISETS of length k on n symbols is sometimes termed "n multichoose k," denoted $\left(\binom{n}{k}\right)$ by analogy with the BINOMIAL COEFFICIENT. n multichoose k is given by the simple formula

$$\left(\binom{n}{k}\right) = n^k,$$

giving the following array of numbers.

$k\backslash n$	1	2	3	4
1	1	1	1	1
2	2	4	8	16
3	3	9	27	81
4	4	16	64	256

See also BINOMIAL COEFFICIENT, CHOOSE, MULTINOMIAL COEFFICIENT, MULTISET

INTEGER RELATION

Multifactorial

A generalization of the FACTORIAL and DOUBLE FACTORIAL,

$$n! = n(n-1)(n-2)\cdots 2 \cdot 1 \quad (1)$$

$$n!! = n(n-2)(n-4)\cdots \quad (2)$$

$$n!!! = n(n-3)(n-6)\cdots, \quad (3)$$

etc., where the products run through positive integers.

The FACTORIALS $n!$ for $n = 1, 2, ...,$ are 1, 2, 6, 24, 120, 720, ... (Sloane's A000142); the DOUBLE FACTORIALS $n!!$ are 1, 2, 3, 8, 15, 48, 105, ... (Sloane's A006882); the triple factorials $n!!!$ are 1, 2, 3, 4, 10, 18, 28, 80, 162, 280, ... (Sloane's A007661); and the quadruple factorials $n!!!!$ are 1, 2, 3, 4, 5, 12, 21, 32, 45, 120, ... (Sloane's A007662).

Letting $\mathrm{fac}_k(n)$ denote the k-multifactorial of n,

$$\mathrm{fac}_k(n) = \begin{cases} \prod_{i=1}^{n/k} ik & \text{for } (k,\ n) \neq 1 \\ \prod_{i=0}^{\lfloor n/k \rfloor} n - ik & \text{for } (k,\ n) = 1, \end{cases} \quad (4)$$

Define $r \equiv n/k$ then gives

$$\mathrm{fac}_k(n) = \begin{cases} k^r r! & \text{for } (k,\ n) \neq 1 \\ (-k)^{1+\lfloor r \rfloor}(-r)_{1+r} & \text{for } (k,\ n) = 1, \end{cases} \quad (5)$$

where $(x)_n$ is the POCHHAMMER SYMBOL.

Multigrade Equation

A $(k,\ l)$-multigrade equation is a DIOPHANTINE EQUATION OF THE FORM

$$\sum_{i=1}^{l} n_i^j = \sum_{i=1}^{l} m_i^j$$

for $j = 1,\ ...,\ k$, where $\mathbf{m}$ and $\mathbf{n}$ are l-VECTORS. Multigrade identities remain valid if a constant is added to each element of $\mathbf{m}$ and $\mathbf{n}$ (Madachy 1979), so multigrades can always be put in a form where the minimum component of one of the vectors is 1.

Moessner and Gloden (1944) give a bevy of multigrade equations. Small-order examples are the (2, 3)-multigrade with $\mathbf{m} = \{1,\ 6,\ 8\}$ and $\mathbf{n} = \{2,\ 4,\ 9\}$:

$$\sum_{i=1}^{3} m_i^1 = \sum_{i=1}^{3} n_i^1 = 15$$

$$\sum_{i=1}^{3} m_i^2 = \sum_{i=1}^{3} n_i^2 = 101,$$

the (3, 4)-multigrade with $\mathbf{m} = \{1,\ 5,\ 8,\ 12\}$ and $\mathbf{n} = \{2,\ 3,\ 10,\ 11\}$:

$$\sum_{i=1}^{4} m_i^1 = \sum_{i=1}^{4} n_i^1 = 26$$

$$\sum_{i=1}^{4} m_i^2 = \sum_{i=1}^{4} n_i^2 = 234$$

$$\sum_{i=1}^{4} m_i^3 = \sum_{i=1}^{4} n_i^3 = 2366,$$

and the (4, 6)-multigrade with $\mathbf{m} = \{1,\ 5,\ 8,\ 12,\ 18,\ 19\}$ and $\mathbf{n} = \{2,\ 3,\ 9,\ 13,\ 16,\ 20\}$:

$$\sum_{i=1}^{6} m_i^1 = \sum_{i=1}^{6} n_i^1 = 63$$

$$\sum_{i=1}^{6} m_i^2 = \sum_{i=1}^{6} n_i^2 = 919$$

$$\sum_{i=1}^{6} m_i^3 = \sum_{i=1}^{6} n_i^3 = 15057$$

$$\sum_{i=1}^{6} m_i^3 = \sum_{i=1}^{6} n_i^4 = 260755$$

(Madachy 1979).

A spectacular example with $k=9$ and $l=10$ is given by $\mathbf{n} = \{\pm 12, \pm 11881, \pm 20231, \pm 20885, \pm 23738\}$ and $\mathbf{m} = \{\pm 436, \pm 11857, \pm 20499, \pm 20667, \pm 23750\}$ (Guy 1994), which has sums

$$\sum_{i=1}^{9} m_i^1 = \sum_{i=1}^{9} n_i^1 = 0$$

$$\sum_{i=1}^{9} m_i^2 = \sum_{i=1}^{9} n_i^2 = 3100255070$$

$$\sum_{i=1}^{9} m_i^3 = \sum_{i=1}^{9} n_i^3 = 0$$

$$\sum_{i=1}^{9} m_i^4 = \sum_{i=1}^{9} n_i^4 = 1390452894778220678$$

$$\sum_{i=1}^{9} m_i^5 = \sum_{i=1}^{9} n_i^5 = 0$$

$$\sum_{i=1}^{9} m_i^6 = \sum_{i=1}^{9} n_i^6 = 666573454337853049941719510$$

$$\sum_{i=1}^{9} m_i^7 = \sum_{i=1}^{9} n_i^7 = 0$$

$$\sum_{i=1}^{9} m_i^8 = \sum_{i=1}^{9} n_i^8 = 330958142560259813821203262692838598$$

$$\sum_{i=1}^{9} m_i^9 = \sum_{i=1}^{9} n_i^9 = 0.$$

Rivera considers multigrade equations involving primes, consecutive primes, etc.

Multilinear Basis

See also BILINEAR BASIS

Multimagic Series

A set n distinct numbers taken from the interval $[1, n^2]$ form a MAGIC SERIES if their sum is the nth MAGIC CONSTANT

$$M_n = \tfrac{1}{2} n(n^2+1)$$

(Kraitchik 1942, p. 143). If the sum of the kth powers of these numbers is the MAGIC CONSTANT of degree k for all $k \in [1, p]$, then they are said to form a pth order MULTIMAGIC SERIES. Here, the magic constant $M_n^{(j)}$ of degree k is defined as $1/n$ times the sum of the first n^2 kth powers,

$$M_n^{(k)} = \frac{1}{n} \sum_{i=1}^{n^2} i^k = \frac{H_{n^2}^{(-p)}}{n},$$

where $H_n^{(k)}$ is a HARMONIC NUMBER of order k.

For example $\{2, 8, 9, 15\}$ is bimagic since $2+8+9+15=34$ and $2^2+8^2+9^2+15^2=374$.

The numbers of magic series of various lengths n are gives in the following table for small orders k (Kraitchik 1942, p. 76).

n	$k=1$	$k=2$	$k=3$	$k=4$
Sloane	A052456	A052457	A052458	
1	1	1	1	1
2	2	0	0	0
3	8	0	0	0
4	86	2	2	0

Multimagic Square

A MAGIC SQUARE is p-multimagic if the square formed by replacing each element by its kth power for $k=1$, 2, ..., p is also magic. A 2-multimagic square is called a BIMAGIC SQUARE, and a 3-multimagic square is called a TRIMAGIC SQUARE.

Multinomial

An algebraic expression containing more than one term (cf., BINOMIAL). The term is also used to refer to a POLYNOMIAL.

See also BINOMIAL, MULTINOMIAL COEFFICIENT, MULTINOMIAL SERIES, POLYNOMIAL

Multinomial Coefficient

The multinomial coefficients

$$(n_1,\ n_2,\ \ldots,\ n_k)!=\frac{(n_1+n_2+\cdots+n_k)!}{n_1!n_2!\cdots n_3!}$$

are the terms in the MULTINOMIAL SERIES expansion. The multinomial coefficient is returned by the *Mathematica* function `Multinomial[`*n1*, *n2*, ...`]`. The number of distinct permutations in a MULTISET of k distinct elements of multiplicity n_i $(1\le i\le k)$ is $(n_1,\ \ldots,\ n_k)$ (Skiena 1990, p. 12). The multinomial coefficients satisfy

$$\begin{aligned}(n_1,\ n_2,\ n_3,\ \ldots)&=(n_1+n_2,\ n_3,\ \ldots)(n_1,\ n_2)\\&=(n_1+n_2+n_3,\ldots)(n_1,\ n_2,\ n_3)=\ldots\end{aligned}$$

(Gosper 1972).

The CONTENT V of the d-dimensional region $\Sigma_{k=1}^{d}|x_k|^{p_k}<1$ is given by

$$V=2^d\left(\sum_{k=1}^{d}p_k^{-1},\ p_1^{-1},\ p_2^{-1},\ \ldots,\ p_d^{-1}\right).$$

Multinomial Distribution

Let a set of random variates X_1, X_2, ..., X_n have a probability function

$$P(X_1=x_1,\ \ldots,\ X_n=x_n)=\frac{N!}{\prod_{i=1}^{n}x_i!}\prod_{i=1}^{n}\theta_i^{x_i} \tag{1}$$

where x_i are POSITIVE INTEGERS such that

$$\sum_{i=1}^{n}x_i=N, \tag{2}$$

and θ_i are constants with $\theta_i>0$ and

$$\sum_{i=1}^{n} \theta_i = 1. \tag{3}$$

Then the joint distribution of X_1, ..., X_n is a multinomial distribution and $P(X_1 = x_1, \ldots, X_n = x_n)$ is given by the corresponding coefficient of the MULTINOMIAL SERIES

$$(\theta_1 + \theta_2 + \ldots + \theta_n)^N. \tag{4}$$

In the words, if X_1, X_2, ..., X_n are mutually independent events with $P(X_1) = \theta_1$, ..., $P(x_n) = \theta_n$. Then the probability that X_1 occurs x_1 times, ..., X_n occurs x_n times is given by

$$P_N(x_1, x_2, \ldots, x_n) = \frac{N!}{x_1! \cdots x_n!} \theta_1^{x_1} \cdots \theta_n^{x_n}. \tag{5}$$

(Papoulis 1984, p. 75).

The MEAN and VARIANCE of X_i are

$$\mu_i = N\theta_i \tag{6}$$

$$\sigma_i^2 = N\theta_i(1 - \theta_i). \tag{7}$$

The COVARIANCE of X_i and X_j is

$$\sigma_{ij}^2 = -N\theta_i\theta_j. \tag{8}$$

Multinomial Series

A generalization of the BINOMIAL SERIES discovered by Johann Bernoulli and Leibniz.

$$(a_1 + a_2 + \ldots + a_k)^n = \sum_{n_1, n_2, \ldots, n_k} \frac{n!}{n_1! n_2! \ldots n_k!} a_1^{n_1} a_2^{n_2} \ldots a_k^{n_k},$$

where $n \equiv n_1 + n_2 + \ldots + n_k$. The multinomial series arises in a generalization of the BINOMIAL DISTRIBUTION called the MULTINOMIAL DISTRIBUTION.

Multinomial Theorem

MULTINOMIAL SERIES

Multinormal Distribution

GAUSSIAN MULTIVARIATE DISTRIBUTION

Multiperfect Number

A number n is k-multiperfect (also called a k-MULTIPLY PERFECT NUMBER or k-PLUPERFECT NUMBER) if

$$\sigma(n) = kn$$

for some INTEGER $k > 2$, where $\sigma(n)$ is the DIVISOR FUNCTION. The value of k is called the CLASS. The special case $k = 2$ corresponds to PERFECT NUMBERS P_2, which are intimately connected with MERSENNE PRIMES (Sloane's A000396). The number 120 was long known to be 3-multiply perfect (P_3) since

$$\sigma(120) = 3 \cdot 120.$$

The following table gives the first few P_n for $n = 2, 3$, ..., 6.

2	A000396	6, 28, 496, 8128, ...,
3	A005820	120, 672, 523776, 459818240, 1476304896, 51001180160
4	A027687	30240, 32760, 2178540, 23569920, ...
5	A046060	14182439040, 31998395520, 518666803200, ...
6	A046061	154345556085770649600, 9186050031556349952000, ...

In 1900–901, Lehmer proved that P_3 has at least three distinct PRIME FACTORS, P_4 has at least four, P_5 at least six, P_6 at least nine, and P_7 at least 14.

As of 1911, 251 pluperfect numbers were known (Carmichael and Mason 1911). As of 1929, 334 pluperfect numbers were known, many of them found by Poulet. Franqui and García (1953) found 63 additional ones (five P_5s, 29 P_6s, and 29 P_7s), several of which were known to Poulet but had not been published, bringing the total to 397. Brown (1954) discovered 110 pluperfects, including 31 discovered but not published by Poulet and 25 previously published by Franqui and García (1953), for a total of 482. Franqui and García (1954) subsequently discovered 57 additional pluperfects (3 P_6s, 52 P_7s, and 2 P_8s), increasing the total known to 539.

An outdated database is maintained by R. Schroeppel, who lists 2,094 multiperfects, and up-to-date lists by J. L. Moxham (2000b) and A. Flammenkamp. It is believed that all multiperfect numbers of index 3, 4, 5, 6, and 7 are known. The number of known n-multiperfect numbers are 1, 37, 6, 36, 65, 245, 516, 1134, 1982, 183, 0, 0, ... (Moxham 2000b, Flammenkamp, Woltman 2000). Moxham (2000a) found the largest known multiperfect number, approximately equal to 7.3×10^{1345}, on Feb. 13, 2000.

If n is a P_5 number such that $3 \nmid n$, then $3n$ is a P_4 number. If $3n$ is a P_{4k} number such that $3 \nmid n$, then n is a P_{3k} number. If n is a P_3 number such that 3 (but not 5 and 9) DIVIDES n, then $45n$ is a P_4 number.

Multiple

A multiple of a number x is any quantity $y = nx$ with n an integer. If x and y are integers, then x is called a FACTOR y.

Multiple Analysis of Variance

MANOVA

Multiple-Angle Formulas

Expressions OF THE FORM $\sin(nx)$, $\cos(nx)$, and $\tan(nx)$ can be expressed in terms of $\sin x$ and $\cos x$ only using the EULER FORMULA and BINOMIAL THEOREM. For $\sin(nx)$,

$$\sin(nx) = \frac{e^{inx} - e^{-inx}}{2i} = \frac{(e^{ix})^n - (e^{-ix})^n}{2i}$$

$$= \frac{(\cos x + i \sin x)^n - (\cos x - i \sin x)^n}{2i}$$

$$= \sum_{k=0}^{n} \binom{n}{k} \frac{\cos^k x (i \sin x)^{n-k} - \cos^k x (-i \sin x)^{n-k}}{2i}$$

$$= \sum_{k=0}^{n} \binom{n}{k} \cos^k x \sin^{n-k} x \frac{i^{n-k} - (-i)^{n-k}}{2i}$$

$$= \sum_{k=0}^{n} \binom{n}{k} \cos^k x \sin^{n-k} x \sin[\tfrac{1}{2}(n-k)\pi]. \quad (1)$$

Particular cases for multiple angle formulas for $\sin x$ are given by

$$\sin(2x) = 2 \sin x \cos x \quad (2)$$

$$\sin(3x) = 3 \sin x - 4 \sin^3 x \quad (3)$$

$$\sin(4x) = 4 \sin x \cos x - 8 \sin^3 x \cos x \quad (4)$$

$$\sin(5x) = 5 \cos^4 \sin x - 10 \cos^2 x \sin^3 x + \sin^5 x. \quad (5)$$

The function $\sin(nx)$ can also be expressed as a polynomial in $\sin x$ (for n odd) or $\cos x$ times a polynomial in $\sin x$ as

$$\sin(nx) = \begin{cases} (-1)^{(n-1)/2} T_n(\sin x) & \text{for } n \text{ odd} \\ (-1)^{n/2-1} \cos x U_n(\sin x) & \text{for } n \text{ even,} \end{cases} \quad (6)$$

where T_n is a CHEBYSHEV POLYNOMIAL OF THE FIRST KIND and U_n is a CHEBYSHEV POLYNOMIAL OF THE SECOND KIND. The first few cases are

$$\sin(2x) = 2 \cos x \sin x \quad (7)$$

$$\sin(3x) = 3 \sin x - 4 \sin^3 x \quad (8)$$

$$\sin(4x) = \cos x (4 \sin x - 8 \sin^3 x) \quad (9)$$

$$\sin(5x) = 5 \sin x - 20 \sin^3 x + 16 \sin^5 x. \quad (10)$$

Similarly, $\sin(nx)$ can be expressed as $\sin x$ times a polynomial in $\cos x$ as

$$\sin(nx) = \sin x U_{n-1}(\cos x). \quad (11)$$

The first few cases are

$$\sin(2x) = 2 \cos x \sin x \quad (12)$$

$$\sin(3x) = \sin x(-1 + 4 \cos^2 x) \quad (13)$$

$$\sin(4x) = \sin x(-4 \cos x + 8 \cos^3 x) \quad (14)$$

$$\sin(5x) = \sin x(1 - 12 \cos^2 x + 16 \cos^4 x). \quad (15)$$

Bromwich (1991) gave the formula

$\sin(na) =$

$$\begin{cases} nx - \frac{n(n^2-1^2)x^3}{3!} + \frac{n(n^2-1^2)(n^2-3^2)x^5}{5!} - \ldots \\ \quad \text{for } n \text{ odd} \\ n \cos a \left[x - \frac{(n^2-2^2)x^3}{3!} + \frac{(n^2-2^2)(n^2-4^2)x^5}{5!} - \ldots \right] \\ \quad \text{for } n \text{ even,} \end{cases} \tag{16}$$

where $x = \sin a$.

For $\cos(nx)$, the multiple-angle formula can be derived as

$$\cos(nx) = \frac{e^{inx} + e^{-inx}}{2i} = \frac{(e^{ix})^n + (e^{-ix})^n}{2}$$

$$= \frac{(\cos x + i \sin x)^n + (\cos x - i \sin x)^n}{2}$$

$$= \sum_{k=0}^{n} \binom{n}{k} \frac{\cos^k x (i \sin x)^{n-k} + \cos^k x (-i \sin x)^{n-k}}{2}$$

$$= \sum_{k=0}^{n} \binom{n}{k} \cos^k x \sin^{n-k} x \frac{i^{n-k} + (-i)^{n-k}}{2}$$

$$= \sum_{k=0}^{n} \binom{n}{k} \cos^k x \sin^{n-k} x \cos\left[\tfrac{1}{2}(n-k)\pi\right]. \tag{17}$$

The first few values are

$$\cos(2x) = \cos^2 x - \sin^2 x \tag{18}$$

$$\cos(3x) = 4 \cos^3 x - 3 \cos x \sin x \tag{19}$$

$$\cos(4x) = \cos^4 x - 6 \cos^2 x \sin^2 x + \sin^4 x \tag{20}$$

$$\cos(5x) = \cos^5 x - 10 \cos^3 x \sin^2 x + 5 \cos x \sin^4 x. \tag{21}$$

The function $\cos(nx)$ can also be expressed as a polynomial in $\sin x$ (for n even) or $\cos x$ times a polynomial in $\sin x$ as

$$\cos(nx) = \begin{cases} (-1)^{n-1/2} \cos x\, U_{n-1}(\sin x) & \text{for } n \text{ odd} \\ (-1)^{n/2} T_n(\sin x) & \text{for } n \text{ even.} \end{cases} \tag{22}$$

The first few cases are

$$\cos(2x) = 1 - 2 \sin^2 x \tag{23}$$

$$\cos(3x) = \cos x(1 - 4 \sin^2 x) \tag{24}$$

$$\cos(4x) = \cos x(1 - 12 \sin^2 x + 16 \sin^4 x) \tag{25}$$

$$\cos(5x) = 1 - 8 \sin^2 x + 8 \sin^4 x. \tag{26}$$

Similarly, $\cos(nx)$ can be expressed as a polynomial in $\cos x$ as

$$\cos(nx) = T_n(\cos x) \tag{27}$$

The first few cases are

$$\cos(2x) = -1 + 2 \cos^2 x \tag{28}$$

$$\cos(3x) = -3 \cos x + 4 \cos^3 x \tag{29}$$

$$\cos(4x) = 1 - 8 \cos^2 x + 8 \cos^4 x \tag{30}$$

$$\cos(5x) = 5 \cos x - 20 \cos^3 x + 16 \cos^5 x. \tag{31}$$

Bromwich (1991) gave the formula

$$\cos(na) =$$

$$\begin{cases} \cos a \left[1 - \frac{(n^2-1^2)x^2}{2!} + \frac{(n^2-1^2)(n^2-3^2)x^4}{4!} - \cdots \right] \\ \quad n \text{ odd} \\ 1 - \frac{n^2x^2}{2!} + \frac{n^2(n^2-2^2)x^4}{4!} - \cdots \quad n \text{ even,} \end{cases} \tag{32}$$

where $x = \sin a$.

The first few multiple-angle formulas for $\tan(nx)$ are

$$\tan(2x) = \frac{2 \tan x}{1 - \tan^2 x} \tag{33}$$

$$\tan(3x) = \frac{3 \tan x - \tan^3 x}{1 - 3 \tan^2 x} \tag{34}$$

$$\tan(4x) = \frac{4 \tan x - 4 \tan^3 x}{1 - 6 \tan^2 x + \tan^4 x} \tag{35}$$

are given by Beyer (1987, p. 139) for up to $n = 6$.

Multiple angle formulas can also be written using the RECURRENCE RELATIONS

$$\sin(nx) = 2 \sin[(n-1)x] \cos x - \sin[(n-2)x] \tag{36}$$

$$\cos(nx) = 2 \cos[(n-1)x] \cos x - \cos[(n-2)x] \tag{37}$$

$$\tan(nx) = \frac{\tan[(n-1)x] + \tan x}{1 - \tan[(n-1)x] \tan x}. \tag{38}$$

Multiple-Free Set

DOUBLE-FREE SET, SUM-FREE SET, TRIPLE-FREE SET

Multiple Integral

A set of integrals taken over $n > 1$ variables

$$\underbrace{\int \cdots \int}_{n} f(x_1, \ldots, x_n)\, dx_1 \ldots dx_n \qquad (1)$$

is called a multiple integral. An nth order integral corresponds, in general, to an n-D VOLUME (CONTENT), with $n = 2$ corresponding to an AREA. In an indefinite multiple integral, the order in which the integrals are carried out can be varied at will; for definite multiple integrals, care must be taken to correctly transform the limits if the order is changed.

Multiplicand

A quantity that is multiplied by another (the MULTIPLIER). For example, in the expression $a \times b$, b is the multiplicand.

See also MULTIPLICATION, MULTIPLIER

Multiplication

In simple algebra, multiplication is the process of calculating the result when a number a is taken b times. The result of a multiplication is called the PRODUCT of a and b, and each of the numbers a and b is called a FACTOR of the PRODUCT ab. Multiplication is denoted $a \times b$, $a \cdot b$, $(a)(b)$, or simply ab. The symbol $\times$ is known as the MULTIPLICATION SIGN. Normal multiplication is ASSOCIATIVE, COMMUTATIVE, and DISTRIBUTIVE.

More generally, multiplication can also be defined for other mathematical objects such as GROUPS, MATRICES, SETS, and TENSORS.

Karatsuba and Ofman (1962) discovered that multiplication of two n digit numbers can be done with a BIT COMPLEXITY of less than n^2 using an algorithm now known as KARATSUBA MULTIPLICATION.

Multiplication of numbers x and y carried out in base b can be implemented in *Mathematica* as

```
Multiply[{x_,y_},b_]:=FromDigits[
         ListConvolve[IntegerDigits[x,    b],
IntegerDigits[y, b],
   {1, -1}, 0], b]
```

Multiplication Magic Square

128	1	32
4	16	64
8	256	2

A square which is magic under multiplication instead of addition (the operation used to define a conventional MAGIC SQUARE) is called a multiplication magic square. Unlike (normal) MAGIC SQUARES, the n^2 entries for an nth order multiplicative magic square are not required to be consecutive. The above multiplication magic square has a multiplicative magic constant of 4,096.

Multiplication Principle

If one event can occur in m ways and a second can occur independently of the first in n ways, then the two events can occur in mn ways.

Multiplication Sign

The symbol $\times$ used to denote MULTIPLICATION, i.e., $a \times b$ denotes a times b.

The symbol $\times$ is also used to denote a GROUP DIRECT PRODUCT, a CARTESIAN PRODUCT, or a direct product in the appropriate category (such as a Cartesian product of manifolds when it is implied that the smooth structure is the natural product structure.) The similar symbol $\otimes$ is reserved for a tensor product, which may rear its head in several guises, representations, bundles, modules.

Multiplication Table

A multiplication table is an array showing the result of applying a BINARY OPERATOR to elements of a given set S.

	1	2	3	4	5	6	7	8	9	10
1	1	2	3	4	5	6	7	8	9	10
2	2	4	6	8	10	12	14	16	18	20
3	3	6	9	12	15	18	21	24	27	30
4	4	8	12	16	20	24	28	32	36	40
5	5	10	15	20	25	30	35	40	45	50
6	6	12	18	24	30	36	42	48	54	60
7	7	14	21	28	35	42	49	56	63	70
8	8	16	24	32	40	48	56	64	72	80
9	9	18	27	36	45	54	63	72	81	90
10	10	20	30	40	50	60	70	80	90	100

See also BINARY OPERATOR, TRUTH TABLE

Multiplicative Character

A continuous HOMEOMORPHISM of a GROUP into the NONZERO COMPLEX NUMBERS. A multiplicative character ω gives a REPRESENTATION on the 1-D SPACE $\mathbb{C}$ of COMPLEX NUMBERS, where the REPRESENTATION action by $g \in G$ is multiplication by $\omega(g)$. A multiplicative character is UNITARY if it has ABSOLUTE VALUE 1 everywhere.

Multiplicative Digital Root

Consider the process of taking a number, multiplying its DIGITS, then multiplying the DIGITS of numbers derived from it, etc., until the remaining number has only one DIGIT. The number of multiplications required to obtain a single DIGIT from a number n is called the MULTIPLICATIVE PERSISTENCE of n, and the DIGIT obtained is called the multiplicative digital root of n.

For example, the sequence obtained from the starting number 9876 is (9876, 3024, 0), so 9876 has a MULTIPLICATIVE PERSISTENCE of two and a multiplicative digital root of 0. The multiplicative digital roots of the first few positive integers are 1, 2, 3, 4, 5, 6, 7, 8, 9, 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 0, 2, 4, 6, 8, 0, 2, 4, 6, 8, 0, 3, 6, 9, 2, 5, 8, 2, ... (Sloane's A031347).

n	Sloane	numbers having multiplicative digital root n
0	A034048	0, 10, 20, 25, 30, 40, 45, 50, 52, 54, 55, 56, 58, ...
1	A002275	1, 11, 111, 1111, 11111, 111111, 1111111, 11111111, ...
2	A034049	2, 12, 21, 26, 34, 37, 43, 62, 73, 112, 121, 126, ...
3	A034050	3, 13, 31, 113, 131, 311, 1113, 1131, 1311, 3111, ...
4	A034051	4, 14, 22, 27, 39, 41, 72, 89, 93, 98, 114, 122, ...

5	A034052	5, 15, 35, 51, 53, 57, 75, 115, 135, 151, 153, 157, ...
6	A034053	6, 16, 23, 28, 32, 44, 47, 48, 61, 68, 74, 82, 84, ...
7	A034054	7, 17, 71, 117, 171, 711, 1117, 1171, 1711, 7111, ...
8	A034055	8, 18, 24, 29, 36, 38, 42, 46, 49, 63, 64, 66, 67, ...
9	A034056	9, 19, 33, 91, 119, 133, 191, 313, 331, 911, 1119, ...

Multiplicative Function

A function $f(m)$ is called multiplicative if $(m, m') = 1$ (i.e., the statement that m and m' are RELATIVELY PRIME) implies

$$f(mm') = f(m)f(m').$$

Examples of multiplicative functions are the MÖBIUS FUNCTION and TOTIENT FUNCTION.

See also COMPLETELY MULTIPLICATIVE FUNCTION, MÖBIUS FUNCTION, QUADRATIC RESIDUE, TOTIENT FUNCTION

Multiplicative Inverse

The multiplicative inverse of a REAL or COMPLEX NUMBER z is its RECIPROCAL $1/z$. For complex $z = x + iy$,

$$\frac{1}{z} = \frac{1}{x+iy} = \frac{x}{x^2+y^2} - i\frac{y}{x^2+y^2}.$$

Multiplicative Number Theory

Multiplicative Order

Let n be a positive number having PRIMITIVE ROOTS. If g is a PRIMITIVE ROOT of n, then the numbers 1, g, g^2, ..., $g^{\phi(n)-1}$ form a REDUCED RESIDUE SYSTEM modulo n, where $\phi(n)$ is the TOTIENT FUNCTION. In this set, there are $\phi(\phi(n))$ PRIMITIVE ROOTS, and these are the numbers g^c, where c is RELATIVELY PRIME to $\phi(n)$. If a is an arbitrary integer RELATIVELY PRIME to n, then there exists among the numbers 0, 1, 2, ..., $\phi(n-1)$ exactly one number μ such that

$$a \equiv g^\mu \pmod{n}. \tag{1}$$

The number μ is then called the generalized multiplicative order of a with respect to the base g modulo n. Note that Nagell (1951, p. 112) instead uses the term "index" and writes

$$\mu = \operatorname{ind}_g a \pmod{n}. \tag{2}$$

For example, the number 7 in the least positive PRIMITIVE ROOT of $n = 41$, and since $15 \equiv 7^3 \pmod{41}$, the number 15 has multiplicative order 3 with respect to base 7 (modulo 41) (Nagell 1951, p. 112). The generalized multiplicative order is implemented in *Mathematica* as `MultiplicativeOrder[`a, n, {$g1$}`]`, or more generally as `MultiplicativeOrder[`a, n, {$g1$, $g2$, ...}`]`.

If the PRIMITIVE ROOTS $g_1 = -1$ and $g_2 = 1$ are chosen, the resulting function is called the SUBORDER FUNCTION and is denoted $\operatorname{sord}_n(a)$. If the single PRIMITIVE ROOT $g_1 = 1$ is chosen, then the function reduces to "the" (i.e., ungeneralized) multiplicative order, denoted $\operatorname{ord}_n(a)$, implemented in *Mathematica* as `MultiplicativeOrder[`a, n`]`. This function is sometimes also known as the discrete logarithm (or, more confusingly, as the "index," a term which Nagell applied to the case of general g).

Multiplicative Perfect Number

A number n for which the PRODUCT of DIVISORS is equal to n^2. The first few are 1, 6, 8, 10, 14, 15, 21, 22, ... (Sloane's A007422).

See also PERFECT NUMBER

References

Sloane, N. J. A. Sequences A007422/M4068 in "An On-Line Version of the Encyclopedia of Integer Sequences." http://www.research.att.com/~njas/sequences/eisonline.html.

Multiplicative Persistence

Multiply all the digits of a number n by each other, repeating with the product until a single DIGIT is obtained. The number of steps required is known as the multiplicative persistence, and the final DIGIT obtained is called the MULTIPLICATIVE DIGITAL ROOT of n.

For example, the sequence obtained from the starting number 9876 is (9876, 3024, 0), so 9876 has an multiplicative persistence of two and a MULTIPLICATIVE DIGITAL ROOT of 0. The multiplicative persistences of the first few positive integers are 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 2, 2, 2, 2, 2, 1, 1, 1, 1, 2, 2, 2, 2, 2, 3, 1, 1, ... (Sloane's A031346). The smallest numbers having multiplicative persistences of 1, 2, ... are 10, 25, 39, 77, 679, 6788, 68889, 2677889, 26888999, 3778888999, 277777788888899, ... (Sloane's A003001; Wells 1986, p. 78). There is no number $< 10^{50}$ with multiplicative persistence > 11 (Wells 1986, p. 78). It is conjectured that the maximum number lacking the DIGIT 1 with persistence 11 is

$$77777733332222222222222222222$$

There is a stronger conjecture that there is a maximum number lacking the DIGIT 1 for each persistence ≥ 2.

The maximum multiplicative persistence in base 2 is 1. It is conjectured that all powers of $2 > 2^{15}$ contain a 0 in base 3, which would imply that the maximum persistence in base 3 is 3 (Guy 1994).

The multiplicative persistence of an n-DIGIT number is also called its LENGTH. The maximum lengths for $n = 1$-, 2-, 3-, ..., digit numbers are 0, 4, 5, 6, 7, 7, 8, 9, 9, 10, 10, 10, ... (Sloane's A014553; Beeler 1972, Gottlieb 1969–970). The numbers of n-digit numbers having maximal multiplicative persistence for $n = 1$, 2, ..., are 10 (which includes the number 0), 1, 9, 12, 20, 2430, ... (Sloane's A046148). The smallest n-digit numbers with maximal multiplicative persistence are 0, 77, 679, 6788, 68889, 168889, ... (Sloane's A046149). The largest n-digit numbers with maximal multiplicative persistence are 9, 77, 976, 8876, 98886, 997762, ... (Sloane's A046150). The number of distinct n-digit numbers (except for 0s) are given by $\binom{10+n-1}{n} - 1$ which, for $n = 1$, 2, 3, ..., gives 54, 219, 714, 2001, 5004, 11439, ... (Sloane's A035927).

The concept of multiplicative persistence can be generalized to multiplying the kth powers of the digits of a number and iterating until the result remains constant. All numbers other than REPUNITS, which converge to 1, converge to 0. The number of iterations required for the kth powers of a number's digits to converge to 0 is called its k-multiplicative persistence. The following table gives the n-multiplicative persistences for the first few positive integers.

n	Sloane	n-Persistences
2	Sloane's A031348	0, 7, 6, 6, 3, 5, 5, 4, 5, 1, ...
3	Sloane's A031349	0, 4, 5, 4, 3, 4, 4, 3, 3, 1, ...
4	Sloane's A031350	0, 4, 3, 3, 3, 3, 2, 2, 3, 1, ...
5	Sloane's A031351	0, 4, 4, 2, 3, 3, 2, 3, 2, 1, ...
6	Sloane's A031352	0, 3, 3, 2, 3, 3, 3, 3, 3, 1, ...
7	Sloane's A031353	0, 4, 3, 3, 3, 3, 3, 2, 3, 1, ...
8	Sloane's A031354	0, 3, 3, 3, 2, 4, 2, 3, 2, 1, ...
9	Sloane's A031355	0, 3, 3, 3, 3, 2, 2, 3, 2, 1, ...
10	Sloane's A031356	0, 2, 2, 2, 3, 2, 3, 2, 2, 1, ...

Erdos suggested ignoring all zeros and showed that at most $c \ln \ln n$ steps are needed to reduce n to a single digit, where c depends on the base.

The smallest primes with multiplicative persistences $n = 1$, 2, 3, ... are 2, 29, 47, 277, 769, 8867, 186889, 2678789, 26899889, 3778888999, 277777788888989, ... (Sloane's A046500).

Multiplicative Primitive Residue Class Group

MODULO MULTIPLICATION GROUP

Multiplicity

The word multiplicity is a general term meaning "the number of values for which a given condition holds." For example, the term is used to refer to the value of the TOTIENT VALENCE FUNCTION or the number of times a given polynomial equation has a ROOT at a given point.

Let z_0 be a ROOT of a function f, and let n be the least positive integer n such that $f^{(n)}(z_0) \neq 0$. Then the POWER SERIES of f about z_0 begins with the nth term,

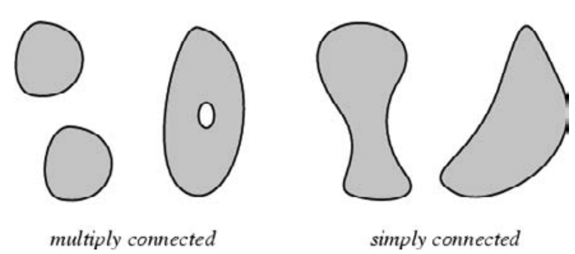
$$f(z) = \sum_{j=n}^{\infty} \frac{1}{j!} \frac{\partial^j f}{\partial z^j}\bigg|_{z=z_0} (z - z_0)^j,$$

and f is said to have a ROOT of multiplicity (or "order") n. If $n = 1$, the ROOT is called a SIMPLE ROOT (Krantz 1999, p. 70).

See also DEGENERATE, MULTIPLE ROOT, NOETHER'S FUNDAMENTAL THEOREM, ROOT, SIMPLE ROOT, TOTIENT VALENCE FUNCTION

References

Krantz, S. G. "Zero of Order n." §5.1.3 in *Handbook of Complex Analysis.* Boston, MA: Birkhäuser, p. 70, 1999.



Multiplier

A quantity by which another (the MULTIPLICAND) is multiplied. For example, in the expression $a \times b$, a is the multiplier.

The term "multiplier" also has a special meaning in the theory of MODULAR FUNCTION.

See also MODULAR FUNCTION, MULTIPLICAND, MULTIPLICATION

Multiply Connected

A set which is CONNECTED but not SIMPLY CONNECTED is called multiply connected. A SPACE is n-MULTIPLY CONNECTED if it is $(n-1)$-connected and if every MAP from the n-SPHERE into it extends continuously over the $(n+1)$-DISK

A theorem of Whitehead says that a SPACE is infinitely connected IFF it is contractible.

See also CONNECTIVITY, LOCALLY PATHWISE-CONNECTED PATHWISE-CONNECTED, SIMPLY CONNECTED

Multiply Perfect Number

MULTIPERFECT NUMBER

Multipolynomial Quadratic Sieve

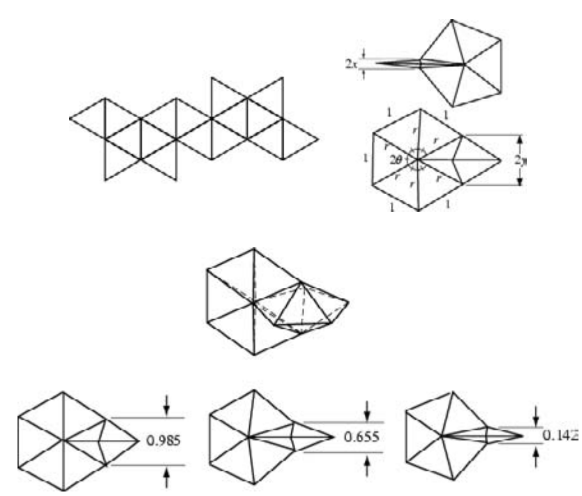
QUADRATIC SIEVE

Multisection

SERIES MULTISECTION

Multiset

A SET-like object in which order is ignored, but multiplicity is explicitly significant. Therefore, multisets $\{1, 2, 3\}$ and $\{2, 1, 3\}$ are equivalent, but $\{1, 1, 2, 3\}$ and $\{1, 2, 3\}$ differ.



See also LIST, MULTICHOOSE, MULTINOMIAL COEFFICIENT, SET

References

Skiena, S. *Implementing Discrete Mathematics: Combinatorics and Graph Theory with Mathematica.* Reading, MA: Addison-Wesley, p. 12, 1990.

Multistable

A structure such as a polyhedron which can change form from one stable configuration to another with only a slight transient nondestructive elastic stretch (Goldberg 1978). The simplest example of a polyhedron having multistable forms is Wunderlich's bistable JUMPING OCTAHEDRON (Cromwell 1991, pp. 222–23).

Goldberg (1978) give two tristable polyhedra: one having 12 faces and one having 20. Goldberg's bistable icosahedron, illustrated above, consists of two adjoined PENTAGONAL DIPYRAMIDS, each with two adjacent triangles (one on top and one on bottom) omitted (Goldberg 1978; Wells 1991; Cromwell 1997, pp. 222 and 224). The variables in the schematic

above are connected by the equations

$$\sin\,\theta = \frac{1}{2r}$$

$$x^2 = 1 - r^2$$

$$y = r\,\sin(5\theta) = r(5\,\sin\,\theta - 20\,\sin^3\,\theta + 15\,\sin^5\,\theta)$$

$$= r\,\sin\,\theta(5 - 20\,\sin^2\,\theta + 16\,\sin^4\,\theta)$$

$$= \frac{1}{2}\left(5 - \frac{5}{r^2} + \frac{1}{r^4}\right).$$

Plugging in $r^2 = 1 - x^2$ and setting $y = x$ gives the QUINTIC EQUATION

$$2x^5 - 4x^2 - 4x^3 + 5x^2 + 2x - 1 = 0,$$

which has smallest positive solution $x \approx 0.327267$. Goldberg gives $(x,\ y) = (0.071,\ 0.49)$ and $(0.49,\ 0.071)$ as other solutions, although it's not clear where these come from.

GAUSSIAN JOINT VARIABLE THEOREM

Mu Molecule

MANDELBROT SET

Müntz Space

A Müntz space is a technically defined SPACE

$$M(\Lambda) \equiv \operatorname{span}\{x^{\lambda_0},\ x^{\lambda_1},\ \ldots\}$$

which arises in the study of function approximations.

Müntz's Theorem

Müntz's theorem is a generalization of the WEIERSTRASS APPROXIMATION THEOREM, which states that any continuous function on a closed and bounded interval can be uniformly approximated by POLYNOMIALS involving constants and any INFINITE SEQUENCE of POWERS whose RECIPROCALS diverge.

In technical language, Müntz's theorem states that the MÜNTZ SPACE $M(\Lambda)$ is dense in $C[0,\ 1]$ IFF

$$\sum_{i=1}^{\infty} \frac{1}{\lambda_i} = \infty.$$

See also WEIERSTRASS APPROXIMATION THEOREM

Mutant Knot

Given an original KNOT K, the knots produced by MUTATIONS together with K itself are called mutant knots. Mutant knots are often difficult to distinguish. For instance, mutants have the same HOMFLY POLYNOMIALS and HYPERBOLIC KNOT volume. Many but not all mutants also have the same GENUS (KNOT).

See also KNOT, MUTATION

Mutation

Consider a KNOT as being formed from two TANGLES. The following three operations are called mutations.

1. Cut the knot open along four points on each of the four strings coming out of T_2, flipping T_2 over, and gluing the strings back together.
2. Cut the knot open along four points on each of the four strings coming out of T_2, flipping T_2 to the right, and gluing the strings back together.
3. Cut the knot, rotate it by 180°, and reglue. This is equivalent to performing (1), then (2).

Mutations applied to an alternating KNOT projection always yield an ALTERNATING KNOT. The mutation of a KNOT is always another KNOT (a opposed to a LINK).

See also KNOT, MUTANT KNOT, TANGLE

Mutual Information

This entry contributed by ERIK G. MILLER

The mutual information between two discrete RANDOM VARIABLES X and Y is defined to be

$$I(X;\ Y) = \sum_{x \in \chi} \sum_{y \in Y} p(x,\ y) \ln\left(\frac{p(x,\ y)}{p(x)p(y)}\right). \qquad (1)$$

bits. Additional properties are

$$I(X;\ Y) = I(Y;\ X), \qquad (2)$$

$$I(X;\ Y) \geq 0, \qquad (3)$$

and

$$I(X;\ Y) = H(X) + H(Y) - H(X,\ Y), \qquad (4)$$

where $H(X)$ is the ENTROPY of the RANDOM VARIABLE X and $H(X, Y)$ is the joint entropy of these variables.

See also ENTROPY

N

N

The SET of NATURAL NUMBERS (the POSITIVE INTEGERS Z+ 1, 2, 3, ...; Sloane's A000027), denoted ℕ, also called the WHOLE NUMBERS. Like whole numbers, there is no general agreement on whether 0 should be included in the list of natural numbers.

Due to lack of standard terminology, the following terms are recommended in preference to "COUNTING NUMBER," "natural number," and "WHOLE NUMBER."

set	name	symbol
..., -2, -1, 0, 1, 2, ...	INTEGERS	Z
1, 2, 3, 4, ...	POSITIVE INTEGERS	Z+
0, 1, 2, 3, 4, ...	NONNEGATIVE INTEGERS	Z*
0, -1, -2, -3, -4, ...	NONPOSITIVE INTEGERS	
-1, -2, -3, -4, ...	NEGATIVE INTEGERS	Z$_-$

See also C, CARDINAL NUMBER, COUNTING NUMBER, I, INTEGER, Q, R, WHOLE NUMBER, Z, Z+

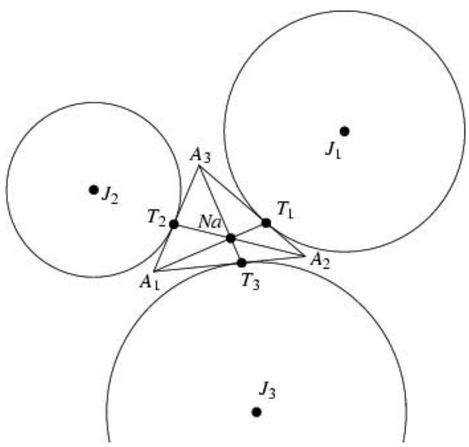
DEL, LAPLACIAN

Nagel Line

The Nagel line is the term proposed for the first time in this work for the line on which the INCENTER I, CENTROID G, SPIEKER CENTER Sp, and NAGEL POINT Na lie. The points satisfy

$$ISp = SpNa$$



$$IG = \tfrac{1}{2}GNa.$$

See also CENTROID (TRIANGLE), INCENTER, NAGEL POINT, SPIEKER CENTER

References

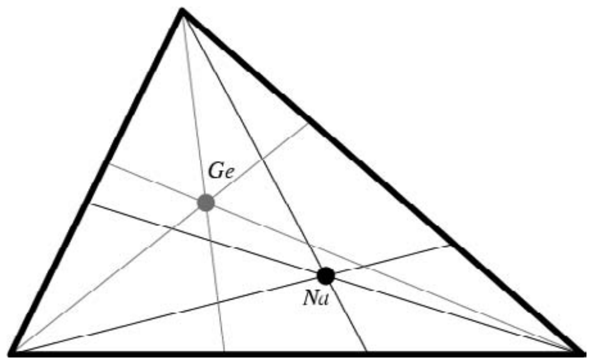
Nagel Point



Let T_1 be the point at which the J_1-EXCIRCLE meets the side A_2A_3 of a TRIANGLE $\Delta A_1A_2A_3$, and define T_2 and T_3 similarly. Then the lines T_1, T_2, and T_3 CONCUR in the NAGEL POINT Na (sometimes denoted M)

The points T_1, T_2, and T_3 can also be constructed as the points which bisect the PERIMETER of $\Delta A_1A_2A_3$ starting at A_1, A_2, and A_3. Then the lines A_1T_1, A_2T_2, and A_3T_3 (sometimes called SPLITTERS) concur in the Nagel point Na. For this reason, the Nagel point is sometimes known as the BISECTED PERIMETER POINT (Bennett *et al.* 1988, Chen *et al.* 1992, Kimberling 1994), although the CLEAVANCE CENTER is also a bisected perimeter point.

The Nagel point has TRIANGLE CENTER FUNCTION

$$\alpha = \frac{b+c-a}{a}.$$

The Nagel point lies on the NAGEL LINE. The ORTHOCENTER and Nagel point form a DIAMETER of the FUHRMANN CIRCLE.

The Nagel point Na is also the ISOTOMIC CONJUGATE POINT of the GERGONNE POINT Ge.

Naive Set Theory

A branch of mathematics which attempts to formalize the nature of the SET using a minimal collection of independent axioms. Unfortunately, as discovered by its earliest proponents, naive set theory quickly runs into a number of PARADOXES (such as RUSSELL'S PARADOX), so a less sweeping and more formal theory known as AXIOMATIC SET THEORY must be used.

See also AXIOMATIC SET THEORY, RUSSELL'S PARADOX, SET THEORY

NAND

NAND gate

A CONNECTIVE in LOGIC equivalent to the composition NOT AND that yields TRUE if any condition is TRUE, and FALSE if all conditions are TRUE. A NAND B is equivalent to $!(A \wedge B)$, where $!A$ denotes NOT and $\wedge$ denotes AND. In PROPOSITIONAL CALCULUS, the term ALTERNATIVE DENIAL is used to refer to the NAND connective. Notations for NAND include $A \barwedge B$ and $A|B$ (Mendelson 1997, p. 26). The NAND operation is implemented in *Mathematica* 4.1 as Nand[A, B, ...]. The circuit diagram symbol for an NAND gate is illustrated above.

The BINARY NAND operator has the following TRUTH TABLE (Mendelson 1997, p. 27).

A	B	$A \barwedge B$
T	T	F
T	F	T
F	T	T
F	F	T

The NAND operation is the basic logical operation performed by the solid-state transistors ("NAND gates") that underlie virtually all integrated circuits and modern computers. The first axiom system based on NAND was given by Henry Sheffer in 1913. In their landmark tome, Whitehead and Russell (1927) promoted NAND as the appropriate foundation for axiomatic logic.

The AND function $A \wedge B$ can be written in terms of NANDs as

$$A \wedge B = (A \bar{\wedge} B) \bar{\wedge} (A \bar{\wedge} B).$$

Napierian Logarithm

Write a number N as

$$N = 10^7 (1 - 10^{-7})^L,$$

then L is the Napierian logarithm of N. This was the original definition of a LOGARITHM, and can be given in terms of the modern LOGARITHM as

$$L(N) = -\frac{\log\left(\frac{n}{10^7}\right)}{\log\left(\frac{10^7}{10^7 - 1}\right)}.$$

The Napierian logarithm decreases with increasing numbers and does not satisfy many of the fundamental properties of the modern LOGARITHM, e.g.,

$$N \log(xy) \neq N \log x + N \log y.$$

Napier's Analogies

Let a SPHERICAL TRIANGLE have sides a, b, and c with A, B, and C the corresponding opposite angles. Then

$$\frac{\sin\left[\frac{1}{2}(A - B)\right]}{\sin\left[\frac{1}{2}(A + B)\right]} = \frac{\tan\left[\frac{1}{2}(a - b)\right]}{\tan\left(\frac{1}{2}c\right)} \quad (1)$$

$$\frac{\cos\left[\frac{1}{2}(A - B)\right]}{\cos\left[\frac{1}{2}(A + B)\right]} = \frac{\tan\left[\frac{1}{2}(a + b)\right]}{\tan\left(\frac{1}{2}c\right)} \quad (2)$$

$$\frac{\sin\left[\frac{1}{2}(a - b)\right]}{\sin\left[\frac{1}{2}(a + b)\right]} = \frac{\tan\left[\frac{1}{2}(A - B)\right]}{\cot\left(\frac{1}{2}C\right)} \quad (3)$$

$$\frac{\cos\left[\frac{1}{2}(a - b)\right]}{\cos\left[\frac{1}{2}(a + b)\right]} = \frac{\tan\left[\frac{1}{2}(A + B)\right]}{\cot\left(\frac{1}{2}C\right)} \quad (4)$$

(Smart 1960, p. 23).

SPHERICAL RING

Napoleon Points

The inner Napoleon point N is the CONCURRENCE of lines drawn between VERTICES of a given TRIANGLE ΔABC and the opposite VERTICES of the corresponding inner NAPOLEON TRIANGLE $\Delta N_{AB}N_{AC}N_{BC}$. The TRIANGLE CENTER FUNCTION of the inner Napoleon point is

$$\alpha = \csc\left(A - \tfrac{1}{6}\pi\right).$$

The outer Napoleon point N' is the CONCURRENCE of lines drawn between VERTICES of a given TRIANGLE ΔABC and the opposite VERTICES of the corresponding outer NAPOLEON TRIANGLE $\Delta N'_{AB}N'_{AC}N'_{BC}$. The TRIANGLE CENTER FUNCTION of the point is

$$\alpha = \csc\left(A + \tfrac{1}{6}\pi\right).$$

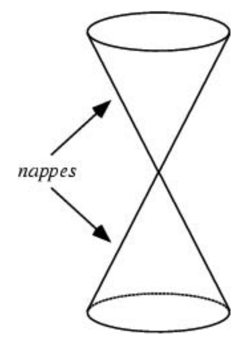
Napoleon's Theorem

If EQUILATERAL TRIANGLES are erected externally on the sides of any TRIANGLE, then the centers form an EQUILATERAL TRIANGLE (the outer NAPOLEON TRIANGLE). Furthermore, the inner NAPOLEON TRIANGLE is also EQUILATERAL, and the difference between the areas of the outer and inner Napoleon triangles equals the AREA of the original TRIANGLE (Wells 1991, p. 156).

Drawing the centers of one EQUILATERAL TRIANGLE inwards and two outwards gives a 30°-30°-120° TRIANGLE (Wells 1991, p. 156).



Napoleon's theorem has a very beautiful generalization in the case of externally constructed triangles: If SIMILAR triangles *of any shape* are constructed externally on a triangle such that each is rotated relative to its neighbors and *any* three corresponding points of these triangles are connected, the result is a triangle which is SIMILAR to the external triangles (Wells 1991, pp. 156–157).

Narcissistic Number

An n-DIGIT number which is the SUM of the nth POWERS of its DIGITS is called an n-narcissistic number, or sometimes an ARMSTRONG NUMBER or PERFECT DIGITAL INVARIANT (Madachy 1979). The smallest example other than the trivial 1-DIGIT numbers is

$$153 = 1^3 + 5^3 + 3^3. \qquad (1)$$

The series of smallest narcissistic numbers of n digits are 0, (none), 153, 1634, 54748, 548834, ... (Sloane's

A014576). Hardy (1993) wrote, "There are just four numbers, after unity, which are the sums of the cubes of their digits: $153 = 1^3 + 5^3 + 3^3$, $370 = 3^3 + 7^3 + 0^3$, $371 = 3^3 + 7^3 + 1^3$, and $407 = 4^3 + 0^3 + 7^3$. These are odd facts, very suitable for puzzle columns and likely to amuse amateurs, but there is nothing in them which appeals to the mathematician." The following table gives the generalization of these "unappealing" numbers to other POWERS (Madachy 1979, p. 164).

n	n-narcissistic numbers
1	0, 1, 2, 3, 4, 5, 6, 7, 8, 9
2	none
3	153, 370, 371, 407
4	1634, 8208, 9474
5	54748, 92727, 93084
6	548834
7	1741725, 4210818, 9800817, 9926315
8	24678050, 24678051, 88593477
9	146511208, 472335975, 534494836, 912985153
10	4679307774

A total of 88 NARCISSISTIC NUMBERS exist in base 10, as proved by D. Winter in 1985 and verified by D. Hoey. These numbers exist for only 1, 3, 4, 5, 6, 7, 8, 9, 10, 11, 14, 16, 17, 19, 20, 21, 23, 24, 25, 27, 29, 31, 32, 33, 34, 35, 37, 38, and 39 digits. It can easily be shown that base-10 n-narcissistic numbers can exist only for $n \leq 60$, since

$$n \cdot 9^n < 10^{n-1} \tag{2}$$

for $n > 60$. The largest base-10 narcissistic number is the 39-narcissistic

$$115132219018763992565095597973971522401. \tag{3}$$

A table of the largest known narcissistic numbers in various BASES is given by Pickover (1995). A tabulation of narcissistic numbers in various bases is given by (Corning).

A closely related set of numbers generalize the narcissistic number to n-DIGIT numbers which are the sums of *any* single POWER of their DIGITS. For example, 4150 is a 4-DIGIT number which is the sum of fifth POWERS of its DIGITS. Since the number of digits is not equal to the power to which they are taken for such numbers, they are *not* narcissistic numbers. The smallest numbers which are sums of *any* single positive power of their digits are 1, 2, 3, 4, 5, 6, 7, 8, 9, 153, 370, 371, 407, 1634, 4150, 4151, 8208, 9474, ... (Sloane's A023052), with powers 1, 1, 1, 1, 1, 1, 1, 1, 1, 3, 3, 3, 3, 4, 5, 5, 4, 4, ... (Sloane's A046074).

The smallest numbers which are equal to the nth powers of their digits for $n = 3$, 4, ..., are 153, 1634, 4150, 548834, 1741725, ... (Sloane's A003321). The n-digit numbers equal to the sum of nth powers of their digits (a finite sequence) are called ARMSTRONG NUMBERS or plus perfect number and are given by 1, 2, 3, 4, 5, 6, 7, 8, 9, 153, 370, 371, 407, 1634, 8208, 9474, 54748, ... (Sloane's A005188).

If the sum-of-kth-powers-of-digits operation applied iteratively to a number n eventually returns to n, the smallest number in the sequence is called a k-RECURRING DIGITAL INVARIANT.

The numbers that are equal to the sum of consecutive powers of their digits are given by 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 89, 135, 175, 518, 598, 1306, 1676, 2427, 2646798 (Sloane's A032799), e.g.,

$$2646798 = 2^1 + 6^2 + 4^3 + 6^4 + 7^5 + 9^6 + 8^7. \tag{4}$$

Nasik Square

PANMAGIC SQUARE

Nasty Knot

An UNKNOT which can only be unknotted by first increasing the number of crossings.

Natural Boundary

This entry contributed by JONATHAN DEANE

Consider a POWER SERIES in a complex variable z

$$g(z) = \sum_{n=0}^{\infty} a_n z^n \tag{1}$$

that is convergent within the OPEN DISK $C : |z| < R$. Convergence is limited to within C by the presence of at least one SINGULARITY on the BOUNDARY ∂C of C. If the singularities on C are so densely packed that ANALYTIC CONTINUATION cannot be carried out on a path that crosses C, then C is said to form a natural boundary for the function $g(z)$.

As an example, consider the function

$$f(z) = \sum_{n=0}^{\infty} z^{2^n} = z + z^2 + z^4 + \ldots \tag{2}$$

Then $f(z)$ formally satisfies the FUNCTIONAL EQUATION

$$f(z) = z + f(z^2). \tag{3}$$

The series (2) clearly converges within $C_1 : |z| < 1$. Now consider $z = 1$. Equation (3) tells us that $f(1) = 1 + f(1)$ which can only be satisfied if $f(1) = \infty$. Considering now $z = -1$, equation (3) becomes $f(-1) = -1 + \infty$ and hence $f(-1) = \infty$. Substituting z^2 for z in equation (3) then gives

$$f(z^2) = z^2 + f(z^4) = f(z) - z. \tag{4}$$

from which it follows that

$$f(z) = z + z^2 + f(z^4). \tag{5}$$

Now consider z equal to any of the fourth roots of unity, ± 1, $\pm i$, for example $z = -i$. Then $f(-i) = -i - 1 + f(1) = \infty$. Applying this procedure recursively shows that $f(z)$ is infinite for any z such that $z^{2^n} = 1$ with $n = 0, 1, 2, \ldots$. In any arc of the circle ∂C_1 of finite length there will therefore be an infinite number of points for which $f(z)$ is infinite and so C_1 constitutes a natural boundary for $f(z)$.

A function that has a natural boundary is said to be a LACUNARY FUNCTION.

See also BOUNDARY, LACUNARY FUNCTION

Natural Density

NATURAL INVARIANT

Natural Equation

A natural equation is an equation which specifies a curve independent of any choice of coordinates or

parameterization. The study of natural equations began with the following problem: given two functions of one parameter, find the SPACE CURVE for which the functions are the CURVATURE and TORSION.

Euler gave an integral solution for plane curves (which always have TORSION $\tau = 0$). Call the ANGLE between the TANGENT line to the curve and the x-AXIS ϕ the TANGENTIAL ANGLE, then

$$\phi = \int \kappa(s) ds, \tag{1}$$

where κ is the CURVATURE. Then the equations

$$\kappa = \kappa(s) \tag{2}$$

$$\tau = 0, \tag{3}$$

where τ is the TORSION, are solved by the curve with PARAMETRIC EQUATIONS

$$x = \int \cos\phi \, ds \tag{4}$$

$$y = \int \sin\phi \, ds. \tag{5}$$

The equations $\kappa = \kappa(s)$ and $\tau = \tau(s)$ are called the natural (or INTRINSIC) equations of the space curve. An equation expressing a plane curve in terms of s and RADIUS OF CURVATURE R (or κ) is called a CESÀRO EQUATION, and an equation expressing a plane curve in terms of s and ϕ is called a WHEWELL EQUATION.

Among the special planar cases which can be solved in terms of elementary functions are the CIRCLE, LOGARITHMIC SPIRAL, CIRCLE INVOLUTE, and EPICYCLOID. Enneper showed that each of these is the projection of a HELIX on a CONIC surface of revolution along the axis of symmetry. The above cases correspond to the CYLINDER, CONE, PARABOLOID, and SPHERE.

Natural Independence Phenomenon

A type of mathematical result which is considered by most logicians as more natural than the METAMATHEMATICAL incompleteness results first discovered by Gödel. Finite combinatorial examples include GOODSTEIN'S THEOREM, a finite form of RAMSEY'S THEOREM, and a finite form of KRUSKAL'S TREE THEOREM (Kirby and Paris 1982; Smorynski 1980, 1982, 1983; Gallier 1991).

See also GÖDEL'S INCOMPLETENESS THEOREM, GOODSTEIN'S THEOREM, KRUSKAL'S TREE THEOREM, RAMSEY'S THEOREM

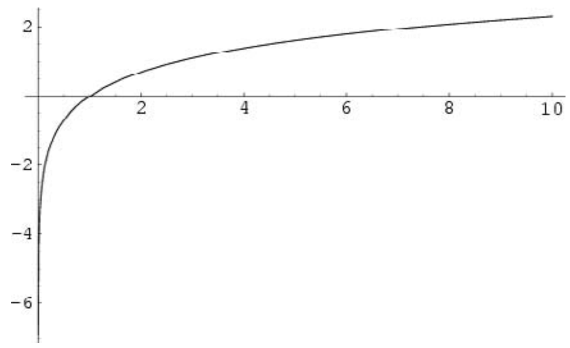
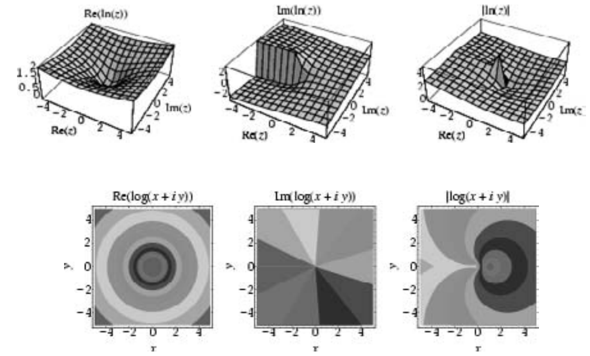
Natural Invariant

Let $\rho(x)dx$ be the fraction of time a typical dynamical ORBIT spends in the interval $[x, x+dx]$, and let $\rho(x)$ be normalized such that



$$\int_0^\infty \rho(x) dx = 1$$



over the entire interval of the map. Then the fraction the time an ORBIT spends in a finite interval $[a, b]$, is given by

$$\int_a^b \rho(x) dx.$$

The natural invariant is also called the INVARIANT DENSITY or NATURAL DENSITY.

Natural Logarithm

The LOGARITHM having base *E*, where

$$e = 2.718281828\ldots, \quad (1)$$

which can be defined

$$\ln x \equiv \int_1^x \frac{dt}{t} \quad (2)$$

for $x > 0$. The natural logarithm can also be defined by

$$\ln x = \lim_{x \to \infty} \left(x^{1/n} - 1\right)^n. \quad (3)$$

The symbol $\ln x$ is used in physics and engineering to denote the natural logarithm, while mathematicians commonly use the notation $\log x$. In this work, $\ln x = \log_e x$ denotes a natural logarithm, whereas $\log x = \log_{10} x$ denotes the COMMON LOGARITHM. Common and natural logarithms can be expressed in terms of each other as

$$\ln x = \frac{\log_{10} x}{\log_{10} e} \quad (4)$$

$$\log_{10} x = \frac{\ln x}{\ln 10}. \quad (5)$$

The natural logarithm is especially useful in CALCULUS because its DERIVATIVE is given by the simple equation

$$\frac{d}{dx} \ln x = \frac{1}{x}, \quad (6)$$

whereas logarithms in other bases have the more complicated DERIVATIVE

$$\frac{d}{dx} \log_b x = \frac{1}{x \ln b}. \quad (7)$$

The natural logarithm can be analytically continued to COMPLEX NUMBERS as

$$\ln z \equiv \ln|z| + i \arg(z), \quad (8)$$

where $|z|$ is the MODULUS and $\arg(z)$ is the ARGUMENT

The MERCATOR SERIES

$$\ln(1+x) = x - \tfrac{1}{2}x^2 + \tfrac{1}{3}x^3 - \ldots \quad (9)$$

gives a TAYLOR SERIES for the natural logarithm.

CONTINUED FRACTION representations of logarithmic functions include

$$\ln(1+x) = \cfrac{x}{1 + \cfrac{1^2 x}{2 + \cfrac{1^2 x}{3 + \cfrac{2^2 x}{4 + \cfrac{2^2 x}{5 + \cfrac{3^2 x}{6 + \cfrac{3^2 x}{7 + \ldots}}}}}}} \quad (10)$$

$$\ln\left(\frac{1+x}{1-x}\right) = \cfrac{2x}{1 - \cfrac{x^2}{3 - \cfrac{4x^2}{5 - \cfrac{9x^2}{7 - \cfrac{16x^2}{9 - \ldots}}}}} \quad (11)$$

For a COMPLEX NUMBER *z*, the natural logarithm satisfies

$$\ln z = \ln\left[re^{i(\theta + 2n\pi)}\right] = \ln r + i(\theta + 2n\pi) \quad (12)$$

$$PV(\ln z) = \ln r + i\theta, \quad (13)$$

where PV is the PRINCIPAL VALUE.

Some special values of the natural logarithm are

$$\ln 1 = 0 \quad (14)$$

$$\ln 0 = -\infty \quad (15)$$

$$\ln(-1) = \pi i \quad (16)$$

$$\ln(\pm i) = \pm\tfrac{1}{2}\pi i. \quad (17)$$

An identity for the natural logarithm of 2 discovered using the PSLQ ALGORITHM is

$$(\ln 2)^2 = 2\sum_{i=1}^{\infty} \frac{p_i}{2^i i^2} \quad \{p_i\} = \{\overline{2, -10, -7, -10, 2, -1}\}, \quad (18)$$

where $\{p_i\}$ is given by the periodic sequence obtained by appending copies of $\{2, -10, -7, -10, 2, -1\}$ (in other words, $p_i \equiv p_{[(i-1) \pmod 6]+1}$ for $i > 6$) (Bailey *et al.* 1995, Bailey and Plouffe).

Natural Measure

$\mu_i(\epsilon)$, sometimes denoted $P_i(\epsilon)$, is the probability that element i is populated, normalized such that

$$\sum_{i=1}^{N} \mu_i(\epsilon) = 1.$$

See also Information Dimension, q-Dimension

Natural Norm

Let $\|z\|$ be a vector norm of a vector **z** *such that*

$$\|\mathsf{A}\| = \max_{\|\mathbf{z}\|=1} \|\mathsf{A}\mathbf{z}\|.$$

Then $\|\mathsf{A}\|$ is a matrix norm which is said to be the natural norm induced (or subordinate) to the vector norm $\|\mathbf{z}\|$. For any natural norm,

$$\|\mathsf{I}\| = 1,$$

where I is the identity matrix. The natural matrix norms induced by the L1-norm, L2-norm, and L-infinity-norm are called the maximum absolute column sum norm, spectral norm, and maximum absolute row sum norm, respectively.

See also L1-Norm, L2-Norm, Matrix Norm, Maximum Absolute Column Sum Norm, Spectral Norm, Vector Norm

Natural Number

A positive integer 1, 2, 3, ... (Sloane's A000027). The set of natural numbers is denoted N or Z+. Unfortunately, 0 is sometimes also included in the list of "natural" numbers (Bourbaki 1968, Halmos 1974), and there seems to be no general agreement about whether to include it. In fact, Ribenboim (1996) states "Let P be a set of natural numbers; whenever convenient, it may be assumed that $0 \in P$."

Due to lack of standard terminology, the following terms are recommended in preference to "counting number," "natural number," and "whole number."

set	name	symbol
..., -2, -1, 0, 1, 2, ...	integers	Z
1, 2, 3, 4, ...	positive integers	Z+
0, 1, 2, 3, 4, ...	nonnegative integers	Z*
0, -1, -2, -3, -4, ...	nonpositive integers	
-1, -2, -3, -4, ...	negative integers	Z-

nc

JACOBI ELLIPTIC FUNCTIONS

N-Cluster

A LATTICE POINT configuration with no three points COLLINEAR and no four CONCYCLIC. An example is the 6-cluster (0, 0), (132, −720), (546, −272), (960, −720), (1155, 540), (546, 1120). Call the RADIUS of the smallest CIRCLE centered at one of the points of an N-cluster which contains all the points in the N-cluster the EXTENT. Noll and Bell (1989) found 91 nonequivalent prime 6-clusters of EXTENT less than 20937, but found no 7-clusters.

nd

JACOBI ELLIPTIC FUNCTIONS

Near Noble Number

A REAL NUMBER $0<\nu<1$ whose CONTINUED FRACTION is periodic, and the periodic sequence of terms is composed of a string of 1s followed by an INTEGER $n>1$,

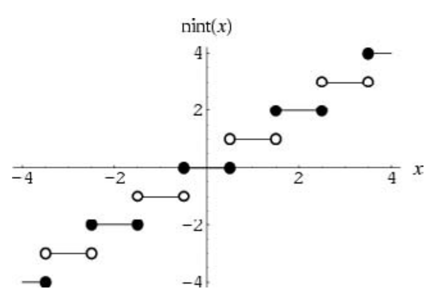
$$\nu=[\overline{\underbrace{1,1,\ldots,1}_{p},n}]. \tag{1}$$

This can be written in the form

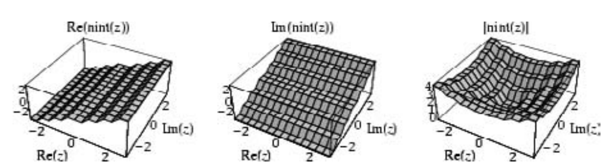
$$\nu=[\underbrace{1,1,\ldots,1}_{p},n,\nu^{-1}], \tag{2}$$

which can be solved to give

$$\nu=\frac{1}{2}n\left(\sqrt{1+4\frac{\mathrm{n}F_{p-1}+F_{p-2}}{n^2F_p}}-1\right), \tag{3}$$



where F_n is a FIBONACCI NUMBER. The special case $n=2$ gives



$$\nu=\sqrt{\frac{F_{p+2}}{F_p}}-1. \tag{4}$$

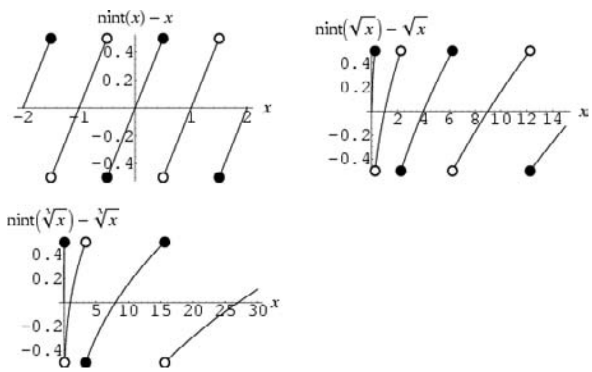
Nearest Integer Function



The nearest integer function `nint(x)` of x, illu-

strated above and also called nint or the round function, is defined such that $[x]$ is the INTEGER closest to x. Since this definition is ambiguous for half-integers, the additional rule that half-integers are always rounded to even numbers is usually added in order to avoid statistical biasing. For example, $[1.5]=2$, $[2.5]=2$, $[3.5]=4$, $[4.4]=4$, etc. This convention is followed in the C `math.h` library function `rint`, as well as in *Mathematica*, where the nearest integer function is implemented as `Round`$[x]$.

Although the notation $\lceil x \rfloor$ is sometimes used to denote the nearest integer function (Hastad *et al.* 1989), this notation is rather cumbersome and is not recommended. Also note that while $[x]$ is used to denote the nearest integer function in this work, $[x]$ is also commonly used to denote the FLOOR FUNCTION $\lfloor x \rfloor$.

The plots above illustrate $x^{1/n} - [x^{1/n}]$ for small n.

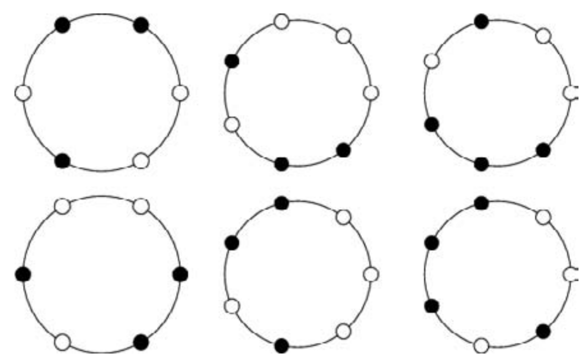
Necklace

In the technical COMBINATORIAL sense, an a-ary necklace of length n is a string of n characters, each of a possible types. Rotation is ignored, in the sense that $b_1 b_2 \ldots b_n$ is equivalent to $b_k b_{k+1} \ldots b_n b_1 b_2 \ldots b_{k-1}$ for any k.

In FIXED necklaces, reversal of strings is respected, so they represent circular collections of beads in which the necklace may not be picked up out of the PLANE (i.e., opposite orientations are not considered equivalent). The number of fixed necklaces of length n composed of a types of beads $N(n,a)$ is given by

$$N(n,a) = \frac{1}{n} \sum_{i=1}^{\nu(n)} \phi(d_i) a^{n/d_i}, \quad (1)$$



where d_i are the DIVISORS of n with $d_1 \equiv 1$, d_2, ..., $d_\nu(n) \equiv n$, $\nu(n)$ is the number of DIVISORS of n, and $\phi(x)$ is the TOTIENT FUNCTION.

For FREE necklaces, opposite orientations (MIRROR IMAGES) are regarded as equivalent, so the necklace *can* be picked up out of the PLANE and flipped over. The number $N'(n,a)$ of such necklaces composed of n beads, each of a possible colors, is given by

$$N'(n,a) = \frac{1}{2n} \times \begin{cases} \sum_{i=1}^{\nu(n)} \phi(d_i) a^{n/d_i} + n a^{(n+1)/2} & \text{for } n \text{ odd} \\ \sum_{i=1}^{\nu(n)} \phi(di) a^{n/d_i} + \frac{1}{2} n (1+a) a^{n/2} & \text{for } n \text{ even.} \end{cases}$$

For $a = 2$ and $n = p$ an ODD PRIME, this simplifies to

$$N'(p,2) = \frac{2^{p-1} - 1}{p} + 2^{(p-1)/2} + 1.$$

A table of the first few numbers of necklaces for $a = 2$ and $a = 3$ follows. Note that $N(n,2)$ is larger than $N'(n,2)$ for $n \geq 6$. For $n = 6$, the necklace 110100 is inequivalent to its MIRROR IMAGE 0110100, accounting for the difference of 1 between $N(6,2)$ and $N'(6,2)$. Similarly, the two necklaces 0010110 and 0101110 are inequivalent to their reversals, accounting for the difference of 2 between $N(7,2)$ and $N'(7,2)$.

Needle

BUFFON-LAPLACE NEEDLE PROBLEM, BUFFON'S NEEDLE PROBLEM, KAKEYA NEEDLE PROBLEM

Negabinary

The negabinary representation of a number n is given by the coefficients $a_n a_{n-1} \ldots a_1 a_0$ in

$$n = \sum_{i=0} a_i(-2)^i = \ldots + a_2(-2)^2 + a_1(-2)^1 + a_0(-2)^0,$$

where $a_i = 0, 1$. Conversion of n to negabinary can be done using the *Mathematica* code

```
Negabinary[n_Integer] := Module[{t = (2/3)(4^Floor[Log[4, Abs[n] + 1] + 2] - 1)},
IntegerDigits[BitXor[n + t, t], 2]]
```

The following table gives the negabinary representations for the first few integers (A039724).

n	negabinary	n	negabinary
1	1	11	11111
2	110	12	11100
3	111	13	11101
4	100	14	10010
5	101	15	10011
6	11010	16	10000
7	11011	17	10001
8	11000	18	10110
9	11001	19	10111
10	11110	20	10100

If these numbers are interpreted as binary numbers and converted to decimal, their values are 1, 6, 7, 4, 5, 26, 27, 24, 25, 30, 31, 28, 29, 18, 19, 16, ... (Sloane's A005351). The numbers having the same representation in BINARY and negabinary are members of the MOSER-DE BRUIJN SEQUENCE, 0, 1, 4, 5, 16, 17, 20, 21, 64, 65, 68, 69, 80, 81, ... (Sloane's A000695).

Negadecimal

The negadecimal representation of a number n is given by the coefficients $a_n a_{n-1} \ldots a_1 a_0$ in

$$n = \sum_{i=0} a_i(-10)^i = \ldots a_2(-10)^2 + a_1(-10)^1 + a_0(-10)^0,$$

where $a_i = 0, 1, \ldots, 9$. The following table gives the negabinary representations for the first few integers (A039723).

n	negadecimal	n	negadecimal	n	negadecimal
1	1	11	191	21	181
2	2	12	192	22	182
3	3	13	193	23	183
4	4	14	194	24	184
5	5	15	195	25	185
6	6	16	196	26	186
7	7	17	197	27	187
8	8	18	198	28	188
9	9	19	199	29	189
10	190	20	180	30	170

The numbers having the same DECIMAL and negadecimal representations are those which are sums of distinct powers of 100: 1, 2, 3, 4, 5, 6, 7, 8, 9, 100, 101, 102, 103, 104, 105, 106, 107, 108, 109, 200, ... (Sloane's A051022).

Negation

The operation of interchanging true and false in a logical statement. The negation of A is often called "NOT-A," and can be denoted $!A$, or with the NEGATION SIGN $\neg$, so not-A is written $\neg A$.

Note that in computer languages such as `C`, `perl`, and *Mathematica*, not-A is denoted $!A$. In FORTRAN, not-A is written `.not.A`, where A is a variable of `logical` type.

See also NEGATION SIGN, NOT

Negation Sign

The symbol $\neg$ used to denote the NEGATION operation ("NOT") in symbolic logic, also called "logical not."

See also NOT

Negative Binomial Distribution

Also known as the PASCAL DISTRIBUTION and PÓLYA DISTRIBUTION. The probability of $r-1$ successes and x failures in $x+r-1$ trials, and success on the $(x+r)$th trial is

$$p\left[\binom{x+r-1}{r-1}p^{r-1}(1-p)^{[(x+r-1)-(r-1)]}\right] = \left[\binom{x+r-1}{r-1}p^{r-1}(1-p)^x\right]p = \binom{x+r-1}{r-1}p^r(1-p)^x, \quad (1)$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT. Let

$$P=\frac{1-p}{p} \quad (2)$$

$$Q=\frac{1}{p}. \quad (3)$$

The CHARACTERISTIC FUNCTION is given by

$$\phi(t)=\left(Q-Pe^{it}\right)^{-r}, \quad (4)$$

and the MOMENT-GENERATING FUNCTION by

$$M(t)=\langle e^{tz}\rangle=\sum_{x=0}^{\infty}e^{tx}\binom{x+r-1}{r-1}p^r(1-p)^x, \quad (5)$$

but, since $\binom{N}{n}=\binom{N}{N-m}$,

$$M(t)=p^r\sum_{x=0}^{\infty}\binom{x+r-1}{x}[(1-p)e^t]^x = p^r[1-(1-p)e^t]^{-r} \quad (6)$$

$$M'(t)=p^r(-r)[1-(1-p)e^t]^{-r-1}(p-1)e^t = p^r(1-p)r[1-(1-p)e^t]^{-r-1}e^t \quad (7)$$

$$M''(t)=(1-p)rp^r(1-e^t+pe^t)^{-r-2} \times(-1-e^tr+e^tpr)e^t \quad (8)$$

$$M'''(t)=(1-p)rp^r(1-e^t+e^tp)^{-r-3} \times[1+e^t(1-p+3r-3pr)+r^2e^{2t}(1-p)^2]e^t. \quad (9)$$

The MOMENTS about zero $K(u)$ are therefore

$$\mu_1'=\mu=\frac{r(1-p)}{p}=\frac{rq}{p} \quad (10)$$

$$\mu_2' = \frac{r(1-p)[1-r(p-1)]}{p^2} = \frac{rq(1-rq)}{p^2} \quad (11)$$

$$\mu_3' = \frac{(1-p)r(2-p+3r-3pr+r^2-2pr^2+p^2r^2)}{p^3} \quad (12)$$

$$\mu_4' = \frac{(-1+p)r(-6+6p-p^2-11r+15pr-4p^2r-6r^2}{p^4} + \frac{12pr^2-6p^2r^2-r^3+3pr^3-3p^2r^3+p^3r^3)}{p^4}. \quad (13)$$

(Beyer 1987, p. 487, apparently gives the MEAN incorrectly.) The MOMENTS about the mean are

$$\mu_2 = \sigma^2 = \frac{r(1-p)}{p^2} \quad (14)$$

$$\mu_3 = \frac{r(2-3p+p^2)}{p^3} = \frac{r(p-1)(p-2)}{p^3} \quad (15)$$

$$\mu_4 = \frac{r(1-p)(6-6p+p^2+3r-3pr)}{p^4}. \quad (16)$$

The MEAN, VARIANCE, SKEWNESS and KURTOSIS are then

$$\mu = \frac{r(1-p)}{p} \quad (17)$$

$$\gamma_1 = \frac{\mu_3}{\sigma^3} = \frac{r(p-1)(p-2)}{p^3}\left[\frac{p^2}{r(1-p)}\right]^{3/2} = \frac{r(2-p)(1-p)}{p^3}\,\frac{p^3}{r(1-p)\sqrt{1-p}} = \frac{2-p}{\sqrt{r(1-p)}} \quad (18)$$

$$\gamma_2 = \frac{\mu_4}{\sigma^4} - 3 = \frac{-6+6p-p^2-3r+3pr}{(p-1)r}, \quad (19)$$

which can also be written

$$\mu = nP \quad (20)$$

$$\mu_2 = nPQ \quad (21)$$

$$\gamma_1 = \frac{Q+P}{\sqrt{rPQ}} \quad (22)$$

$$\gamma_2 = \frac{1+6PQ}{rPQ} - 3. \quad (23)$$

The first CUMULANT is

$$\kappa_1 = nP, \quad (24)$$

and subsequent CUMULANTS are given by the RECURRENCE RELATION

$$\kappa_{r+1} = PQ\frac{d\kappa_r}{dQ}. \quad (25)$$

Negative Binomial Series

The SERIES which arises in the BINOMIAL THEOREM for NEGATIVE integer n,

$$(x+a)^{-n} = \sum_{k=0}^{\infty}\binom{-n}{k}x^k a^{-n-k} = \sum_{k=0}^{\infty}(-1)^k\binom{n+k-1}{k}x^k a^{-n-k}.$$

For $a = 1$, the negative binomial series simplifies to

$$(x+1)^{-n} = 1 - nx + \tfrac{1}{2}n(n+1)x^2 - \tfrac{1}{6}n(n+1)(n+2) + \ldots.$$

See also BINOMIAL SERIES, BINOMIAL THEOREM

Negative Definite Matrix

A negative definite matrix is a HERMITIAN MATRIX all of whose EIGENVALUES are negative.

Negative Integer

Z_-

Negative Likelihood Ratio

The term negative likelihood ratio is also used (especially in medicine) to test nonnested complementary hypotheses as follows,

$$\mathrm{NLR} = \frac{[\text{true negative rate}]}{[\text{false negative rate}]} = \frac{[\text{specificity}]}{1-[\text{sensitivity}]}.$$

See also LIKELIHOOD RATIO, SENSITIVITY, SPECIFICITY

Negative Pedal Curve

Given a curve C and O a fixed point called the PEDAL POINT, then for a point P on C, draw a LINE PERPENDICULAR to OP. The ENVELOPE of these LINES as P describes the curve C is the negative pedal of C.

Neighborhood

The word neighborhood is a word with many different levels of meaning in mathematics. One of the most general concepts of a neighborhood of a point $\mathbf{x} \in \mathbb{R}^n$ (also called an epsilon-neighborhood or infinitesimal OPEN SET) is the set of points inside an n-BALL with center $\mathbf{x}$ and RADIUS $\epsilon > 0$.

See also BALL, OPEN SET

Neile's Parabola

The solid curve in the above figure which is the EVOLUTE of the PARABOLA (dashed curve). In CARTESIAN COORDINATES,

$$y = \tfrac{3}{4}(2x)^{2/3} + \tfrac{1}{2}$$

Neile's parabola is also called the SEMICUBICAL PARABOLA, and was discovered by William Neile in 1657. It was the first nontrivial ALGEBRAIC CURVE to have its ARC LENGTH computed. Wallis published the method in 1659, giving Neile the credit (MacTutor Archive).

See also PARABOLA EVOLUTE

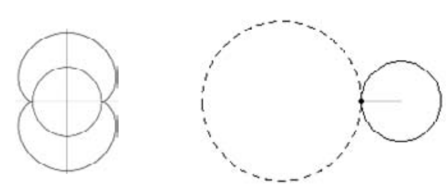
Nelder-Mead Method



A direct search method of optimization that works moderately well for stochastic problems. It is based on evaluating a function at the vertices of a SIMPLEX, then iteratively shrinking the simplex as better points are found until some desired bound is obtained (Nelder and Mead 1965).

See also STOCHASTIC OPTIMIZATION

Nephroid

The 2-CUSPED EPICYCLOID is called a nephroid. Since $n = 2$, $a = b/2$, and the equation for r^2 in terms of the parameter ϕ is given by EPICYCLOID equation

$$r^2 = \frac{a^2}{n^2}\left[(n^2+2n+2) - 2(n+1)\cos(n\phi)\right] \tag{1}$$

with $n = 2$,

$$r^2 = \frac{a^2}{2^2}\left[(2^2+2\cdot 2+2) - 2(2+1)\cos(2\phi)\right]$$

$$= \tfrac{1}{4}a^2[10 - 6\cos(2\phi)] = \tfrac{1}{2}a^2[5 - 3\cos(2\phi)], \tag{2}$$

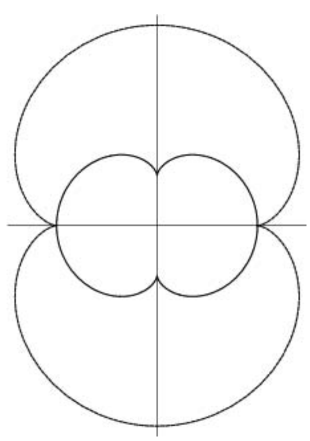
where

$$\tan\theta = \frac{3\sin\phi - \sin(3\phi)}{3\cos\phi - \cos(3\phi)}. \tag{3}$$

This can be written

$$\left(\frac{r}{2a}\right)^{2/3} = \left[\sin\left(\tfrac{1}{2}\theta\right)\right]^{2/3} + \left[\cos\left(\tfrac{1}{2}\theta\right)\right]^{2/3}. \tag{4}$$

The PARAMETRIC EQUATIONS are



$$x = a[3\cos t - \cos(3t)] \tag{5}$$

$$y = a[3\sin t - \sin(3t)]. \tag{6}$$

The Cartesian equation is

$$(x^2+y^2-4a^2)^3 = 108a^4y^2. \tag{7}$$

The name nephroid means "kidney shaped" and was first used for the two-cusped EPICYCLOID by Proctor in 1878 (MacTutor Archive). The nephroid has ARC LENGTH $24a$ and AREA $12\pi^2a^2$. The CATACAUSTIC for rays originating at the CUSP of a CARDIOID and reflected by it is a nephroid. Huygens showed in 1678 that the nephroid is the CATACAUSTIC of a CIRCLE when the light source is at infinity. He published this fact in *Traité de la luminère* in 1690 (MacTutor Archive).

The nephroid can be generated as the ENVELOPE of circles centered on a given circle and tangent to one of the circle's diameters (Wells 1991).

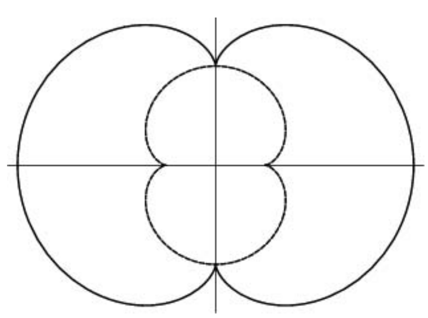
Nephroid Evolute

The EVOLUTE of the NEPHROID given by

$$x = \tfrac{1}{2}[3\cos t - \cos(3t)]$$

$$y = \tfrac{1}{2}[3\sin t - \sin(3t)]$$



is given by

$$x = \cos^3 t$$

$$y = \tfrac{1}{4}[3\sin t + \sin(3t)],$$

which is another NEPHROID.

Nephroid Involute

The INVOLUTE of the NEPHROID given by

$$x = \tfrac{1}{2}[3\cos t - \cos(3t)]$$

$$y = \tfrac{1}{2}[3\sin t - \sin(3t)]$$

beginning at the point where the nephroid cuts the Y-

AXIS is given by

$$x = 4\cos^3 t$$
$$y = 3\sin t + \sin(3t),$$

another NEPHROID. If the INVOLUTE is begun instead at the CUSP, the result is CAYLEY'S SEXTIC.

Néron-Severi Group

Let V be a complete normal VARIETY, and write $G(V)$ for the group of divisors, $G_n(V)$ for the group of divisors numerically equal to 0, and $G_a(V)$ the group of divisors algebraically equal to 0. Then the finitely generated QUOTIENT GROUP $NS(V) = G(V)/G_a(V)$ is called the Néron-Severi group.

Nested Hypothesis

Let S be the set of all possibilities that satisfy HYPOTHESIS H, and let S' be the set of all possibilities that satisfy HYPOTHESIS H'. Then H' is a nested hypothesis within H IFF $S' \subset S$, where $\subset$ denotes the PROPER SUBSET.

See also LOG LIKELIHOOD PROCEDURE

Nested Radical

Expressions OF THE FORM

$$\lim_{k\to\infty} x_0 + \sqrt{x_1 + \sqrt{x_2 + \sqrt{\ldots + x_k}}}.$$

Herschfeld (1935) proved that a nested radical of REAL NONNEGATIVE terms converges IFF $(x_n)^{2^{-n}}$ is bounded. He also extended this result to arbitrary POWERS (which include continued square roots and CONTINUED FRACTIONS as well), a result is known as HERSCHFELD'S CONVERGENCE THEOREM.

Nested radicals appear in the computation of PI,

$$\frac{2}{\pi} = \sqrt{\tfrac{1}{2}}\sqrt{\tfrac{1}{2}+\tfrac{1}{2}\sqrt{\tfrac{1}{2}}}\sqrt{\tfrac{1}{2}+\tfrac{1}{2}\sqrt{\tfrac{1}{2}+\tfrac{1}{2}\sqrt{\tfrac{1}{2}}}}\cdots \tag{1}$$

in TRIGONOMETRICAL values of COSINE and SINE for arguments OF THE FORM $\pi/2^n$, e.g.,

$$\sin\left(\frac{\pi}{8}\right) = \tfrac{1}{2}\sqrt{2-\sqrt{2}} \tag{2}$$

$$\cos\left(\frac{\pi}{8}\right) = \tfrac{1}{2}\sqrt{2+\sqrt{2}} \tag{3}$$

$$\sin\left(\frac{\pi}{16}\right) = \tfrac{1}{2}\sqrt{2-\sqrt{2+\sqrt{2}}} \tag{4}$$

$$\cos\left(\frac{\pi}{16}\right) = \tfrac{1}{2}\sqrt{2+\sqrt{2+\sqrt{2}}}, \tag{5}$$

and in the computation of the GOLDEN RATIO,

$$\phi = \sqrt{1+\sqrt{1+\sqrt{1+\sqrt{1+\ldots}}}}. \tag{6}$$

There are a number of general formula for nested radicals (Wong and McGuffin). For example,

$$x = \sqrt{(1-q)x^n + qx^{n-1}\sqrt{(1-q)x^n + qx^{n-1}\sqrt{\ldots}}} \tag{7}$$

which gives as special cases

$$\frac{b + \sqrt{b^2 + 4a}}{2} = \sqrt{a + b\sqrt{a + b\sqrt{a + b\sqrt{\ldots}}}} \tag{8}$$

$(n = 2,\ q = 1 - a/x^2,\ x = b/q)$,

$$x = \sqrt{x^{n-1}\sqrt{x^{n-1}\sqrt{x^{n-1}\sqrt{\ldots}}}} \tag{9}$$

$(q = 1)$, and

$$x = \sqrt{x\sqrt{x\sqrt{x\sqrt{x\sqrt{\ldots}}}}} \tag{10}$$

$(q = 1, n = 2)$. Equation (7) gives rise to

$$q^{(n^k-1/(n-1)}x^{n^j}$$
$$= \sqrt{q^{(n^{k+1}-n)/(n-1)}(1-q)x^{n^{j+1}} + \ldots}$$
$$\overline{\ldots + \sqrt{q^{(n^{k+2}-n)/(n-1)}(1-q)x^{n^{j+2}} + \sqrt{\ldots}}}, \tag{11}$$

which gives the special case for $q = 1/2$, $n = 2$, $x = 1$, and $k = -1$,

$$\sqrt{2} = \sqrt{\frac{2}{2^{2^0}} + \sqrt{\frac{2}{2^{2^1}} + \sqrt{\frac{2}{2^{2^2}} + \sqrt{\frac{2}{2^{2^3}} + \sqrt{\frac{2}{2^{2^4}} + \ldots}}}}} \tag{12}$$

Ramanujan discovered

$$x + n + a$$
$$= \sqrt{ax + (n+a)^2 + x\sqrt{a(x+n) + (n+a)^2 + \ldots}}$$

$$\ldots + (x+n)\sqrt{a(x+2n) + (n+a)^2 + (x+2n)\sqrt{\ldots}},$$

which gives the special cases

$$x+1 = \sqrt{1 + x\sqrt{1 + (x+1)\sqrt{1 + (x+2)\sqrt{1+\ldots}}}}, \quad (13)$$

for $a = 0$, $n = 1$, and

$$3 = \sqrt{1 + 2\sqrt{1 + 3\sqrt{1 + 4\sqrt{1 + 5\sqrt{\ldots}}}}} \quad (14)$$

for $a = 0$, $n = 1$, and $x = 2$.

For a nested radical OF THE FORM

$$x = \sqrt{n + \sqrt{n + \sqrt{n + \ldots}}} \quad (15)$$

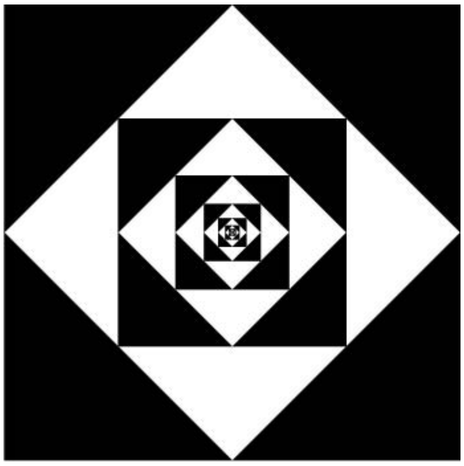
to be equal a given REAL NUMBER x, it must be true that

$$x = \sqrt{n + \sqrt{n + \sqrt{n + \ldots}}} = \sqrt{n + x}, \quad (16)$$

so

$$x^2 = n + x \quad (17)$$

and



$$x = \tfrac{1}{2}\left(1 + \sqrt{4n+1}\right). \quad (18)$$

Net

The word net has several meanings in mathematics. It refers to a plane diagram in which the EDGES of a POLYHEDRON are shown. All convex POLYHEDRA have nets, but not all concave polyhedra do (the constituent POLYGONS can overlap one another when a concave POLYHEDRON is flattened out). The GREAT DODECAHEDRON and STELLA OCTANGULA are examples of a concave polyhedron which have nonself-intersecting nets.

A corrected and concatenated version of the Bell Laboratories netlib polyhedron database has been prepared by Weisstein, together with *Mathematica* code to access analytic vertex coordinates and plot nets for all Platonic and Archimedean solids and their duals, as well as the Johnson solids. K. Fukuda has written routines which can unfold convex polyhedra into a planar net.

The term net also has a technical meaning as a generalization of a SEQUENCE, in which context it is also known as a Moore-Smith sequence. In this

context, nets is used in general topology and ANALYSIS to imbue non-metrizable topological spaces with convergence properties. This artifice is needed only in spaces which are not FIRST-COUNTABLE, since sequences alone provide an adequate way of dealing with CONTINUITY for FIRST-COUNTABLE SPACES. Nets are used in the study of the RIEMANN INTEGRAL. Formally, a net of a set S is a mapping from a DIRECTED SET D into S.

Network

A GRAPH or DIRECTED GRAPH together with a function which assigns a positive real number to each edge (Harary 1994, p. 52).

See also GRAPH, NETWORK FLOW, SINK (DIRECTED GRAPH), SMITH'S NETWORK THEOREM, SOURCE

References

Harary, F. *Graph Theory.* Reading, MA: Addison-Wesley, 1994.

Network Flow

The network flow problem considers a graph G with a set of sources S and sinks T and for which each edge has an assigned capacity (weight), and then asks to find the maximum flow that can be routed from S to T while respecting the given edge capacities. The network flow problem can be solved in time $\mathcal{O}(n^3)$ (Edmonds and Karp 1972; Skiena 1990, p. 237). It has been implemented as `NetworkFlow[`*g*, *source*, *sink*`]` in the *Mathematica* add-on package `DiscreteMath'Combinatorica'` (which can be loaded with the command `<<DiscreteMath'`) and `NetworkFlowEdges[`*g*, *source*, *sink*`]` in the *Mathematica* add-on package `DiscreteMath'Combinatorica'` (which can be loaded with the command `<<DiscreteMath'`).

Neuberg Center

The center of a NEUBERG CIRCLE.

See also NEUBERG CIRCLE

Neuberg Circle

The LOCUS of the VERTEX A_1 of a TRIANGLE on a given base A_2A_3 and with a given BROCARD ANGLE ω is a CIRCLE (actually two circles, one on either side of A_2A_3) known as the Neuberg circle. From the center N_1, the base A_2A_3 subtends the ANGLE 2ω. The equation of the circle can be found by taking the base as (0, 0), (0, a_1) and solving

$$x^2 + y^2 = a_3^2 \tag{1}$$

$$(x - a_1)^2 + y^2 = a_2^2 \tag{2}$$

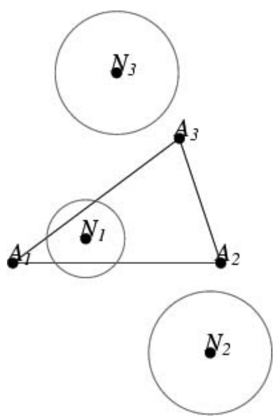
while eliminating a_2 and a_3 using

$$\cos \omega = \frac{a_1^2 + a_2^2 + a_3^3}{4\Delta}, \tag{3}$$

where Δ is the area of the triangle $\Delta A_1A_2A_3$. Solving for x gives

$$x=\frac{1}{2}\left(a_1 \pm \sqrt{\pm 4a_1 y \cot\omega - 4y^2 - 3a_1^2}\right), \quad (4)$$

and squaring and completing the square results in



$$\left(x-\frac{1}{2}a_1\right)^2+\left(y\pm\frac{1}{2}a_1\cot\omega\right)^2=\frac{1}{4}a_1(\cot^2\omega-3) \quad (5)$$

Therefore, the Neuberg circle N_1 on this edge has center

$$N_1=\left(\frac{1}{2}a_1, \pm\frac{1}{2}a_1\cot\omega\right) \quad (6)$$

(sometimes called the NEUBERG CENTER), and RADIUS

$$r=\frac{1}{2}a_1\sqrt{\cot^2\omega-3}.$$

The same procedure can be repeated for the other two sides of a TRIANGLE resulting in three Neuberg circles (with another corresponding three on opposite sides of the edges). The TRIANGLE connecting the three NEUBERG CENTERS is called the NEUBERG TRIANGLE.

On one side of a given line taken as a base, it is possible to construct six triangles directly or inversely similar to a given SCALENE TRIANGLE, and the vertices of these triangles lie on their common Neuberg circles (Johnson 1929, p. 289).

Neuberg Triangle

The TRIANGLE $\Delta N_1N_2N_3$ formed by joining a set of three NEUBERG CENTERS (i.e., centers of the NEUBERG CIRCLES) obtained from the edges of a given triangle $\Delta A_1A_2A_3$ (left figure). The CENTROID G_N of $\Delta N_1N_2N_3$ is coincident with the CENTROID G_A of $\Delta A_1A_2A_3$ (Johnson 1929, p. 288; right figure).

The lines A_1N_1, A_2N_2, and A_3N_3 are concurrent at a point T which Johnson (1929, p. 288) claims (apparently incorrectly) is the TARRY POINT.

Neumann Function

BESSEL FUNCTION OF THE SECOND KIND

Neumann Polynomial

Polynomials $O_n(x)$ that can be defined by the sum

$$O_n(x) = \frac{1}{4}\sum_{k=0}^{\lfloor n/2 \rfloor} \frac{n(n-k-1)!}{k!}\left(\tfrac{1}{2}x\right)^{2k-n-1} \quad (1)$$

for $n \geq 1$, where $\lfloor x \rfloor$ is the FLOOR FUNCTION. They obey the RECURRENCE RELATION

$$O_n(x) = -\frac{n}{n-2}O_{n-2}(x) + \frac{2n}{x}O_{n-1}(x) + \frac{2(n-1)}{(n-2)x}\sin^2\left[\tfrac{1}{2}(n-1)\pi\right] \quad (2)$$

for $n \geq 3$. They have the integral representation

$$O_n(x) = \int_0^\infty \frac{\left(u+\sqrt{u^2+x^2}\right)^n + \left(u-\sqrt{u^2+x^2}\right)^n}{2x^{n+1}} e^{-u}\,du, \quad (3)$$

and the generating function

$$\frac{1}{x-\xi} = J_0(\xi)x^{-1} + 2\sum_{n=1}^\infty J_n(\xi)O_n(x) \quad (4)$$

(Gradshteyn and Ryzhik 2000, p. 990), and obey the NEUMANN DIFFERENTIAL EQUATION.

The first few Neumann polynomials are given by

$$O_0(x) = \frac{1}{x}$$

$$O_1(x) = \frac{1}{x^2}$$

$$O_2(x) = \frac{x^2+4}{x^3}$$

$$O_3(x) = \frac{3x^2+24}{x^4}$$

$$O_4(x) = \frac{x^4+16x^2+192}{x^5}$$

(A057869).

Neumann Series (Bessel Function)

A series OF THE FORM

$$\sum_{n=0}^\infty a_n J_{\nu+n}(z), \quad (1)$$

where ν is a REAL and $J_{\nu+n}(z)$ is a BESSEL FUNCTION OF THE FIRST KIND. Special cases are

$$z^\nu = 2^\nu\Gamma\left(\tfrac{1}{2}\nu+1\right)\sum_{n=0}^\infty \frac{\left(\tfrac{1}{2}z\right)^{\nu/2+n}}{n!}J_{\nu/2+n}(z), \quad (2)$$

where $\Gamma(z)$ is the GAMMA FUNCTION, and

$$\sum_{n=0}^\infty b_n z^{\nu+n} = \sum_{n=0}^\infty a_n\left(\tfrac{1}{2}z\right)^{(\nu+n)/2}J_{(\nu+n)/2}(z), \quad (3)$$

where

$$a_n \equiv \sum_{m=0}^{\lfloor n/2 \rfloor} \frac{2^{\nu+n-2m}\Gamma\left(\tfrac{1}{2}\nu+\tfrac{1}{2}n-m+1\right)}{m!}b_{n-2m}, \quad (4)$$

and $\lfloor x \rfloor$ is the FLOOR FUNCTION.

Neumann Series (Integral Equation)

A FREDHOLM INTEGRAL EQUATION OF THE SECOND KIND

$$\phi(x) = f(x) + \int_a^b K(x,t)\phi(t)\,dt \tag{1}$$

may be solved as follows. Take

$$\phi_0(x) \equiv f(x) \tag{2}$$

$$\phi_1(x) = f(x) + \lambda \int_a^b K(x,t)f(t)\,dt \tag{3}$$

$$\begin{aligned}\phi_2(x) = f(x) &+ \lambda \int_a^b K(x,t_1)f(t_1)\,dt_1 \\ &+ \lambda^2 \int_a^b \int_a^b K(x,t_1)K(t_1,t_2)f(t_2)\,dt_2\,dt_1\end{aligned} \tag{4}$$

$$\phi_n(x) = \sum_{i=0}^n \lambda^i u_i(x), \tag{5}$$

where

$$u_0(x) = f(x) \tag{6}$$

$$u_1(x) = \int_a^b K(x,t)f(t_1)\,dt_1 \tag{7}$$

$$u_2(x) = \int_a^b \int_a^b K(x,t_1)K(t_1,t_2)f(t_2)\,dt_2\,dt_1. \tag{8}$$

$$\begin{aligned}u_n(x) = \int_a^b \int_a^b \int_a^b &K(x,t_1)K(t_1,t_2)\cdots \\ &\times K(t_{n-1},t_n)f(t_n)\,dt_n \cdots dt_1.\end{aligned} \tag{9}$$

The Neumann series solution is then

$$\phi(x) = \lim_{n\to\infty} \phi_n(x) = \lim_{n\to\infty} \sum_{i=0}^n \lambda^i u_i(x). \tag{10}$$

Neusis Construction

A geometric construction, also called a VERGING CONSTRUCTION, which allows the classical GEOMETRIC CONSTRUCTION rules to be bent in order to permit sliding of a *marked* RULER. Using a Neusis construction, CUBE DUPLICATION, angle TRISECTION, and construction of the regular HEPTAGON are soluble. The CONCHOID OF NICOMEDES can also be used to perform many Neusis constructions (Johnson 1975). Conway and Guy (1996) give Neusis constructions for the 7-, 9-, and 13-gons which are based on angle TRISECTION.

Neville's Algorithm

An interpolation ALGORITHM which proceeds by first fitting a POLYNOMIAL P_k of degree 0 through the points (x_k, y_k) for $k = 0\ ...,\ n$, i.e., $P_k = y_k$. A second iteration is then performed in which P_{12} is fit through pairs of points, yielding P_{12}, P_{23}, ... The procedure is repeated, generating a "pyramid" of approximations until the final result is reached

$$\begin{array}{llll} P_1 & & & \\ & P_{12} & & \\ P_2 & & P_{123} & \\ & P_{23} & & P_{1234}. \\ P_3 & & P_{234} & \\ & P_{34} & & \\ P_4 & & & \end{array}$$

The final result is

$$P_{i(i+1)\cdots(i+m)} = \frac{(x - x_{i+m})P_{i(i+1)\cdots(i+m-1)}}{x_i - x_{i+m}} + \frac{(x_i - x)P_{(i+1)(i+2)\cdots(i+m)}}{x_i - x_{i+m}}.$$

Newcomb's Paradox

A paradox in DECISION THEORY. Given two boxes, B1 which contains $1000 and B2 which contains either nothing or a million dollars, you may pick either B2 or both. However, at some time before the choice is made, an omniscient Being has predicted what your decision will be and filled B2 with a million dollars if he expects you to take it, or with nothing if he expects you to take both.

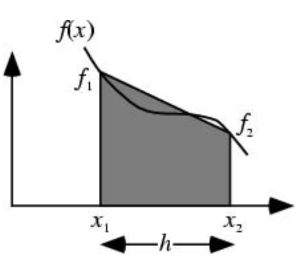
Newton Number

KISSING NUMBER

Newton-Bessel Formula

BESSEL'S FINITE DIFFERENCE FORMULA



Newton-Cotes Formulas

The Newton-Cotes formulas are an extremely useful and straightforward family of NUMERICAL INTEGRATION techniques.

To integrate a function $f(x)$ over some interval $[a, b]$, divide it into n equal parts such that $f_n = f(x_n)$ and $h \equiv (b-a)/n$. Then find POLYNOMIALS which approximate the tabulated function, and integrate them to approximate the AREA under the curve. To find the fitting POLYNOMIALS, use LAGRANGE INTERPOLATING POLYNOMIALS. The resulting formulas are called Newton-Cotes formulas, or QUADRATURE FORMULAS.

Newton-Cotes formulas may be "closed" if the interval $[x_1, x_n]$ is included in the fit, "open" if the points $[x_2, x_{n-1}]$ are used, or a variation of these two. If the formula uses n points (closed or open), the COEFFICIENTS of terms sum to $n-1$.

If the function $f(x)$ is given explicitly instead of simply being tabulated at the values x_i, the best numerical method of integration is called GAUSSIAN QUADRATURE. By picking the intervals at which to sample the function, this procedure produces more accurate approximations (but is significantly more complicated to implement).

The 2-point closed Newton-Cotes formula is called the TRAPEZOIDAL RULE because it approximates the area under a curve by a TRAPEZOID with horizontal base and sloped top (connecting the endpoints x_1 and x_2). If the first point is x_1, then the other endpoint will be located at

$$x_2 = x_1 + h, \tag{1}$$

and the LAGRANGE INTERPOLATING POLYNOMIAL through the points (x_1, f_1) and (x_2, f_2) is

$$P_2(x) = \frac{x - x_2}{x_1 - x_2} f_1 + \frac{x - x_1}{x_2 - x_1} f_2$$

$$= \frac{x - x_1 - h}{-h} f_1 + \frac{x - x_1}{h} f_2$$

$$\frac{x}{h}(f_2 - f_1) + \left(f_1 + \frac{x_1}{h} f_1 - \frac{x_1}{h} f_2\right). \tag{2}$$

Integrating over the interval (i.e., finding the area of the trapezoid) then gives

$$\int_{x_1}^{x_2} f(x)\,dx = \int_{x_1}^{x_1+h} P_2(x)\,dx$$

$$= \frac{1}{2h}(f_2 - f_1)\left[x^2\right]_{x_1}^{x_2} + \left(f_1 + \frac{x_1}{h} f_1 - \frac{x_1}{h} f_2\right)[x]_{x_1}^{x_2}$$

$$= \frac{1}{2h}(f_2 - f_1)(x_2 + x_1)(x_2 - x_1) + (x_2 - x_1)$$

$$\times \left(f_1 + \frac{x_1}{h} f_1 - \frac{x_1}{h} f_2\right)$$

$$= \tfrac{1}{2}(f_2 - f_1)(2x_1 + h) + f_1 h + x_1(f_1 - f_2)$$

$$= x_1(f_2 - f_1) + \tfrac{1}{2}h(f_2 - f_1) + hf_1 - x_1(f_2 - f_1)$$

$$= \tfrac{1}{2}h(f_1 + f_2) - \tfrac{1}{12}h^3 f''(\xi). \tag{3}$$

This is the trapezoidal rule (Ueberhuber 1997, p. 100), with the final term giving the amount of error (which, since $x_1 \le \xi \le x_2$, is no worse than the maximum value of $f''(\xi)$ in this range).

The 3-point rule is known as SIMPSON'S RULE. The ABSCISSAS are

$$x_2 = x_1 + h \tag{4}$$

$$x_3 = x_1 + 2h \tag{5}$$

and the LAGRANGE INTERPOLATING POLYNOMIAL is

$$P_3(x) = \frac{(x - x_2)(x - x_3)}{(x_1 - x_2)(x_1 - x_3)} f_1 + \frac{(x - x_1)(x - x_3)}{(x_2 - x_1)(x_2 - x_3)} f_2$$

$$+ \frac{(x - x_1)(x - x_2)}{(x_3 - x_1)(x_3 - x_2)} f_3$$

$$= \frac{x^2 - x(x_2 + x_3) + x_2 x_3}{h(2h)} f_1$$

$$+ \frac{x^2 - x(x_1 + x_3) + x_1 x_3}{h(-h)} f_2$$

$$+\frac{x^2 - x(x_1 + x_2) + x_1x_2}{2h(h)} f_3$$

$$= \frac{1}{h^2} \{x^2 \left(\tfrac{1}{2}f_1 - f_2 - \tfrac{1}{2}f_3\right) + x\left[-\tfrac{1}{2}(2x_1 + 3h)f_1\right.$$

$$+(2x_1 + 2h)f_2 - \tfrac{1}{2}(2x_1 + h)] + \left[\tfrac{1}{2}(x_1 + h)(x_1 + 2h)f_1\right.$$

$$-x_1(x_1 + 2h)f_2 + \tfrac{1}{2}x_1(x_1 + h)f_3]\}. \quad (6)$$

Integrating and simplifying gives

$$\int_{x_1}^{x_2} f(x)dx = \int_{x_1}^{x_1+2h} P_3(x)dx$$
$$= \tfrac{1}{3}h(f_1 + 4f_2 + f_3) - \tfrac{1}{90}h^5 f^{(4)}(\xi) \quad (7)$$

(Ueberhuber 1997, p. 100).

The 4-point closed rule is SIMPSON'S 3/8 RULE,

$$\int_{x_1}^{x_4} f(x)dx = \tfrac{3}{8}h(f_1 + 3f_2 + 3f_3 + f_4) - \tfrac{3}{80}h^5 f^{(4)}(\xi) \quad (8)$$

(Ueberhuber 1997, p. 100). The 5-point closed rule is BODE'S RULE,

$$\int_{x_1}^{x_5} f(x)dx = \tfrac{2}{45}h(7f_1 + 32f_2 + 12f_3 + 32f_4 + 7f_5)$$
$$- \tfrac{8}{945}h^7 f^{(6)}(\xi) \quad (9)$$

(Abramowitz and Stegun 1972, p. 886). Higher order rules include the 6-point

$$\int_{x_1}^{x_6} f(x)dx = \tfrac{5}{288}h(19f_1 + 75f_2 + 50f_3 + 50f_4 + 75f_5$$
$$+19f_6) - \tfrac{275}{12096}h^7 f^{(6)}(\xi), \quad (10)$$

7-point

$$\int_{x_1}^{x_7} f(x)dx = \tfrac{1}{140}h(41f_1 + 216f_2 + 27f_3 + 272f_4$$
$$+27f_5 + 216f_6 + 41f_7) - \tfrac{9}{1400}h^9 f^{(8)}(\xi), \quad (11)$$

8-point

$$\int_{x_1}^{x_8} f(x)dx = \tfrac{7}{17280}h(751f_1 + 3577f_2 + 1323f_2 + 2989f_3$$
$$+2989f_5 + 1323f_6 + 3577f_7 + 751f_8)$$
$$- \tfrac{8183}{518400}h^9 f^{(8)}(\xi), \quad (12)$$

9-point

$$\int_{x_1}^{x_9} f(x)dx = \tfrac{4}{14175}h(989f_1 + 5888f_2 - 928f_3$$
$$+10496f_4 + 4540f_5 + 10496f_6 - 928f_7 + 5888f_8 + 989f_9)$$
$$-\tfrac{2368}{467775}h^{11} f^{(10)}(\xi) \quad (13)$$

(Ueberhuber 1997, p. 100), 10-point

$$\int_{x_1}^{x_{10}} f(x)dx = \tfrac{9}{89600}h[2857(f_1 + f_{10})$$
$$+15741(f_2 + f_9) + 1080(f_3 + f_8) + 19344(f_4 + f_7)$$
$$+5788(f_5 + f_6)] - \tfrac{173}{14620}h^{11} f^{(10)}(\xi), \quad (14)$$

and 11-point

$$\int_{x_1}^{x_{11}} f(x)dx = \tfrac{5}{299376}h[16067(f_1 + f_{11})$$
$$+106300(f_2 + f_{10})] - 48525(f_3 + f_9) + 272400(f_4 + f_8)$$
$$-260550(f_5 + f_7) + 427368f_6] - \tfrac{1346350}{326918592}h^{13} f^{(12)}(\xi) \quad (15)$$

rules.

In general, the n-point rule is given by the analytic expression

$$\int_{x_1}^{x_n} f(x)dx = h\sum_{i=1}^{n} H_{n,i} f_i, \quad (16)$$

where

$$H_{n,r+1} = \frac{(-1)^{n-r}}{r!(n-r)!}\int_0^n t(t-1)\cdots(t-r+1)$$
$$\times (t-r-1)\cdots(t-n)dt \quad (17)$$

(Whittaker and Robinson 1967, p. 154).

Closed "extended" rules use multiple copies of lower order closed rules to build up higher order rules. By appropriately tailoring this process, rules with particularly nice properties can be constructed. For n tabulated points, using the TRAPEZOIDAL RULE $(n-1)$ times and adding the results gives

$$\int_{x_1}^{x_n} f(x)dx = \left(\int_{x_1}^{x_2} + \int_{x_2}^{x_3} + \cdots \int_{x_{n-1}}^{x_n}\right) f(x)\, dx$$
$$= \tfrac{1}{2}h[(f_1 + f_2) + (f_2 + f_3) + \cdots + (f_{n-2} + f_{n-1})$$
$$+(f_{n-1} + f_n)]$$
$$= h\left(\tfrac{1}{2}f_1 + f_2 + f_3 + \cdots + f_{n-2} + f_{n-1} + \tfrac{1}{2}f_n\right)$$
$$-\tfrac{1}{12}nh^3 f''(\xi) \quad (18)$$

(Ueberhuber 1997, p. 107). Using a series of refinements on the extended TRAPEZOIDAL RULE gives the method known as ROMBERG INTEGRATION. A 3-point extended rule for ODD n is

$$\int_{x_1}^{x_n} f(x)\,dx = h\left[\left(\tfrac{1}{3}f_1+\tfrac{4}{3}f_2+\tfrac{1}{3}f_3\right)+\left(\tfrac{1}{3}f_3+\tfrac{4}{3}f_4+\tfrac{1}{3}f_5\right)\right.$$

$$\left.+\cdots+\left(\tfrac{1}{3}f_{n-4}+\tfrac{4}{3}f_{n-3}+\tfrac{1}{3}f_{n-2}\right)+\left(\tfrac{1}{3}f_{n-2}+\tfrac{4}{3}f_{n-1}+\tfrac{1}{3}f_n\right)\right]$$

$$=\tfrac{1}{3}h(f_1+4f_2+2f_3+4f_4+2f_5+\ldots+4f_{n-1}+f_n)$$

$$-\tfrac{n-1}{2}\tfrac{1}{90}h^5 f^{(4)}(\xi). \tag{19}$$

Applying SIMPSON'S 3/8 RULE, then SIMPSON'S RULE (3-point) twice, and adding gives

$$\left[\int_{x_1}^{x_4}+\int_{x_4}^{x_6}+\int_{x_1}^{x_4}\right] f(x)\,dx$$

$$=h\left[\left(\tfrac{3}{8}f_1+\tfrac{9}{8}f_2+\tfrac{9}{8}f_3+\tfrac{3}{8}f_4\right)+\left(\tfrac{1}{3}f_4+\tfrac{4}{3}f_5+\tfrac{1}{3}f_6\right)\right.$$

$$\left.+\left(\tfrac{1}{3}f_6+\tfrac{4}{3}f_7+\tfrac{1}{3}f_8\right)\right]$$

$$=h\left[\tfrac{3}{8}f_1+\tfrac{9}{8}f_2+\tfrac{9}{8}f_3+\left(\tfrac{3}{8}+\tfrac{1}{3}\right)f_4+\tfrac{4}{3}f_5\right.$$

$$\left.+\left(\tfrac{1}{3}+\tfrac{1}{3}\right)f_6+\tfrac{4}{3}f_7+\tfrac{1}{3}f_8\right]$$

$$=h\left(\tfrac{3}{8}f_1+\tfrac{9}{8}f_2+\tfrac{9}{8}f_3+\tfrac{17}{24}f_4+\tfrac{4}{3}f_5+\tfrac{2}{3}f_6+\tfrac{4}{3}f_7+\tfrac{1}{3}f_8\right). \tag{20}$$

Taking the next Simpson's 3/8 step then gives

$$\int_{x_8}^{x_{11}} f(x)\,dx = h\left(\tfrac{3}{8}f_8+\tfrac{9}{8}f_9+\tfrac{9}{8}f_{10}+\tfrac{3}{8}f_{11}\right). \tag{21}$$

Combining with the previous result gives

$$\int_{x_1}^{x_{11}} f(x)\,dx = h\left[\tfrac{3}{8}f_1+\tfrac{9}{8}f_2+\tfrac{9}{8}f_3+\tfrac{17}{24}f_4+\tfrac{4}{3}f_5\right.$$

$$\left.+\tfrac{2}{3}f_6+\tfrac{4}{3}f_7+\left(\tfrac{1}{3}+\tfrac{3}{8}\right)f_8+\tfrac{9}{8}f_9+\tfrac{9}{8}f_{10}+\tfrac{3}{8}f_{11}\right]$$

$$=h\left(\tfrac{3}{8}f_1+\tfrac{9}{8}f_2+\tfrac{9}{8}f_3+\tfrac{17}{24}f_4+\tfrac{4}{3}f_5+\tfrac{2}{3}f_6+\tfrac{4}{3}f_7\right.$$

$$\left.+\tfrac{17}{24}f_8+\tfrac{9}{8}f_9+\tfrac{9}{8}f_{10}+\tfrac{3}{8}f_{11}\right), \tag{22}$$

where terms up to f_{10} have now been completely determined. Continuing gives

$$h\left(\tfrac{3}{8}f_1+\tfrac{9}{8}f_2+\tfrac{9}{8}f_3+\tfrac{17}{24}f_4+\tfrac{4}{3}f_5+\tfrac{2}{3}f_6+\ldots\right.$$

$$\left.+\tfrac{2}{3}f_{n-5}+\tfrac{4}{3}f_{n-4}+\tfrac{17}{24}f_{n-3}+\tfrac{9}{8}f_{n-2}+\tfrac{9}{8}f_{n-1}+\tfrac{3}{8}f_n\right). \tag{23}$$

Now average with the 3-point result

$$h\left(\tfrac{1}{3}f_1+\tfrac{4}{3}f_2+\tfrac{2}{3}f_3+\tfrac{4}{3}f_4+\tfrac{2}{3}f_5+\tfrac{4}{3}f_{n-1}+\tfrac{1}{3}f_n\right) \tag{24}$$

to obtain

$$h\left[\tfrac{17}{48}f_1+\tfrac{59}{48}f_2+\tfrac{43}{48}f_4+\tfrac{49}{48}f_4+(f_5+f_6+\ldots+f_{n-5}+f_{n-4})\right.$$

$$\left.+\tfrac{49}{48}f_{n-3}+\tfrac{43}{38}f_{n-2}+\tfrac{59}{48}f_{n-1}+\tfrac{17}{48}f_n\right]+\mathcal{O}(n^{-4}). \tag{25}$$

Note that all the middle terms now have unity COEFFICIENTS. Similarly, combining a 4-point with the (2+4)-point rule gives

$$h\left(\tfrac{5}{12}f_1+\tfrac{13}{12}f_2+f_3+f_4+\ldots+f_{n-3}+f_{n-2}+\tfrac{13}{12}f_{n-1}+\tfrac{5}{12}\right)$$

$$+\mathcal{O}(n^{-3}). \tag{26}$$

Other Newton-Cotes rules occasionally encountered include DURAND'S RULE

$$\int_{x_1}^{x_n} f(x)\,dx = h\left(\tfrac{2}{5}f_1+\tfrac{11}{10}f_2+f_3+\ldots+f_{n-2}+\tfrac{11}{10}f_{n-1}+\tfrac{2}{5}f_n\right) \tag{27}$$

(Beyer 1987), HARDY'S RULE

$$\int_{x_0-3h}^{x_0+3h} f(x)\,dx$$

$$=\tfrac{1}{100}h(28f_{-3}+162f_{-2}+22f_0+162f_2+28f_3)$$

$$+\tfrac{9}{1400}h^7\left[2f^{(4)}(\xi_2)-h^2 f^{(8)}(\xi_1)\right], \tag{28}$$

and WEDDLE'S RULE

$$\int_{x_1}^{x_{6n}} f(x)\,dx = \tfrac{3}{10}h(f_1+5f_2+f_3+6f_4+5f_5+f_6$$

$$+\ldots+5f_{6n-1}+f_{6n}) \tag{29}$$

(Beyer 1987).

The open Newton-Cotes rules use points outside the integration interval, yielding the 1-point

$$\int_{x_0}^{x_2} f(x)\,dx = 2hf_1, \tag{30}$$

2-point

$$\int_{x_0}^{x_3} f(x)\,dx = \int_{x_1-h}^{x_1+2h} P_2(x)\,dx$$

$$=\tfrac{1}{2h}(f_2-f_1)\left[x^2\right]_{x_1-h}^{x_1+2h}+\left(f_1+\frac{x_1}{h}f_1-\frac{x_1}{h}f_2\right)[x]_{x_1-h}^{x_1+2h}$$

$$=\tfrac{3}{2}h(f_1+f_2)+\tfrac{1}{4}h^3 f''(\xi), \tag{31}$$

3-point

$$\int_{x_0}^{x_4} f(x)\,dx = \tfrac{4}{3}h(2f_1-f_2+2f_3)+\tfrac{28}{90}h^5 f^{(4)}(\xi), \tag{32}$$

4-point

$$\int_{x_0}^{x_5} f(x)\,dx = \tfrac{5}{24}h(11f_1+f_2+f_3+11f_4)$$

$$+\tfrac{95}{144}h^5 f^{(4)}(\xi), \tag{33}$$

5-point

$$\int_{x_0}^{x_6} f(x)\,dx = \tfrac{6}{20}h(11f_1 - 14f_2 + 26f_3 - 14f_4 + 11f_5) - \tfrac{41}{140}h^7 f^{(6)}(\xi), \tag{34}$$

6-point

$$\int_{x_0}^{x_7} f(x)dx = \tfrac{7}{1440}h(611f_1 - 453f_2 + 562f_3 + 562f_4 - 453f_5 + 611f_6) - \tfrac{5257}{8640}h^7 f^{(6)}(\xi), \tag{35}$$

and 7-point

$$\int_{x_0}^{x_8} f(x)dx = \tfrac{8}{945}h(460f_1 - 954f_2 + 2196f_3 - 2459f_4 + 2196f_5 - 954f_6 + 460f_7) - \tfrac{3956}{14175}h^9 f^{(8)}(\xi) \tag{36}$$

rules.

A 2-point open extended formula is

$$\int_{x_1}^{x_n} f(x)dx = h\left[\left(\tfrac{1}{2}f_1 + f_2 + \ldots + f_{n-1} + \tfrac{1}{2}f_n\right) + \tfrac{1}{24}(-f_0 + f_2 + f_{n-1} - f_{n+1})\right] + \tfrac{11(n+1)}{720}h^5 f^{(4)}(\xi). \tag{37}$$

Single interval extrapolative rules estimate the integral in an interval based on the points around it. An example of such a rule is

$$hf_1 + \mathcal{O}(h^2 f') \tag{38}$$

$$\tfrac{1}{2}h(3f_1 - f_2) + \mathcal{O}(h^3 f'') \tag{39}$$

$$\tfrac{1}{12}h(23f_1 - 16f_2 + 5f_3) + \mathcal{O}(h^4 f^{(3)}) \tag{40}$$

$$\tfrac{1}{24}h(55f_1 - 59f_2 + 37f_3 - 9f_4) + \mathcal{O}(h^5 f^{(4)}). \tag{41}$$

Newton's Diverging Parabolas

Curves with CARTESIAN equation

$$ay^2 = x(x^2 - 2bx + c)$$

with $a > 0$. The above equation represents the third class of Newton's classification of CUBIC CURVES, which Newton divided into five species depending on the ROOTS of the cubic in x on the right-hand side of the equation. Newton described these cases as having the following characteristics:

1. "All the ROOTS are REAL and unequal. Then the Figure is a diverging Parabola OF THE FORM of a Bell, with an Oval at its Vertex.
2. Two of the ROOTS are equal. A PARABOLA will be formed, either Nodated by touching an Oval, or Punctate, by having the Oval infinitely small.
3. The three ROOTS are equal. This is the NEILIAN PARABOLA, commonly called SEMI-CUBICAL.
4. Only one REAL ROOT. If two of the ROOTS are impossible, there will be a Pure PARABOLA of a Bell-like Form"

(MacTutor Archive).

Newton's Divided Difference Interpolation Formula

Let

$$\pi_n(x) \equiv \prod_{i=1}^{n}(x - x_n), \tag{1}$$

then

$$f(x) = f_0 + \sum_{k=1}^{n} x_{k-1}(x)[x_0, x_1 \ldots, x_k] + R_n, \tag{2}$$

where $[x_1, \ldots]$ is a DIVIDED DIFFERENCE, and the remainder is

$$R_n(x) = \pi_n(x)[x_0, \ldots, x_n, x] = \pi_n(x)\frac{f^{(n+1)}(\xi)}{(n+1)} \tag{3}$$

for $x_0 < \xi < x_n$.

Newton's Formulas

Let a TRIANGLE have side lengths a, b, and c with opposite angles A, B, and C. Then

$$\frac{b+c}{a} = \frac{\cos\left[\frac{1}{2}(B-C)\right]}{\sin\left(\frac{1}{2}A\right)}$$

$$\frac{c+a}{b} = \frac{\cos\left[\frac{1}{2}(C-A)\right]}{\sin\left(\frac{1}{2}B\right)}$$

$$\frac{a+b}{c} = \frac{\cos\left[\frac{1}{2}(A-B)\right]}{\sin\left(\frac{1}{2}C\right)}.$$

Newton's Forward Difference Formula

A FINITE DIFFERENCE identity giving an interpolated value between tabulated points $\{f_p\}$ in terms of the first value f_0 and the POWERS of the FORWARD DIFFERENCE Δ. For $a \in [0, 1]$, the formula states

$$f_a = f_0 + a\Delta + \tfrac{1}{2!}a(a-1)\Delta^2 + \tfrac{1}{3!}a(a-1)(a-2)\Delta^3 + \ldots$$

When written in the form

$$f(x+a) = \sum_{n=0}^{\infty}\frac{(a)_n \Delta^n f(x)}{n!}$$

with $(a)_n$ the POCHHAMMER SYMBOL, the formula looks suspiciously like a finite analog of a TAYLOR SERIES expansion. This correspondence was one of the motivating forces for the development of UMBRAL CALCULUS.

The DERIVATIVE of Newton's forward difference formula gives MARKOFF'S FORMULAS.

Newton's Identities

NEWTON'S RELATIONS

Newton's Iteration

An algorithm for computing the SQUARE ROOT of a number n quadratically as $\lim_{k\to\infty} x_k$,

$$x_{k+1} = \frac{1}{2}\left(x_k + \frac{n}{x_k}\right),$$

where $x_0 = 1$. The first few approximants to $\sqrt{n}$ are given by

$$1, \tfrac{1}{2}(1+n), \frac{1+6n+n^2}{4(n+1)},$$
$$\frac{1+28n+70n^2+28n^3+n^4}{8(1+n)(1+6n+n^2)}, \ldots$$

For $\sqrt{2}$, this gives the convergents as 1, 3/2, 17/12, 577/408, 665857/470832, ... (Sloane's A051008 and A051009).

Newton's Method

A ROOT-finding ALGORITHM which uses the first few terms of the TAYLOR SERIES of a function $f(x)$ in the vicinity of a suspected ROOT to zero in on the root. It is also called the Newton-Raphson method. For $f(x)$ a POLYNOMIAL, Newton's method is essentially the same as HORNER'S METHOD. The TAYLOR SERIES of $f(x)$ about the point $x+\varepsilon$ is given by

$$f(x+\varepsilon) = f(x) + f'(x)\varepsilon + \tfrac{1}{2}f''(x)\varepsilon^2 + \ldots. \qquad (1)$$

Keeping terms only to first order,

$$f(x+\varepsilon) \approx f(x) + f'(x)\varepsilon. \qquad (2)$$

This expression can be used to estimate the amount of offset ε needed to land closer to the root starting from an initial guess x_0. Setting $f(x_0+\varepsilon) = 0$ and solving (2) for ε gives

$$\varepsilon_0 = -\frac{f(x_0)}{f'(x_0)}, \qquad (3)$$

which is the first-order adjustment to the ROOT's position. By letting $x_1 = x_0 + \varepsilon_0$, calculating a new ε_1, and so on, the process can be repeated until it converges to a root.

Unfortunately, this procedure can be unstable near a horizontal ASYMPTOTE or a LOCAL MINIMUM. However, with a good initial choice of the ROOT's position, the algorithm can by applied iteratively to obtain

$$x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)} \qquad (4)$$

for $n = 1, 2, 3, \ldots$. An initial point x_0 that provides safe convergence of Newton's method is called an APPROXIMATE ZERO.

The error ε_{n+1} after the $(n+1)$st iteration is given by

$$\begin{aligned}\varepsilon_{n+1} &= \varepsilon_n + (x_{n+1} - x_n)\\ &= \varepsilon_n - \frac{f(x_n)}{f'(x_n)}. \qquad (5)\end{aligned}$$

But

$$\begin{aligned}f(x_n) &= f(x) + f'(x)\varepsilon_n + \tfrac{1}{2}f''(x)\varepsilon_n^2 + \ldots\\ &= f'(x)\varepsilon_n + \tfrac{1}{2}f''(x)\varepsilon_n^2 + \ldots \qquad (6)\end{aligned}$$

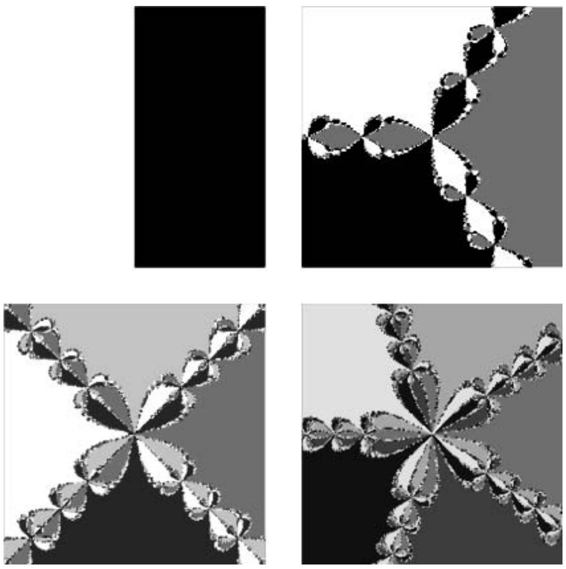
$$f'(x_n) = f'(x) + f''(x)\varepsilon_n + \ldots, \qquad (7)$$

so

$$\begin{aligned}\frac{f(x_n)}{f'(x_x)} &= \frac{f'(x)\varepsilon_n + \tfrac{1}{2}f''(x)\varepsilon_n^2 + \ldots}{f'(x)f''(x)\varepsilon_n + \ldots}\\ &\approx \frac{f'(x)\varepsilon + \tfrac{1}{2}f''(x)\varepsilon_n^2}{f'(x) + f''(x)\varepsilon_n} = \varepsilon_n + \frac{f''(x)}{2f'(x)}\varepsilon_n^2, \qquad (8)\end{aligned}$$

and (5) becomes

$$\varepsilon_{n+1} = \varepsilon_n - \left[\varepsilon_n + \frac{f''(x)}{2f'(x)}\varepsilon_n^2\right] = -\frac{f''(x)}{2f'(x)}\varepsilon_n^2. \qquad (9)$$



Therefore, when the method converges, it does so quadratically.

A FRACTAL is obtained by applying Newton's method to finding a ROOT of $z^n - 1 = 0$ (Mandelbrot 1983, Gleick 1988, Peitgen and Saupe 1988, Press *et al.* 1992, Dickau 1997). Iterating for a starting point z_0

gives

$$z_{i+1} = z_i - \frac{z_i^n - 1}{n z_i^{n-1}}. \tag{10}$$

Since this is an nth order POLYNOMIAL, there are n ROOTS to which the algorithm can converge.

Coloring the BASIN OF ATTRACTION (the set of initial points z_0 which converge to the same ROOT) for each ROOT a different color then gives the above plots, corresponding to $n = 2$, 3, 4, and 5.

Newton's Parallelogram

Approximates the possible values of y in terms of x if

$$\sum_{i,j=0}^{n} a_{ij} x^i y^j = 0.$$

Newton's Relations

Let s_i be the sum of the products of distinct ROOTS r_j of the POLYNOMIAL equation of degree n

$$a_n x^n + a_{n-1} x^{n-1} + \ldots + a_1 x + a_0 = 0, \tag{1}$$

where the roots are taken i at a time (i.e., s_i is defined as the SYMMETRIC POLYNOMIAL $\prod_i (r_1, \ldots, r_n)$) s_i is defined for $i = 1, \ldots, n$. For example, the first few values of s_i are

$$s_1 = r_1 + r_2 + r_3 + r_4 + \ldots \tag{2}$$

$$s_2 = r_1 r_2 + r_1 r_3 + r_1 r_4 + r_2 r_3 + \ldots \tag{3}$$

$$s_3 = r_1 r_2 r_3 + r_1 r_2 r_4 + r_2 r_3 r_4 + \ldots, \tag{4}$$

and so on. Then

$$s_i = (-1)^i \frac{a_{n-i}}{a_n}. \tag{5}$$

This can be seen for a second DEGREE POLYNOMIAL by multiplying out,

$$\begin{aligned} a_2 x^2 + a_1 x + a_0 &= a_2 (x - r_1)(x - r_2) \\ &= a_2 \left[x^2 - (r_1 + r_2) x + r_1 r_2\right], \end{aligned} \tag{6}$$

so

$$s_1 = \sum_{i=1}^{2} r_i = r_1 + r_2 = -\frac{a_1}{a_2} \quad (7)$$

$$s_2 = \sum_{\substack{i,j=1\\ i \neq j}}^{2} r_i r_j = r_1 r_2 = \frac{a_0}{a_2}, \quad (8)$$

and for a third DEGREE POLYNOMIAL,

$$a_3x^3 + a_2x^2 + a_1x + a_0 = a_3(x-r_1)(x-r_2)(x-r_3)$$
$$= a_3\left[x^3 - (r_1+r_2+r_3)x^2 + (r_1r_2+r_1r_3+r_2r_3)x - r_1r_2r_3\right], \quad (9)$$

so

$$s_1 = \sum_{i=1}^{3} r_i = -\frac{a_2}{a_3} \quad (10)$$

$$s_2 = \sum_{\substack{i,j\\ i \neq j}}^{3} r_i r_j = r_1r_2 + r_1r_3 + r_2r_3 = \frac{a_1}{a_3} \quad (11)$$

$$s_3 = \sum_{\substack{i,j,k\\ i \neq j \neq k}}^{3} r_i r_j r_k = r_1r_2r_3 = -\frac{a_0}{a_3}. \quad (12)$$

Newton-Stirling Formula

STIRLING'S FINITE DIFFERENCE FORMULA

Next Prime

The next prime function $NP(n)$ gives the smallest PRIME larger than n. The function can be given explicitly as

$$NP(n) = p_{1+\pi(n)},$$

where p_i is the ith PRIME and $\pi(n)$ is the PRIME COUNTING FUNCTION. For $n = 1, 2, \ldots$ the values are 2, 3, 5, 5, 7, 7, 11, 11, 11, 11, 13, 13, 17, 17, 17, 17, 19, ... (Sloane's A007918).

Nexus Number

A FIGURATE NUMBER built up of the nexus of cells less than n steps away from a given cell. In k-D, the $(n+1)$th nexus number is given by

$$N_{n+1}(k) = \sum_{i=0}^{k} \binom{k}{i} n^i,$$

where $\binom{n}{n}$ is a BINOMIAL COEFFICIENT. The first few k-dimensional nexus numbers are given in the table below.

k	N_{n+1}	name
0	1	unit
1	$1+2n$	ODD NUMBER
2	$1+3n+3n^2$	HEX NUMBER
3	$1+4n+6n^2+4n^3$	RHOMBIC DODECAHEDRAL NUMBER

See also BINOMIAL SUMS, HEX NUMBER, ODD NUMBER, RHOMBIC DODECAHEDRAL NUMBER

Neyman-Pearson Lemma

If there exists a critical region C of size α and a NONNEGATIVE constant k such that

$$\frac{\prod_{i=1}^{n} f(x_i|\theta_1)}{\prod_{i=1}^{n} f(x_i|\theta_0)} \geq k$$

for points in C and

$$\frac{\prod_{i=1}^{n} f(x_i|\theta_1)}{\prod_{i=1}^{n} f(x_i|\theta_0)} \leq k$$

for points not in C, then C is a best critical region of size α.

Nicomachus's Theorem

The nth CUBIC NUMBER n^3 is a sum of n consecutive ODD NUMBERS, for example

$$\begin{aligned} 1^3 &= 1 \\ 2^3 &= 3+5 \\ 3^3 &= 7+9+11 \\ 4^3 &= 13+15+17+19, \end{aligned}$$

etc. This identity follows from

$$\sum_{i=1}^{n}[n(n-1)-1+2i] = n^3.$$

It also follows from this fact that

$$\sum_{k=1}^{n} k^3 = \left(\sum_{k=1}^{n} k\right)^2.$$

Nicomedes' Conchoid

CONCHOID OF NICOMEDES

Nielsen Generalized Polylogarithm

A generalization of the POLYLOGARITHM function defined by

$$S_{n,p}(z) = \frac{(-1)^{n+p-1}}{(n-1)!p!}\int_0^1 \frac{(\ln t)^{n-1}[\ln(1-zt)]^p}{t}dt.$$

The function reduces to the usual POLYLOGARITHM for the case

$$S_{n-1,1}(z) = \mathrm{Li}_n(z).$$

The function is implemented in *Mathematica* 4.0 as `PolyLog[n, p, z]`.

See also POLYLOGARITHM

Nielsen-Ramanujan Constants

N.B. A detailed online essay by S. Finch was the starting point for this entry.

N. Nielsen (1909) and Ramanujan (Berndt 1985) considered the integrals

$$a_k = \int_1^2 \frac{(\ln x)^k}{x-1}dx. \quad (1)$$

They found the values for $k=1$ and 2. The general constants for $k>3$ were found by Levin (1950) and, much later, independently by V. Adamchik (Finch),

$$a_p = p!\zeta(p+1) - \frac{p(\ln 2)^{p+1}}{p+1} - p!\sum_{k=0}^{p-1} \times \frac{\mathrm{Li}_{p+1-k}\left(\frac{1}{2}\right)(\ln 2)^k}{k!}, \quad (2)$$

where $\zeta(z)$ is the RIEMANN ZETA FUNCTION and $\mathrm{Li}_n(x)$ is the POLYLOGARITHM. The first few values are

$$a_1 = \tfrac{1}{2}\zeta(2) = \tfrac{1}{12}\pi^2 \quad (3)$$

$$a_2 = \tfrac{1}{4}\zeta(3) \quad (4)$$

$$a_3 = \tfrac{1}{15}\pi^4 + \tfrac{1}{4}\pi^2(\ln 2)^2 - \tfrac{1}{4}(\ln 2)^4 - 6\,\mathrm{Li}_4\left(\tfrac{1}{2}\right) - \tfrac{21}{4}(\ln 2)\zeta(3) \quad (5)$$

$$a_4 = \tfrac{2}{3}\pi^2(\ln 2)^3 - \tfrac{4}{5}(\ln 2)^5 - 24(\ln 2)\mathrm{Li}_4\left(\tfrac{1}{2}\right) - 24\,\mathrm{Li}_5\left(\tfrac{1}{2}\right) - \tfrac{21}{2}(\ln 2)^2\zeta(3) + 24\zeta(5). \quad (6)$$

Nilalgebra

NILPOTENT ALGEBRA

Nilmanifold

Let N be a NILPOTENT, connected, SIMPLY CONNECTED LIE GROUP, and let D be a discrete SUBGROUP of N with compact right QUOTIENT SPACE. Then N/D is called a nilmanifold.

Nilpotent Algebra

An algebra, also called a nilalgebra, consisting only of NILPOTENT ELEMENTS.

See also NILPOTENT ELEMENT

References

Schafer, R. D. "Nilpotent Algebras." §3.1 in *An Introduction to Nonassociative Algebras.* New York: Dover, pp. 27–32, 1996.

Nilpotent Element

An element B of a RING is nilpotent if there exists a POSITIVE INTEGER k for which $B^k = 0$.

See also ENGEL'S THEOREM

Nilpotent Group

A GROUP G for which the chain of groups

$$I = \mathbb{Z}_0 \subseteq \mathbb{Z}_1 \subseteq \ldots \subseteq \mathbb{Z}_n$$

with $\mathbb{Z}_{k+1}/\mathbb{Z}_k$ (equal to the CENTER of $G/\mathbb{Z}_k$) terminates finitely with 0 is called a nilpotent group. Here, $\mathbb{Z}_n$ denotes a CYCLIC GROUP of order n.

See also CENTER (GROUP), NILPOTENT LIE GROUP

Nilpotent Lie Algebra

A LIE ALGEBRA is nilpotent when its LOWER CENTRAL SERIES $\mathfrak{g}_k$ vanishes for some k. Any nilpotent Lie algebra is also SOLVABLE. The basic example of a nilpotent Lie algebra is the VECTOR SPACE of strictly

UPPER TRIANGULAR MATRICES, such as the Lie algebra of the HEISENBERG GROUP.

The following *Mathematica* function tests whether a Lie algebra $\mathfrak{g}$ is nilpotent, given a list of matrices which is a basis for $\mathfrak{g}$.

```
MatrixBasis[a_-
List]:=Partition[#1,Length[a[[1]]]]&/@
   LatticeReduce[Flatten/@a]
                    LieCommutator[a_,b_]:=a.b-b.a
NextLCS[gold_List, {}]={};
            NextLCS[gold_List,        g_List]:=
MatrixBasis[Flatten[Outer[LieCommutator,gold,-
g,1],1]]              NilpotentLieQ[g_List]:=
FixedPoint[NextLCS[g,#1]&,g]=={}
```

For example,

```
borel5=Flatten[Table[ReplacePart[
                                              Ta-
ble[0,{i,5},{j,5}],1,{k,l}],{k,5},{l,k,5}],1];
  NilpotentLieQ[borel5]
```

yields `False`, while

```
uni5=Flatten[Table[ReplacePart[
                                              Ta-
ble[0,{i,5},{j,5}],1,{k,l}],{k,5},{l,k-
+1,5}],1];
  NilpotentLieQ[uni5]
```

yields `True`.

See also COMMUTATOR SERIES (LIE ALGEBRA), LIE ALGEBRA, LIE GROUP, LOWER CENTRAL SERIES (LIE ALGEBRA), NILPOTENT LIE GROUP, REPRESENTATION (LIE ALGEBRA), REPRESENTATION (NILPOTENT LIE GROUP), SOLVABLE LIE GROUP, UNIPOTENT

Nilpotent Lie Group

A nilpotent Lie group is a LIE GROUP G which is CONNECTED and whose LIE ALGEBRA is a NILPOTENT LIE ALGEBRA $\mathfrak{g}$. That is, its LOWER CENTRAL SERIES

$$\mathfrak{g}_1[\mathfrak{g},\mathfrak{g}],\mathfrak{g}_2=[\mathfrak{g},\mathfrak{g}_1],\ldots \tag{1}$$

eventually vanishes, $\mathfrak{g}_k=0$ for some k. So a nilpotent Lie group is a special case of a SOLVABLE LIE GROUP.

The basic example is the GROUP of UPPER TRIANGULAR MATRICES with 1s on their diagonals, e.g.,

$$\begin{bmatrix} 1 & a_{12} & a_{13} \\ 0 & 1 & a_{23} \\ 0 & 0 & 1 \end{bmatrix}, \tag{2}$$

which is called the HEISENBERG GROUP. Its LOWER CENTRAL SERIES is given by

$$\mathfrak{g}_0=\begin{bmatrix} 0 & b_{12} & b_{13} \\ 0 & 0 & b_{23} \\ 0 & 0 & 0 \end{bmatrix} \tag{3}$$

$$\mathfrak{g}_1=\begin{bmatrix} 0 & 0 & c_{13} \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \tag{4}$$

$$\mathfrak{g}_2=\begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}. \tag{5}$$

Any real nilpotent Lie group is DIFFEOMORPHIC to EUCLIDEAN SPACE. For instance, the group of matrices in the example above is diffeomorphic to $\mathbb{R}^3$, via the EXPONENTIAL MAPExponential Map (Lie Group). In general, the exponential map of a NILPOTENT LIE ALGEBRA is SURJECTIVE, in contrast to the more general SOLVABLE LIE GROUP.

See also BOREL GROUP, COMMUTATOR SERIES (LIE ALGEBRA), FLAG (VECTOR SPACE), LIE ALGEBRA, LIE GROUP, LOWER CENTRAL SERIES (LIE ALGEBRA), MATRIX, REPRESENTATION, REPRESENTATION (NILPOTENT LIE GROUP), SOLVABLE LIE ALGEBRA, SOLVABLE LIE GROUP, SPLIT SOLVABLE LIE ALGEBRA, UNIPOTENT

Nilpotent Matrix

There are two common definitions for a nilpotent matrix.

1. A SQUARE MATRIX whose EIGENVALUES are all 0.
2. A SQUARE MATRIX A such that A^n is the ZERO MATRIX 0 for some positive integer MATRIX POWER n, known as the index (Ayres 1962, p. 11).

See also EIGENVALUE, IDEMPOTENT MATRIX, MATRIX POLYNOMIAL, SQUARE MATRIX

Nim

A game, also called TACTIX, which is played by the following rules. Given one or more piles (NIM-HEAPS), players alternate by taking all or some of the counters in a single heap. The player taking the last counter or stack of counters is the winner. Nim-like games are

also called TAKE-AWAY GAMES and DISJUNCTIVE GAMES. If optimal strategies are used, the winner can be determined from any intermediate position by its associated NIM-VALUE.

Nim-Heap

A pile of counters in a game of NIM.

Nim-Sum

NIM-VALUE

Nim-Value

Every position of every IMPARTIAL GAME has a nim-value, making it equivalent to a NIM-HEAP. To find the nim-value (also called the SPRAGUE-GRUNDY NUMBER), take the MEX of the nim-values of the possible moves. The nim-value can also be found by writing the number of counters in each heap in binary, adding without carrying, and replacing the digits with their values mod 2. If the nim-value is 0, the position is SAFE; otherwise, it is UNSAFE. With two heaps, safe positions are (x, x) where $x \in [1, 7]$. With three heaps, (1, 2, 3), (1, 4, 5), (1, 6, 7), (2, 4, 6), (2, 5, 7), and (3, 4, 7).

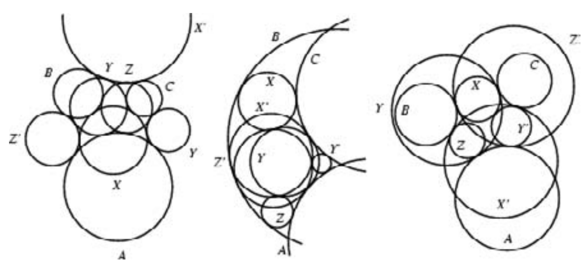
n-in-a-Row

TIC-TAC-TOE



Nine Associated Points Theorem

Any CUBIC CURVE that passes through eight of the nine intersections of two given cubic curves automatically passes through the ninth.

References

Evelyn, C. J. A.; Money-Coutts, G. B.; and Tyrrell, J. A. *The Seven Circles Theorem and Other New Theorems.* London: Stacey International, p. 15, 1974.

Nine Circles Theorem

Let A, B, and C be three circles in the plane, and let X be any circle touching B and C. Then build up a chain of circles such that $Y : CAX$, $Z : ABY$, $X' : BCZ$, $Y' : CAX'$, $Z' : ABY'$, $X'' : ABZ'$, where $C : C_1C_2C_3$ denotes a circle C tangent to circles C_1, C_2, and C_3. Although there are a number of choices for each successive tangent circle in the chain, if the choice at each stage is made appropriately, then the ninth and final circle X'' coincides with the first circle X (Evelyn *et al.* 1971, p. 58).

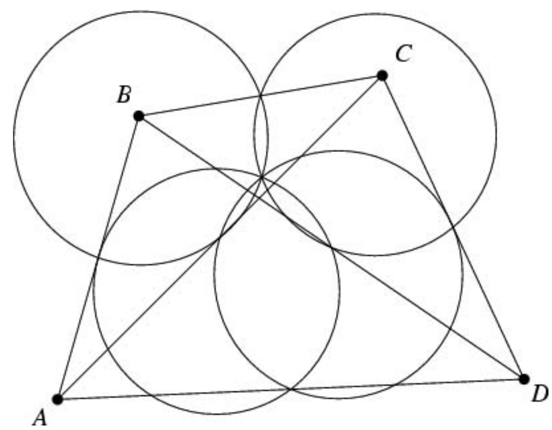
Nine-Point Circle



The CIRCLE, also called EULER'S CIRCLE and the FEUERBACH CIRCLE, which passes through the feet of the PERPENDICULAR F_A, F_B, and F_C dropped from the VERTICES of any TRIANGLE ΔABC on the sides opposite them. Euler showed in 1765 that it also passes through the MIDPOINTS M_A, M_B, M_C of the sides of ΔABC.

By FEUERBACH'S THEOREM, the nine-point circle also passes through the MIDPOINTS M_{HA}, M_{HB}, M_{HC} (now called the EULER POINTS) of the segments which join the VERTICES and the ORTHOCENTER H. These three triples of points make nine in all, giving the circle its name. The center F of the nine-point circle is called the NINE-POINT CENTER.

The RADIUS of the nine-point circle is $R/2$, where R is the CIRCUMRADIUS. The center of KIEPERT'S HYPERBOLA lies on the nine-point circle. The nine-point circle bisects any line from the ORTHOCENTER to a point on the CIRCUMCIRCLE. The nine-point circle of the INCENTER and EXCENTERS of a TRIANGLE is the CIRCUMCIRCLE.

There are four CIRCLES that are tangent all three sides (or their extensions) of a given TRIANGLE: the INCIRCLE I and three EXCIRCLES J_1, J_2, and J_3. These four circles are, in turn, all touched by the nine-point circle N.

Given four arbitrary points, the four nine-points circles of the triangles formed by taking three points at a times are CONCURRENT (Lemoine 1904; Wells 1991, p. 209; Schröder 1999). Moreover, if four points do not form an ORTHOCENTRIC SYSTEM, then there is a unique RECTANGULAR HYPERBOLA passing through them, and its center is given by the intersection of the nine-point circles of the points taken three at a time (Wells 1991, p. 209). Finally, the point of concurrence of the four nine-points circles is also the point of concurrence of the four circles determined by the feet of the perpendiculars (Schröder 1999).

The sum of the powers of the VERTICES with regard to the nine-point circle is

$$\tfrac{1}{4}\left(a_1^2+a_2^2+a_3^2\right).$$

Also,

$$\overline{FA_1}^2+\overline{FA_2}^2+\overline{FA_3}^2+\overline{FH}^2=3R^2,$$

where F is the NINE-POINT CENTER, A_i are the VERTICES, H is the ORTHOCENTER, and R is the CIRCUMRADIUS. All triangles inscribed in a given

CIRCLE and having the same ORTHOCENTER have the same nine-point circle.

Nine-Point Conic

A CONIC SECTION on which the MIDPOINTS of the sides of any COMPLETE QUADRANGLE lie. The three diagonal points also lie on this conic.

See also COMPLETE QUADRANGLE, CONIC SECTION, NINE-POINT CIRCLE

Nint

NEAREST INTEGER FUNCTION

Nint Zeta Function

Let

$$S_N(s) = \sum_{n=1}^{\infty} \left[(n^{1/N})\right]^{-s}, \tag{1}$$

where $[x]$ denotes NEAREST INTEGER FUNCTION, i.e, the INTEGER closest to x. For $s > 3$,

$$S_2(s) = 2\zeta(s-1) \tag{2}$$

$$S_3(s) = 3\zeta(s-2) + 4^{-s}\zeta(s) \tag{3}$$

$$S_4(s) = 4\zeta(s-3) + \zeta(s-1). \tag{4}$$

$S_N(n)$ is a POLYNOMIAL in π whose COEFFICIENTS are ALGEBRAIC NUMBERS whenever $n-N$ is ODD. The first few values are given explicitly by

$$S_3(4) = \frac{\pi^2}{2} + \frac{\pi^4}{23046} \tag{5}$$

$$S_5(6) = \frac{5\pi^2}{6} + \frac{\pi^4}{36} + \frac{\pi^6}{4^{12}} \times \left(\frac{1}{945} - \frac{170912 + 49928\sqrt{2}}{25}\sqrt{1-\sqrt{\frac{1}{2}}}\right) \tag{6}$$

$$S_6(7) = \pi^2 + \frac{\pi^4}{18} + \frac{\pi^6}{2520} + \frac{246013 + 353664\sqrt{2}}{45}\frac{\pi^7}{2^{27}}. \tag{7}$$

Nirenberg's Conjecture

If the GAUSS MAP of a COMPLETE MINIMAL SURFACE omits a NEIGHBORHOOD of the SPHERE, then the surface is a PLANE. This was proven by Osserman (1959). Xavier (1981) subsequently generalized the result as follows. If the GAUSS MAP of a complete MINIMAL SURFACE omits ≥ 7 points, then the surface is a PLANE.

Niven Number

Harshad Number

Niven's Constant

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Given a positive integer $m > 1$, let its prime factorization be written

$$m = p_1^{a_1} p_2^{a_2} p_3^{a_3} \cdots p_k^{a_k}. \tag{1}$$

Define the functions $h(n)$ and $H(n)$ by $h(1) = 1$, $H(1) = 1$, and

$$h(m) = \min(a_1, a_2 \ldots, a_k) \tag{2}$$

$$H(m) = \max(a_1, a_2 \ldots, a_k) \tag{3}$$

Then

$$\lim_{n\to\infty} \frac{1}{n} \sum_{m=1}^{n} h(m) = 1 \tag{4}$$

$$\lim_{n\to\infty} \frac{\sum_{m=1}^{n} h(m) - n}{\sqrt{n}} = \frac{\zeta\left(\frac{3}{2}\right)}{\zeta(3)}, \tag{5}$$

where $\zeta(z)$ is the Riemann zeta function (Niven 1969). Niven (1969) also proved that

$$\lim_{n\to\infty} \frac{1}{n} \sum_{m=1}^{n} H(m) = C, \tag{6}$$

where

$$C = 1 + \left\{ \sum_{j=2}^{\infty} \left[1 - \frac{1}{\zeta(j)} \right] \right\} = 1.705221\ldots \tag{7}$$

(Sloane's A033150).

The continued fraction of Niven's constant is 1, 1, 2, 2, 1, 1, 4, 1, 1, 3, 4, 4, 8, 4, 1, ... (Sloane's A033151). The positions at which the digits 1, 2, ... first occur in the continued fraction are 1, 3, 10, 7, 47, 41, 34, 13, 140, 252, 20, ... (Sloane's A033152). The sequence of largest terms in the continued fraction is 1, 2, 4, 8, 11, 14, 29, 372, 559, ... (Sloane's A033153), which occur at positions 1, 3, 7, 13, 20, 35, 51, 68, 96, ... (Sloane's A033154).

Noble Number

A noble number is defined as an irrational number which has a continued fraction which becomes an infinite sequence of 1s at some point,

$$\nu \equiv [a_1, a_2, \ldots, a_n, \bar{1}].$$

The prototype is the golden ratio ϕ whose continued fraction is composed *entirely* of 1s, $[\bar{1}]$. Any noble number can be written as

$$v = \frac{A_n + \phi A_{n-1}}{B_n + \phi B_{n+1}},$$

where A_k and B_k are the NUMERATOR and DENOMINATOR of the kth CONVERGENT of $[a_1, a_2, \ldots, a_n]$. The noble numbers are a SUBFIELD of $\mathbb{Q}(\sqrt{5})$.

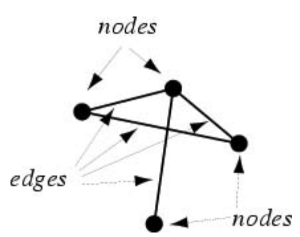
Node (Algebraic Curve)



ORDINARY DOUBLE POINT

Node (Fixed Point)

A FIXED POINT for which the STABILITY MATRIX has both EIGENVALUES of the same sign (i.e., both are POSITIVE or both are NEGATIVE). If $\lambda_1 < \lambda_2 < 0$, then the node is called STABLE; if $\lambda_1 < \lambda_2 < 0$, then the node is called an UNSTABLE NODE.

See also STABLE NODE, UNSTABLE NODE

Node (Graph)

A synonym for a VERTEX of a GRAPH, i.e., one of the points on which the graph may is defined and which may be connected by EDGES. The terms "point," "junction," and 0-simplex are also used (Harary 1994; Skiena 1990, p. 80).

The following tables gives the total numbers of nodes for various classes of graphs on $n = 1$, 2, ... nodes.

graph type	Sloane	total node count for $n = 1$, 2, ...nodes
GRAPH	A055543	1, 4, 12, 44, 170, 936, ...
TREE	A055544	1, 2, 3, 8, 15, 36, 77, 184 ...
LABELED TREE	A000169	1, 2, 9, 64, 625, ...
ROOTED TREE	A055545	1, 2, 6, 16, 45, 120, ...

Noetherian Module

A MODULE M is Noetherian if every submodule is finitely generated.

See also NOETHERIAN RING

Noetherian Ring

An abstract commutative RING satisfying the abstract chain condition.

See also LOCAL RING, NOETHER-LASKER THEOREM

Noether-Lasker Theorem

Let M be a finitely generated MODULE over a commutative NOETHERIAN RING R. Then there exists a finite set $\{N_i | 1 \le i \le l\}$ of submodules of M such that

1. $\bigcap_{i=1}^{l} N_i = 0$ and $\bigcap_{i \neq i_0} N_i$ is not contained in N_{i_0} for all $1 \le i_0 \le l$.
2. Each quotient M/N_i is primary for some prime P_i.
3. The P_i are all distinct for $1 \le i \le l$.
4. Uniqueness of the primary component N_i is equivalent to the statement that P_i does not contain P_j for any $j \neq i$.

Noether's Fundamental Theorem

If two curves ϕ and ψ of MULTIPLICITIES $r_i \neq 0$ and $s_i \neq 0$ have only ordinary points or ordinary singular points and CUSPS in common, then every curve which has at least MULTIPLICITY

$$r_i + s_i - 1$$

at every point (distinct or infinitely near) can be written

$$f \equiv \phi\psi' + \psi\phi' = 0,$$

where the curves ϕ' and ψ' have MULTIPLICITIES at least $r_i - 1$ and $s_i - 1$.

Noether's Symmetry Theorem

An extremely powerful theorem in physics which states that each SYMMETRY of a system leads to a physically conserved quantity. SYMMETRY under TRANSLATION corresponds to momentum conservation, SYMMETRY under ROTATION to angular momentum conservation, SYMMETRY in time to energy conservation, etc.

See also SYMMETRY

Noether's Transformation Theorem

Any irreducible curve may be carried by a factorable CREMONA TRANSFORMATION into one with none but ordinary singular points.

References

Coolidge, J. L. *A Treatise on Algebraic Plane Curves.* New York: Dover, p. 207, 1959.

Noise

An error which is superimposed on top of a true signal. Noise may be random or systematic. Noise can be greatly reduced by transmitting signals digitally instead of in analog form because each piece of information is allowed only discrete values which are spaced farther apart than the contribution due to noise.

CODING THEORY studies how to encode information efficiently, and ERROR-CORRECTING CODES devise methods for transmitting and reconstructing information in the presence of noise.

Noise Sphere

A mapping of RANDOM NUMBER TRIPLES to points in SPHERICAL COORDINATES according to

$$\theta = 2\pi X_n$$

$$\phi = \pi X_{n+1}$$

$$r = \sqrt{X_{n+2}}$$

in order to detect unexpected structure indicating correlations between triples. When such structure is present (note that this does *not* include the expected bunching of points along the z-axis according to the factor $\sin \phi$ in the spherical volume element), numbers may not be truly RANDOM.

Nome

Given a JACOBI THETA FUNCTION, the nome is defined

as

$$q(k) \equiv e^{\pi i \tau} = e^{-\pi K'(k)/K(k)} = e^{-\pi K\left(\sqrt{1-k^2}\right)/K(k)} \quad (1)$$

(Borwein and Borwein 1987, pp. 41, 109 and 114), where τ is the HALF-PERIOD RATIO, $K(k)$ is the complete ELLIPTIC INTEGRAL OF THE FIRST KIND, $m = k^2$ is the PARAMETER, and k is the MODULUS. The nome is implemented in *Mathematica* as `EllipticNomeQ[m]`.

Various notations for JACOBI THETA FUNCTIONS involving the nome include

$$\vartheta_i(z, q) \equiv \vartheta(z|\tau), \quad (2)$$

where τ is the HALF-PERIOD RATIO (Whittaker and Watson 1972, p. 464) and

$$\vartheta_i \equiv \vartheta(0, q). \quad (3)$$

Nomograph

NOMOGRAM

Non-Abelian

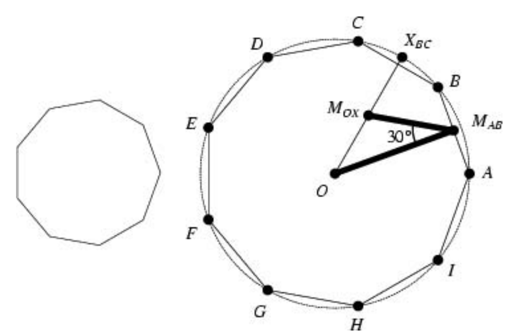
A GROUP or other algebraic object is called non-Abelian is the law of commutativity does not always hold, i.e., if the object is not ABELIAN. For example, the group of INVERTIBLE MATRICES is non-Abelian, as can be seen by comparing

$$\begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \quad (1)$$

and

$$\begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} = \begin{bmatrix} 0 & -1 \\ -1 & 0 \end{bmatrix}. \quad (2)$$

See also ABELIAN, ABELIANIZATION, GROUP, RING



Nonadjacent Vertex Pairs

The following table gives the number of nonadjacent vertex pairs k on graphs of $n = 1, 2, \ldots$ vertices.

k	counts
1	0, 1, 1, 1, 1, 1, 1, ...
2	0, 0, 1, 2, 2, 2, 2, ...
3	0, 0, 1, 3, 4, 5, 5, ...
4	0, 0, 0, 2, 6, 9, 10, ...
5	0, 0, 0, 1, 6, 15, 21, ...

See also ORE GRAPH

Nonagon

A 9-sided polygon, also known as an enneagon. Although the term "enneagon" is perhaps preferable (since it uses the Greek prefix and suffix instead of the mixed Roman/Greek nonagon), the term "nonagon," which is simpler to spell and pronounce, is used in this work. The REGULAR POLYGON with nine sides and SCHLÄFLI SYMBOL $\{9\}$.

The nonagon cannot be constructed using the classical Greek rules of GEOMETRIC CONSTRUCTION, but

Conway and Guy (1996) give a NEUSIS CONSTRUCTION based on TRISECTION. Madachy (1979) illustrates how to construct a nonagon by folding and knotting a strip of paper. Although the regular nonagon is not a CONSTRUCTIBLE POLYGON, Dixon (1991) gives constructions for several angles which are close approximations to the nonagonal angle $360^\circ/9 = 2\pi/9$, including angles of $\tan^{-1}(5/6) \approx 39.805571^\circ$ and $2\tan^{-1}((\sqrt{3}-1)/2) \approx 40.207819^\circ$.

Given a regular nonagon, let M_{AB} be the MIDPOINT of one side, X_{BC} be the MID-ARC POINT of the arc connecting an adjacent side, and M_{OX} the MIDPOINT of OX_{BC}. Then, amazingly, $\angle OM_{AB}M_{OX} = 30^\circ$ (Karst, quoted in Bankoff and Garfunkel 1973).

Nonagonal Heptagonal Number

A number which is simultaneously a NONAGONAL NUMBER N_m and HEPTAGONAL NUMBER Hep_n and therefore satisfies the DIOPHANTINE EQUATION

$$\tfrac{1}{2}m(7m-5) = \tfrac{1}{2}n(5n-4). \qquad (1)$$

COMPLETING THE SQUARE and rearranging gives

$$(14n-5)^2 - 7(10m-3)^2 = 62. \qquad (2)$$

Defining $x = 14n-5$ and $y = 10m-3$ gives the Pell-like equation

$$x^2 - 7y^2 = 62. \qquad (3)$$

The first integral solutions in m and n are $(m, n) =$ (1, 1), (88, 104), (12445, 14725), (1767052, 2090804), ... (Sloane's A048919 and A048920), giving the nonagonal heptagonal numbers 1, 26884, 542041975, 10928650279834, ... (Sloane's A048921).

See also HEPTAGONAL NUMBER, NONAGONAL NUMBER

References

Sloane, N. J. A. Sequences A048919, A048920, and A048921 in "An On-Line Version of the Encyclopedia of Integer Sequences." http://www.research.att.com/~njas/sequences/eisonline.html.

Nonagonal Hexagonal Number

A number which is simultaneously a NONAGONAL NUMBER N_m and HEXAGONAL NUMBER Hex_n and therefore satisfies the DIOPHANTINE EQUATION

$$\tfrac{1}{2}m(7m-5) = n(2n-1). \qquad (1)$$

COMPLETING THE SQUARE and rearranging gives

$$(14n-5)^2 - 7(4m-1)^2 = 18. \qquad (2)$$

Defining $x = 14n-5$ and $y = 4m-1$ gives the Pell-like equation

$$x^2 - 7y^2 = 18. \qquad (3)$$

This has fundamental solutions $(x, y) = (5, 1)$, (9, 3), and (19, 17), giving the family of solutions (5, 1), (9, 3), (19, 17), (61, 23), (135, 51), (509, 193), ... These give solutions which are integers in m and n of $(m, n) = (1, 1)$, (10, 13), (39025, 51625), ... (Sloane's A048916 and A048917), giving the nonagonal hexagonal numbers 1, 325, 5330229625,1353857339341, 22184715227362706161, ... (Sloane's A048918).

See also NONAGONAL NUMBER

Nonagonal Number

A FIGURATE NUMBER OF THE FORM $n(7n-5)/2$, also called an ENNEAGONAL NUMBER. The first few are 1, 9, 24, 46, 75, 111, 154, 204, ... (Sloane's A001106).
The first few odd nonagonal numbers are 1, 9, 75, 11, 261, 325, ... (Sloane's A028991), and the first few even nonagonal numbers are 24, 46, 154, 204, 396, ... (Sloane's A028992).

See also FIGURATE NUMBER, NONAGONAL HEPTAGONAL NUMBER, NONAGONAL HEXAGONAL NUMBER, NONAGONAL OCTAGONAL NUMBER, NONAGONAL PENTAGONAL NUMBER, NONAGONAL SQUARE NUMBER, NONAGONAL TRIANGULAR NUMBER, POLYGONAL NUMBER

Integer Sequences." http://www.research.att.com/~njas/sequences/eisonline.html.

Nonagonal Octagonal Number

A number which is simultaneously a NONAGONAL NUMBER N_m and OCTAGONAL NUMBER O_n and therefore satisfies the DIOPHANTINE EQUATION

$$\tfrac{1}{2}m(7m-5) = n(3n-2). \quad (1)$$

COMPLETING THE SQUARE and rearranging gives

$$(14n-5)^2 - 56(3m-1)^2 = 19. \quad (2)$$

Defining $x = 14n - 5$ and $y = 3m - 1$ gives the Pell-like equation

$$3x^2 - 56y^2 = 19. \quad (3)$$

The first integral solutions in m and n are $(m, n) = (1, 1)$, (425, 459), (286209, 309141), (192904201, 208360351), ... (Sloane's A048922 and A048923), giving the nonagonal octagonal numbers 1, 631125, 286703855361, 130242107189808901, ... (Sloane's A048924).

Nonagonal Pentagonal Number

A number which is simultaneously a NONAGONAL NUMBER N_m and PENTAGONAL NUMBER P_n and therefore satisfies the DIOPHANTINE EQUATION

$$\tfrac{1}{2}m(7m-5) = \tfrac{1}{2}n(3n-1). \quad (1)$$

COMPLETING THE SQUARE and rearranging gives

$$3(14n-5)^2 - 7(6m-1)^2 = 68. \quad (2)$$

Defining $x = 14n - 5$ and $y = 6m + 1$ gives the Pell-like equation

$$3x^2 - 7y^2 = 68. \quad (3)$$

This has solutions in (x, y) corresponding to solutions which are integral in m and n of $(m, n) = (1, 1)$, (14, 21), (7189, 10981), (165026, 252081), (86968201, 132846121), ... (Sloane's A048913 and A048914), giving the nonagonal pentagonal numbers 1, 651, 180868051, 95317119801, 26472137730696901, ... (Sloane's A048915).

Nonagonal Square Number

A number which is simultaneously a NONAGONAL NUMBER N_m and a SQUARE NUMBER S_n and therefore satisfies the DIOPHANTINE EQUATION

$$\tfrac{1}{2}m(7m-5) = n^2. \quad (1)$$

COMPLETING THE SQUARE and rearranging gives

$$(14n-5)^2 - 56m^2 = 25. \quad (2)$$

Defining $x = 14n - 5$ and $y = 2m^2$ gives the Pell-like equation

$$x^2 - 14y^2 = 25. \quad (3)$$

This has unit solutions $(x, y) = (9, 2)$, (23, 6), and (75, 20), which lead to the family of solutions (9, 2), (23, 6), (75, 20), (247, 66), (681, 182), (2245, 600), ... The corresponding integer solutions in n and m are $(n, m) = (1, 1)$, (2, 3), (18, 33), (49, 91), (529, 989), ... (Sloane's A048910 and A048911), giving the nonagonal square numbers 1, 9, 1089, 8281, 978121, 7436529, ... (Sloane's A048912).

Nonagonal Triangular Number

A number which is simultaneously a NONAGONAL NUMBER N_m and a TRIANGULAR NUMBER T_n and therefore satisfies the DIOPHANTINE EQUATION.

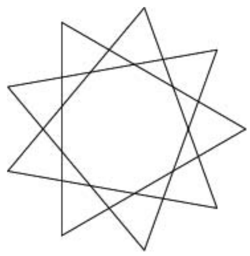
$$\tfrac{1}{2}m(7m-5) = \tfrac{1}{2}n(1+n). \quad (1)$$

COMPLETING THE SQUARE and rearranging gives

$$(14n-5)^2 - 7(2m+1)^2 = 18. \quad (2)$$

Defining $x = 14n - 5$ and $y = 2m + 1$ gives the Pell-like equation

$$x^2 - 7y^2 = 18. \quad (3)$$



This has unit solutions $(x, y) = (5, 1)$, (9, 3), and (19, 7), which lead to the family of solutions (5, 1), (9, 3), (19, 7), (61, 23), (135, 51), (299, 113), (971, 367), ... The corresponding integer solutions in n and m are $(n, m) = (1, 1)$, (10, 25), (154, 406), (2449, 6478), ... (Sloane's A048907 and A048908), giving the nonagonal triangular numbers 1, 325, 82621, 20985481, 5330229625, 1353857339341, ... (Sloane's A048909).

Nonagram

The STAR FIGURE $\{9/3\}$ composed of three EQUILATERAL TRIANGLES rotated at angles $0°$, $40°$, and $80°$. It has been called the STAR OF GOLIATH by analogy with the STAR OF DAVID (HEXAGRAM).

See also HEXAGRAM, NONAGON, STAR FIGURE, TRIGONOMETRY VALUES PI/9

Nonahedral Graph

A POLYHEDRAL GRAPH having nine vertices. There are 2606 nonisomorphic nonahedral graphs, as first enumerated by Federico (1969; Duijvestijn and Federico 1981).

See also NONAHEDRON, POLYHEDRAL GRAPH

References

Nonahedron

A nine-faced POLYHEDRON. There are 2606 topologically distinct convex nonahedra, corresponding to the 2606 nonisomorphic NONAHEDRAL GRAPHS.

See also NONAHEDRAL GRAPH

Nonalternating Knot

A KNOT which is not ALTERNATING. Unlike alternating knots, FLYPE moves are *not* sufficient to pass between all minimal diagrams of a given nonalternating knot (Hoste *et al.* 1998). In fact, Thistlethwaite used 13 different moves in generating a list of 16-crossing alternating knots (Hoste *et al.* 1998), and still had 9,868 duplicates out of a list of 1,018,774 knots (Hoste *et al.* 1998).

Nonassociative Algebra

An ALGEBRA which does not satisfy

$$a(bc) = (ab)c$$

is called a nonassociative algebra.

See also ALGEBRA, CAYLEY NUMBER, COMPLEX NUMBER, DIVISION ALGEBRA, QUATERNION, REAL NUMBER

References

Nonassociative Product

The number of nonassociative n-products with k elements preceding the rightmost left parameter is

$$F(n,k) = F(n-1,k) + F(n-1,k-1)$$

$$= \binom{n+k-2}{k} - \binom{n+k-1}{k-1}$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT. The number of n-products in a nonassociative algebra is

$$F(n) = C_n = \sum_{j=0}^{n-2} F(n,j) = \frac{(2n-2)!}{n!(n-1)!},$$

where C_n is a CATALAN NUMBER, 1, 1, 2, 5, 14, 42, 132, ... (Sloane's A000108).

Nonaveraging Sequence

N.B. A detailed online essay by S. Finch was the starting point for this entry.

A sequence of POSITIVE INTEGERS

$$1 \leq a_1 < a_2 < a_3 \ldots$$

is a nonaveraging sequence if it contains no three terms which are in an ARITHMETIC PROGRESSION, i.e., terms such that

$$\tfrac{1}{2}(a_i + a_j) = a_k$$

for distinct a_i, a_j, a_k. The EMPTY SET and sets of length one are therefore trivially nonaveraging.

Consider all possible subsets on the integers $S_n = \{1, 2, \ldots, n\}$. There is one nonaveraging sequence on S_0 ($\varnothing$), two on S_1 ($\varnothing$ and $\{1\}$), four on S_2, and so on. For example, 13 of the 16 subjects of S_4 are nonaveraging, with $\{1, 2, 3\}$, $\{2, 3, \}$, and $\{1, 2, 3, 4\}$ excluded. The numbers of nonaveraging subsets on S_0, S_1, ... are 1, 2, 4, 7, 13, 23, 40, ... (Sloane's A051013).

Wróblewski (1984) showed that for infinite nonaveraging sequences,

$$S(A) \equiv \sup_{\text{all nonaveraging sequences}} \sum_{k=1}^{\infty} \frac{1}{a^k} > 3.00849.$$

Noncentral Distribution

CHI-SQUARED DISTRIBUTION, F-DISTRIBUTION, STUDENT'S T-DISTRIBUTION

Noncommutative Group

A group whose elements do not commute. The simplest noncommutative GROUP is the DIHEDRAL GROUP D_3 of ORDER six.

See also COMMUTATIVE, FINITE GROUP D_3, GROUP

Noncommutative Ring

This entry contributed by VIKTOR BENGTSSON

A noncommutative ring R is a RING in which the law of multiplicative commutativity is not satisfied, i.e.,

$$a \cdot b \neq b \cdot a$$

for any two elements $a, b \in R$. In such a case, the elements a and b of the ring R are said not to commute. An important example of a noncommutative ring is the ring $\mathrm{M_n}(K)$ consisting of all $n \times n$ matrices whose elements are members of the FIELD K.

See also RING

Nonconformal Map

Let γ be a path in $\mathbb{C}$, $w = f(z)$, and θ and ϕ be the tangents to the curves γ and $f(\gamma)$ at z_0 and w_0. If there is an N such that

$$f^{(N)}(z_0) \neq 0 \tag{1}$$

$$f^{(N)}(z_0) = 0 \tag{2}$$

for all $n < N$ (or, equivalently, if $f'(z)$ has a zero of order $N-1$), then

$$f(z) = f(z_0) + \frac{f^{(N)}(z_0)}{N!} \times (z-z_0)^N + \frac{f^{(N+1)}(z_0)}{(N+1)!}(z-z_0)^{N+1} + \cdots \tag{3}$$

$$f(z) - f(z_0) = (z-z_0)^N \left[\frac{f(N)(z_0)}{N!} + \frac{f^{(N+1)}(z_0)}{(N+1)!}(z-z_0) + \cdots\right], \tag{4}$$

so the ARGUMENT is

$$\arg[f(z) - f(z_0)] = N \arg(z-z_0) + \arg\left[\frac{f(N)(z_0)}{N!} + \frac{f^{(N+1)}(z_0)}{(N+1)!}(z-z_0) + \ldots\right]. \tag{5}$$

As $z \to z_0$, $\arg(z-z_0) \to \theta$ and $|\arg[f(z) - f(z_0)]| \to \phi$,

$$\phi = N\theta + \arg\left[\frac{f(N)(z_0)}{N!}\right] = N\theta + \arg[f(N)(z_0)]. \tag{6}$$

See also CONFORMAL MAPPING

Nonconstructive Proof

A PROOF which indirectly shows a mathematical object exists without providing a specific example or algorithm for producing an example. Nonconstructive proofs are also called existence proofs.

See also EXISTENCE PROBLEM, PROOF

References

Courant, R. and Robbins, H. "The Indirect Method of Proof." §2.4.4 in *What is Mathematics?: An Elementary Approach to Ideas and Methods, 2nd ed.* Oxford, England: Oxford University Press, pp. 86–87, 1996.
Hoffman, P. *The Man Who Loved Only Numbers: The Story of Paul Erdos and the Search for Mathematical Truth.* New York: Hyperion, p. 229, 1998.

Noncototient

A POSITIVE value of n for which $x - \phi(x) = n$ has no solution, where $\phi(x)$ is the TOTIENT FUNCTION. The first few are 10, 26, 34, 50, 52, ... (Sloane's A005278).

Noncylindrical Ruled Surface

A RULED SURFACE parameterization $\mathbf{x}(u,v) = \mathbf{b}(u) + v\mathbf{g}(u)$ is called noncylindrical if $\mathbf{g} \times \mathbf{g}'$ is nowhere 0. A noncylindrical ruled surface always has a parameterization OF THE FORM

$$\mathbf{x}(u,v) = \boldsymbol{\sigma}(u) + v\boldsymbol{\delta}(u),$$

where $|\boldsymbol{\delta}|=1$ and $\boldsymbol{\sigma}' \cdot \boldsymbol{\delta}' = 0$, where $\boldsymbol{\sigma}$ is called the STRICTION CURVE of $\mathbf{x}$ and $\boldsymbol{\delta}$ the DIRECTOR CURVE.

See also DISTRIBUTION PARAMETER, RULED SURFACE, STRICTION CURVE

References

Nondecreasing Function

A function $f(x)$ is said to be nondecreasing on an INTERVAL I if $f(b) \geq f(a)$ for all $b > a$, where $a, b \in I$. Conversely, a function $f(x)$ is said to be nonincreasing on an INTERVAL I if $f(b) \leq f(a)$ for all $b > a$ with $a, b \in I$.

Nondividing Set

A SET in which no element divides the SUM of any nonempty subset of the other elements. The EMPTY SET and sets of length one are therefore trivially nondividing. Also, any set other than $\{1\}$ which contains 1 is dividing. For example, $\{2, 3, 5\}$ is dividing, since $2|(3+5)$ (and $5|(2+3)$), but $\{4, 6, 7\}$ is nondividing since 4 divides none of $\{6, 7, (6+7)\}$, and similarly for 6 and 7.

Consider all possible subsets on the integers $S_n = \{1, 2, \ldots, n\}$. Then the numbers of nondividing subsets on S_0, S_1, ... are 1, 2, 3, 5, 7, 12, 16, 28, 38, 60, ... (Sloane's A051014). For example, the 12 nondividing sets in S_6 are $\emptyset$, $\{1\}$, $\{2\}$, $\{3\}$, $\{4\}$, $\{5\}$, $\{6\}$, $\{2,3\}$, $\{2,5\}$, $\{3,4\}$, $\{3,5\}$, $\{4,5\}$, $\{4,6\}$, $\{5,6\}$, $\{3,4,5\}$, and $\{4,5,6\}$.

Nonequivalent

If $A \Rightarrow !B$ and $B \Rightarrow !A$ (i.e., $(A \Rightarrow !B) \wedge (B \Rightarrow !A)$, where $!A$ denotes NOT, $\Rightarrow$ denotes IMPLIES, and $\wedge$ denotes AND), then A and B are said to be inequivalent, a relationship which is written symbolically as $A \not\equiv B$, $A \not\Leftrightarrow B$, $A \not\rightleftharpoons B$ Nonequivalence is implemented in *Mathematica* as `Unequal[`A`, `B`, ...]`. Binary nonequivalence has the same TRUTH TABLE as XOR (i.e., EXCLUSIVE DISJUNCTION), reproduced below.

A	B	$A \not\equiv B$
T	T	F
T	F	T
F	T	T
F	F	F

See also CONNECTIVE, EQUIVALENT, EXCLUSIVE DISJUNCTION, XOR

Nonessential Singularity

REGULAR SINGULAR POINT

Non-Euclidean Geometry

In three dimensions, there are three classes of constant curvature GEOMETRIES. All are based on the first four of EUCLID'S POSTULATES, but each uses its own version of the PARALLEL POSTULATE. The "flat" geometry of everyday intuition is called EUCLIDEAN GEOMETRY (or PARABOLIC GEOMETRY), and the non-Euclidean geometries are called HYPERBOLIC GEOMETRY (or LOBACHEVSKY-BOLYAI-GAUSS GEOMETRY) and ELLIPTIC GEOMETRY (or RIEMANNIAN GEOMETRY). SPHERICAL GEOMETRY is a non-Euclidean 2-D geometry. It was not until 1868 that Beltrami proved that non-Euclidean geometries were as logically consistent as EUCLIDEAN GEOMETRY.

Nonincreasing Function

A function $f(x)$ is said to be nonincreasing on an INTERVAL I if $f(b) \leq f(a)$ for all $b > a$, where $a, b \in I$. Conversely, a function $f(x)$ is said to be nondecreasing on an INTERVAL I if $f(b) \geq f(a)$ for all $b > a$ with $a, b \in I$.

Noninvertible Knot

INVERTIBLE KNOT

Nonlinear Least Squares Fitting

Given a function $f(x)$ of a variable x tabulated at m values $y_1 = f(x_1)$, ..., $y_m = f(x_m)$, assume the function is of known analytic form depending on n parameters $f(x; \lambda_1, \ldots, \lambda_n)$, and consider the overdetermined set of m equations

$$y_1 = f(x_1; \lambda_1, \lambda_2, \ldots, \lambda_n) \tag{1}$$

$$y_m = f(x_m; \lambda_1, \lambda_2, \ldots, \lambda_n). \tag{2}$$

We desire to solve these equations to obtain the values λ_1, ..., λ_n which best satisfy this system of equations. Pick an initial guess for the λ_i and then define

$$d\beta_i = y_i - f(x_i; \lambda_1, \ldots, \lambda_n). \tag{3}$$

Now obtain a linearized estimate for the changes $d\lambda_i$ needed to reduce $d\beta_i$ to 0,

$$d\beta_i = \sum_{j=1}^{n} \frac{\partial f}{\partial \lambda_j} d\lambda_j \bigg|_{xj,\lambda} \tag{4}$$

for $i = 1$, ..., n. This can be written in component form as

$$d\beta_\mathrm{i} = A_{ij} d\lambda_{i,} \tag{5}$$

where A is the $m \times n$ MATRIX

$$A_{ij} = \begin{pmatrix} \frac{\partial f}{d\lambda_1}\Big|_{x_1,\lambda} & \frac{\partial f}{d\lambda_1}\Big|_{x_1,\lambda} & \cdots \\ \frac{\partial f}{d\lambda_2}\Big|_{x_2,\lambda} & \frac{\partial f}{d\lambda_2}\Big|_{x_2,\lambda} & \cdots \\ \vdots & \vdots & \ddots \\ \frac{\partial f}{d\lambda_1}\Big|_{x_m,\lambda} & \frac{\partial f}{d\lambda_n}\Big|_{x_m,\lambda} & \cdots \end{pmatrix}. \tag{6}$$

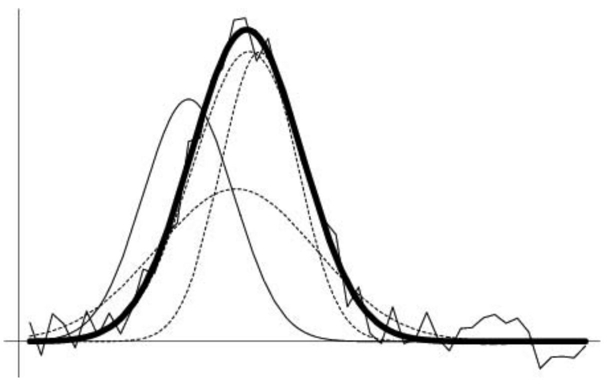
In more concise MATRIX form,

$$d\beta = \mathsf{A} d\lambda, \tag{7}$$

where $d\beta$ and $d\lambda$ are m-VECTORS. Applying the MATRIX TRANSPOSE of A to both sides gives

$$\mathsf{A}^\mathrm{T} d\beta = (\mathsf{A}^\mathrm{T}\mathsf{A}) d\lambda. \tag{8}$$

Defining



$$\mathbf{a} \equiv \mathsf{A}^\mathrm{T}\mathsf{A} \tag{9}$$

$$\mathbf{b} \equiv \mathsf{A}^{\mathrm{T}} d\beta \tag{10}$$

in terms of the known quantities A and $d\beta$ then gives the MATRIX EQUATION

$$\mathbf{a} d\lambda = \mathbf{b}, \tag{11}$$

which can be solved for $d\boldsymbol{\lambda}$ using standard matrix techniques such as GAUSSIAN ELIMINATION. This offset is then applied to λ and a new $d\beta$ is calculated. By iteratively applying this procedure until the elements of $d\boldsymbol{\lambda}$ become smaller than some prescribed limit, a solution is obtained. Note that the procedure may not converge very well for some functions and also that convergence is often greatly improved by picking initial values close to the best-fit value. The sum of square residuals is given by $R^2 = d\beta \cdot d\beta$ after the final iteration.

An example of a nonlinear least squares fit to a noisy GAUSSIAN FUNCTION

$$f(x; A, x_0, \sigma) = Ae^{-(x-x_0)^2/(2\sigma^2)} \tag{12}$$

is shown above, where the thin solid curve is the initial guess, the dotted curves are intermediate iterations, and the heavy solid curve is the fit to which the solution converges. The actual parameters are $(A, x_0, \sigma) = (1, 20, 5)$, the initial guess was (0.8, 15, 4), and the converged values are (1.03105, 20.1369, 4.86022), with $R^2 = 0.148461$. The PARTIAL DERIVATIVES used to construct the matrix A are

$$\frac{\partial f}{\partial A} = e^{-(x-x_0)^2/(2\sigma^2)} \tag{13}$$

$$\frac{\partial f}{\partial x_0} = \frac{A(x - x_0)}{\sigma^2} e^{-(x-x_0)^2/(2\sigma^2)} \tag{14}$$

$$\frac{\partial f}{\partial \sigma_0} = \frac{A(x - x_0)}{\sigma^3} e^{-(x-x_0)^2/(2\sigma^2)}. \tag{15}$$

The technique could obviously be generalized to multiple Gaussians, to include slopes, etc., although the convergence properties generally worsen as the number of free parameters is increased.

An analogous technique can be used to solve an overdetermined set of equations. This problem might, for example, arise when solving for the best-fit EULER ANGLES corresponding to a noisy ROTATION MATRIX, in which case there are three unknown angles, but nine correlated matrix elements. In such a case, write the n *different* functions as $f_i(\lambda_1, \ldots, \lambda_n)$ for $i = 1, \ldots, n$, call their actual values y_i, and define

$$\mathsf{A} = \begin{pmatrix} \left.\frac{\partial f_1}{\partial \lambda_1}\right|_{\lambda i} & \left.\frac{\partial f_1}{\partial \lambda_2}\right|_{\lambda i} & \cdots & \left.\frac{\partial f_1}{\partial \lambda_n}\right|_{\lambda i} \\ \vdots & \vdots & \ddots & \vdots \\ \left.\frac{\partial f_m}{\partial \lambda_1}\right|_{\lambda i} & \left.\frac{\partial f_m}{\partial \lambda_2}\right|_{\lambda i} & \cdots & \left.\frac{\partial f_m}{\partial \lambda_n}\right|_{\lambda i} \end{pmatrix}, \tag{16}$$

and

$$d\beta = \mathrm{y} - f_i(\lambda_1, \ldots, \lambda_n), \tag{17}$$

where λ_i are the numerical values obtained after the ith iteration. Again, set up the equations as

$$\mathsf{A} d\boldsymbol{\lambda} = d\beta, \tag{18}$$

and proceed exactly as before.

Nonnegative

A quantity which is either 0 (ZERO) or POSITIVE, i.e., ≥ 0.

See also NEGATIVE, NONNEGATIVE INTEGER, NONPOSITIVE, NONZERO, POSITIVE, ZERO

Nonnegative Integer

An INTEGER that is either 0 or positive, i.e., a member of the set $\mathbb{Z}^* = \{0\} \cup \mathbb{Z}^+$, where Z+ denotes the POSITIVE INTEGERS.

See also NEGATIVE INTEGER, NONPOSITIVE INTEGER, POSITIVE INTEGER, Z*

Nonnegative Partial Sum

The number of sequences with NONNEGATIVE partial sums which can be formed from n 1s and n -1s (Bailey 1996, Brualdi 1992) is given by the CATALAN NUMBERS. Bailey (1996) gives the number of NONNEGATIVE partial sums of n 1s and k -1s $a_1, a_2, \ldots, a_{n+k}$, so that

$$a_1 + a_2 + \ldots + a_i \geq 0 \tag{1}$$

for all $1 \leq i \leq n + k$. The closed form expression is

$$\left\{ n \atop 0 \right\} = 1 \quad (2)$$

for $n \geq 0$,

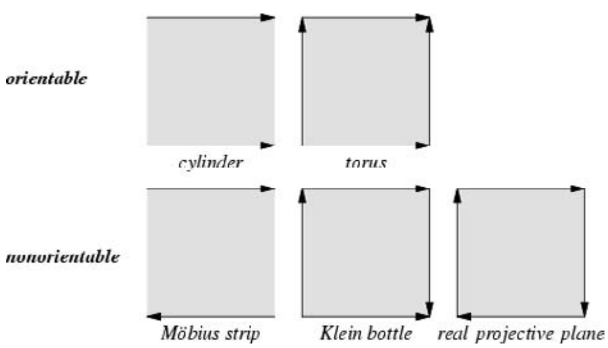
$$\left\{ n \atop 1 \right\} = n \quad (3)$$

for $n \geq 1$, and

$$\left\{ n \atop k \right\} = \frac{(n+1-k)(n+2)(n+3)\cdots(n+k)}{k!}, \quad (4)$$

for $n \geq k \geq 2$. Setting $k = n$ then recovers the CATALAN NUMBERS

$$C_n = \left\{ n \atop n \right\} = \frac{1}{n+1}\binom{2n}{n}. \quad (5)$$



See also CATALAN NUMBER

Nonorientable Surface

A surface such as the MÖBIUS STRIP or KLEIN BOTTLE (Gray 1997, pp. 322–323) on which there exists a closed path such that the directrix is reversed when moved around this path. The REAL PROJECTIVE PLANE is also a nonorientable surface, as are the BOY SURFACE, CROSS-CAP, and ROMAN SURFACE, all of which are homeomorphic to the REAL PROJECTIVE PLANE (Pinkall 1986).

There is a general method for constructing nonorientable surfaces which proceeds as follows (Banchoff 1984, Pinkall 1986). Choose three HOMOGENEOUS POLYNOMIALS of POSITIVE EVEN degree and consider the MAP

$$\mathbf{f} = (f_1(x,y,z), f_2(x,y,z), f_3(x,y,z)) : \mathbb{R}^3 \to \mathbb{R}^3. \quad (1)$$

Then restricting x, y, and z to the surface of a sphere by writing

$$x = \cos\theta \sin\phi \quad (2)$$

$$y = \sin\theta \sin\phi \quad (3)$$

$$z = \cos\phi \quad (4)$$

and restricting θ to $[0, 2\pi)$ and ϕ to $[0, \pi/2]$ defines a map of the REAL PROJECTIVE PLANE to $\mathbb{R}^3$.

In 3-D, there is no unbounded nonorientable surface which does not intersect itself (Kuiper 1961, Pinkall 1986).

Nonparametric Estimation

This entry contributed by EDGAR VAN TUYLL

Nonparametric estimation is a statistical method that allows the functional form of a fit to data to be obtained in the absence of any guidance or constraints from theory. As a result, the procedures of nonparametric estimation have no meaningful associated parameters. Two types of nonparametric techniques are artificial neural networks and kernel estimation.

Artificial neural networks model an unknown function by expressing it as a weighted sum of several sigmoids, usually chosen to be logit curves, each of which is a function of all the relevant explanatory variables. This amounts to an extremely flexible functional form for which estimation requires a nonlinear least-squares iterative search algorithm based on gradients.

Kernel estimation specifies $y = m(x) + e$, where $m(x)$ is the conditional expectation of y with no parametric form whatsoever, and the density of the error e is completely unspecified. The N observations y_i and x_i are used to estimate a joint density function for y and x. The density at a point (y_0, x_0) is estimated by seeing what proportion of the N observations are "close to" (y_0, x_0). This procedure involves the use of a function called a kernel to assign weights to nearby observations.

Nonseparable Graph

Biconnected Graph

Nonsingular Matrix

A square matrix that is not singular, i.e., one that has a matrix inverse. Nonsingular matrices are sometimes also called regular matrices. A square matrix is nonsingular iff its determinant is nonzero (Lipschutz 1991, p. 45). For example, there are 6 nonsingular 2×2 (0,1)-matrices:

$$\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 1 \\ 1 & 1 \end{bmatrix}, \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, \begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix}, \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}, \begin{bmatrix} 1 & 1 \\ 1 & 0 \end{bmatrix}.$$

The following table gives the numbers of nonsingular $n \times n$ matrices for certain matrix classes.

matrix type	Sloane	counts for $n = 1, 2, \ldots$
$(-1, 0, 1)$-matrices	A056989	2, 48, 11808, ...
$(-1, 1)$-matrices	A056990	2, 8, 192, 22272, ...
$(0, 1)$-matrices	A055165	1, 6, 174, 22560, ...

Nonsquarefree

Squareful

Nonstandard Analysis

Nonstandard analysis is a branch of mathematical logic which weakens the axioms of usual analysis to include only the first-order ones. It also introduces hyperreal numbers to allow for the existence of "genuine infinitesimals," numbers which are less than 1/2, 1/3, 1/4, 1/5, ..., but greater than 0. Abraham Robinson developed nonstandard analysis in the 1960s. The theory has since been investigated for its own sake and has been applied in areas such as Banach spaces, differential equations, probability theory, microeconomic theory, and mathematical physics.

Nonwandering

A point x in a MANIFOLD M is said to be nonwandering if, for every open NEIGHBORHOOD U of x, it is true that $\phi^{-n}U \cup U \neq \emptyset$ for a MAP ϕ for some $n > 0$. In other words, every point close to x has some iterate under ϕ which is also close to x. The set of all nonwandering points is denoted $\Omega(\phi)$, which is known as the nonwandering set of ϕ.

Nonzero

A quantity which does not equal ZERO is said to be nonzero. A REAL nonzero number must be either POSITIVE or NEGATIVE, and a COMPLEX nonzero number can have either REAL or IMAGINARY PART nonzero.

See also NEGATIVE, NONNEGATIVE, NONPOSITIVE, POSITIVE, ZERO

NOR

NOR gate

A PREDICATE in LOGIC equivalent to the composition NOT OR that yields FALSE if any condition is TRUE, and TRUE if all conditions are FALSE. A NOR B is equivalent to !(A ∨ B), where !A denotes NOT and ∨ denotes OR. In PROPOSITIONAL CALCULUS, the term JOINT DENIAL is used to refer to the NOR connective. Notations for NOR include $A \bar{\vee} B$ and $A \downarrow B$ (Mendelson 1997, p. 26). The NOR operation is implemented in *Mathematica* 4.1 as Nor[A, B, ...]. The circuit diagram symbol for a NOR gate is illustrated above. The BINARY NOR operator has the following TRUTH TABLE (Simpson 1987, p. 547; Mendelson 1997, p. 26).

A	B	$A \bar{\vee} B$
T	T	F
T	F	F
F	T	F
F	F	T

Norm

Given a n-D VECTOR

$$\mathbf{x} = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{bmatrix},$$

a VECTOR NORM $\|\mathbf{x}\|$ is a NONNEGATIVE number satisfying

1. $\|\mathbf{x}\| > 0$ when $\mathbf{x} \neq 0$ and $\|\mathbf{x}\| = 0$ IFF $\mathbf{x} = 0$,
2. $\|k\mathbf{x}\| = |k|\|\mathbf{x}\|$ for any SCALAR k,
3. $\|\mathbf{x} + \mathbf{y}\| \leq \|\mathbf{x}\| + \|\mathbf{y}\|$

The most common norm is the vector L2-NORM, defined by

$$\|\mathbf{x}\|_2 = |\mathbf{x}| = \sqrt{x_1^2 + x_2^2 + \cdots + x_n^2}.$$

Given a SQUARE MATRIX A, a MATRIX NORM $\|\mathsf{A}\|$ is a NONNEGATIVE number associated with A having the properties

1. $\|\mathsf{A}\| > 0$ when $\mathsf{A} \neq 0$ and $\|\mathsf{A}\| = 0$ IFF $\mathsf{A} = 0$,
2. $\|k\mathsf{A}\| = |k|\|\mathsf{A}\|$ for any SCALAR k,
3. $\|\mathsf{A} + \mathsf{B}\| \leq \|\mathsf{A}\| + \|\mathsf{B}\|$,
4. $\|\mathsf{AB}\| \leq \|\mathsf{A}\|\|\mathsf{B}\|$

Norm (Operator)

The operator norm of a LINEAR OPERATOR $T: V \to W$ is the largest value by which T stretches an element of V,

$$\|T\| = \sup_{\|v\|=1} \|T(v)\|. \tag{1}$$

It is necessary for V and W to be normed vector spaces. The operator norm of a composition is controlled by the norms of the operators,

$$\|TS\| \leq \|T\|\|S\| \tag{2}$$

When T is given by a matrix, say $T(v) = \mathsf{A}v$, then $\|T\|$ is the SQUARE ROOT of the largest EIGENVALUE of the SYMMETRIC MATRIX $\mathsf{A}^{\mathrm{T}}\mathsf{A}$, all of whose eigenvalues are nonnegative. For instance, if

$$A = \begin{bmatrix} 2 & 0 & 0 \\ 3 & 0 & 2 \end{bmatrix} \tag{3}$$

then

$$\mathsf{A}^{\mathrm{T}}\mathsf{A} = \begin{bmatrix} 13 & 0 & 6 \\ 0 & 0 & 0 \\ 6 & 0 & 4 \end{bmatrix}, \tag{4}$$

which has eigenvalues $\{0, 1, 16\}$, so $\|A\| = 4$.

The following *Mathematica* function will determine the operator norm of a matrix.

```
OperatorNorm[a_List?MatrixQ] :=
   Sqrt[Max[Eigenvalues[Transpose[a].a]]]
```

Norm Theorem

If a PRIME NUMBER divides a norm but not the bases of the norm, it is itself a norm.

Normal

NORMAL CURVE, NORMAL DISTRIBUTION, NORMAL DISTRIBUTION FUNCTION, NORMAL EQUATION, NORMAL FORM, NORMAL GROUP, NORMAL MAGIC SQUARE, NORMAL MATRIX, NORMAL NUMBER, NORMAL PLANE, NORMAL SUBGROUP, NORMAL VECTOR

Normal (Algebraically)

GALOISIAN

Normal Bundle

This entry contributed by RYAN BUDNEY

The normal bundle of a submanifold $N \in M$ is the VECTOR BUNDLE over N that consists of all pairs (x, v), where x is in N and v is a vector in the VECTOR QUOTIENT SPACE TxM/TxN. Provided M has a Riemann metric, TxM/TxN can be thought of as the orthogonal complement to $Tx \in TxM$.

Normal Curvature

Let $\mathbf{u_p}$ be a unit TANGENT VECTOR of a REGULAR SURFACE $M \subset \mathbb{R}^3$. Then the normal curvature of M in the direction $\mathbf{u_p}$ is

$$\kappa(\mathbf{u_p}) = S(\mathbf{u_p}) \cdot \mathbf{u_p}, \tag{1}$$

where S is the SHAPE OPERATOR. Let $M \subset \mathbb{R}^3$ be a REGULAR SURFACE, $\mathbf{p} \in M$, $\mathbf{x}$ be an injective REGULAR PATCH of M with $\mathbf{p} = \mathbf{x}(u_0, v_0)$, and

$$\mathbf{v_p} = a\mathbf{x}_u(u_0, v_0) + b\mathbf{x}_v(u_0, v_0), \tag{2}$$

where $\mathbf{v_p} \in M_p$. Then the normal curvature in the direction $\mathbf{v_p}$ is

$$\kappa(v\mathbf{p}) = \frac{ea^2 + 2fab + gb^2}{Ea^2 + 2Fab + Gb^2}, \tag{3}$$

where E, F, and G are the coefficients of the first FUNDAMENTAL FORM and e, f, and g are the coefficients of the second FUNDAMENTAL FORM.

The MAXIMUM and MINIMUM values of the normal curvature at a point on a REGULAR SURFACE are called the PRINCIPAL CURVATURES κ_1 and κ_2.

See also CURVATURE, FUNDAMENTAL FORMS, GAUSSIAN CURVATURE, MEAN CURVATURE, PRINCIPAL CURVATURES, SHAPE OPERATOR, TANGENT VECTOR

Normal Curve

GAUSSIAN DISTRIBUTION

Normal Developable

A RULED SURFACE M is a normal developable of a curve $\mathbf{y}$ if M can be parameterized by $\mathbf{x}(u,v)=\mathbf{y}(u)+v\hat{\mathbf{N}}(u)$, where $\mathbf{N}$ is the NORMAL VECTOR.

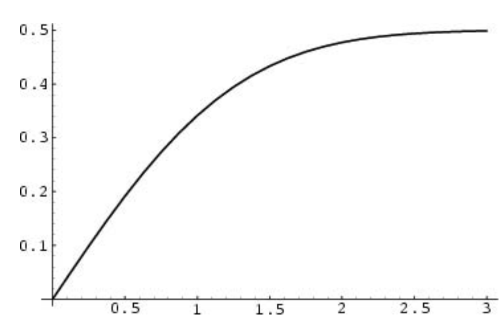
Normal Distribution

Another name for a GAUSSIAN DISTRIBUTION. Given a normal distribution in a VARIATE x with MEAN μ and VARIANCE σ^2,

$$P(x)dx=\frac{1}{\sigma\sqrt{2\pi}}e^{-(x-\mu)^2/2\sigma^2}dx,$$

the so-called "STANDARD NORMAL DISTRIBUTION" is given by taking $\mu=0$ and $\sigma^2=1$. An arbitrary normal distribution can be converted to a STANDARD NORMAL DISTRIBUTION by changing variables to $z\equiv(x-\mu)/\sigma$, so $dz=dx/\sigma$, yielding

$$P(x)dx=\frac{1}{\sqrt{2\pi}}e^{-z^2/2}dz.$$



Feller (1968) uses the symbol $\varphi(x)$ for P(x) in the above equation, but then switches to $\mathbf{n}(x)$ in Feller (1971). The FISHER-BEHRENS PROBLEM is the determination of a test for the equality of MEANS for two normal distributions with different VARIANCES.

See also FISHER-BEHRENS PROBLEM, GAUSSIAN DISTRIBUTION, HALF-NORMAL DISTRIBUTION, KOLMOGOROV-SMIRNOV TEST, NORMAL DISTRIBUTION FUNCTION, STANDARD NORMAL DISTRIBUTION, TETRACHORIC FUNCTION

Normal Distribution Function

A normalized form of the cumulative GAUSSIAN DISTRIBUTION function giving the probability that a

variate assumes a value in the range $[0, x]$,

$$\Phi(x) \equiv Q(x) \equiv \frac{1}{\sqrt{2\pi}} \int_0^x e^{-t^2/2} dt. \tag{1}$$

It is related to the PROBABILITY INTEGRAL

$$\alpha(x) \equiv \frac{1}{\sqrt{2\pi}} \int_{-x}^{x} e^{-t^2/2} dt. \tag{2}$$

by

$$\Phi(x) = \tfrac{1}{2}\alpha(x) \tag{3}$$

Let $u \equiv t/\sqrt{2}$ so $du = dt/\sqrt{2}$. Then

$$\Phi(x) = \frac{1}{\sqrt{\pi}} \int_0^{x/\sqrt{2}} e^{-u^2} du = \frac{1}{2} \operatorname{erf}\left(\frac{x}{\sqrt{2}}\right). \tag{4}$$

Here, ERF is a function sometimes called the error function. The probability that a normal variate assumes a value in the range $[x_1, x_2]$ is therefore given by

$$\Phi(x_1, x_2) = \frac{1}{2}\left[\operatorname{erf}\left(\frac{x^2}{\sqrt{2}}\right) - \operatorname{erf}\left(\frac{x_1}{\sqrt{2}}\right)\right]. \tag{5}$$

Neither $\Phi(z)$ nor ERF can be expressed in terms of finite additions, subtractions, multiplications, and ROOT EXTRACTIONS, and so must be either computed numerically or otherwise approximated.
Note that a function different from $\Phi(x)$ is sometimes defined as "the" normal distribution function

$$\mathfrak{N}(x) \equiv \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{x} e^{-t^2/2} dt \tag{6}$$

$$= \Phi(-\infty,\ x) \tag{7}$$

$$= \frac{1}{2} + \Phi(x) \tag{8}$$

$$= \frac{1}{2}\left[1 + \operatorname{erf}\left(\frac{x}{\sqrt{2}}\right)\right] \tag{9}$$

(Feller 1968; Beyer 1987, p. 551), although this function is less widely encountered than the usual $\Phi(x)$. The notation $\mathfrak{N}(x)$ is due to Feller (1971).

The value of a for which $P(x)$ falls within the interval $[-a, a]$ with a given probability P is a related quantity called the CONFIDENCE INTERVAL.

For small values $x \ll 1$, a good approximation to $\Phi(x)$ is obtained from the MACLAURIN SERIES for ERF,

$$\Phi(x) = \frac{1}{\sqrt{2\pi}}\left(x - \tfrac{1}{6}x^3 + \tfrac{1}{40}x^5 - \tfrac{1}{336}x^7 + \tfrac{1}{3456}x^9 + \ldots\right) \tag{10}$$

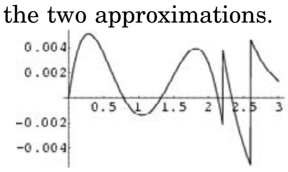
(Sloane's A014481). For large values $x \gg 1$, a good approximation is obtained from the asymptotic series for ERF,

$$\Phi(x) = \frac{1}{2} + \frac{e^{-x^2/2}}{2\sqrt{\pi}} \times \left(x^{-1} - x^{-3} + 3x^{-5} - 15x^{-7} + 105x^{-9} + \ldots\right) \tag{11}$$

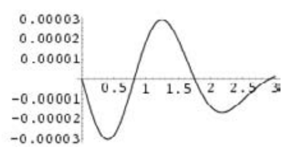
(Sloane's A001147).

The value of $\Phi(x)$ for intermediate x can be computed using the CONTINUED FRACTION identity

$$\int_0^x e^{-u^2} du = \frac{\sqrt{\pi}}{2} - \cfrac{\tfrac{1}{2}e^{-x^2}}{x + \cfrac{1}{2x + \cfrac{2}{x + \cfrac{3}{2x + \cfrac{4}{x + \ldots}}}}} \tag{12}$$



A simple approximation of $\Phi(x)$ which is good to two decimal places is given by



$$\Phi_1(x) \approx \begin{cases} 0.1x(4.4 - x) & \text{for } 0 \le x \le 2.2 \\ 0.49 & \text{for } 2.2 < x < 2.6 \\ 0.50 & \text{for } x \ge 2.6 \end{cases} \tag{13}$$

Abramowitz and Stegun (1972) and Johnson and Kotz (1970) give other functional approximations. An approximation due to Bagby (1995) is

$$\Phi_2(x) = \tfrac{1}{2}\{1 - \tfrac{1}{30}[7e^{-x^2/2} + 16e^{-x^2(2-\sqrt{2})} + (7 + \tfrac{1}{4}\pi x^2)e^{-x^2}]\}^{1/2} \tag{14}$$

The plots below show the differences between Φ and the two approximations.

The first QUARTILE of a standard NORMAL DISTRIBUTION occurs when

$$\int_0^t \Phi(z) dz = \tfrac{1}{4}. \tag{15}$$

The solution is $t = 0.6745\ldots$. The value of t giving $\frac{1}{4}$ is known as the PROBABLE ERROR of a normally distributed variate.

Normal Equation

Given an overdetermined MATRIX EQUATION

$$\mathsf{A}\mathbf{x} = \mathbf{b},$$

the normal equation is that which minimizes the sum of the square differences between left and right sides

$$\mathsf{A}^{\mathrm{T}}\mathsf{A}\mathbf{x} = \mathsf{A}^{\mathrm{T}}\mathbf{b}.$$

See also LEAST SQUARES FITTING, MOORE-PENROSE GENERALIZED MATRIX INVERSE, NONLINEAR LEAST SQUARES FITTING

Normal Form

A way of representing objects so that, although each may have many different names, every possible name corresponds to exactly one object (Petkovsek *et al.* 1996, p. 7). Koepf (1998, p. 2) defines normal form to mean the uniquely determined holonomic equation of lowest order up to multiplication by polynomials.

See also CANONICAL FORM

Normal Function

A SQUARE INTEGRABLE function $\phi(t)$ is said to be normal if

$$\int [\phi(t)]^2 dt = 1$$

However, the NORMAL DISTRIBUTION FUNCTION is also sometimes called "the normal function."

See also NORMAL DISTRIBUTION FUNCTION, SQUARE INTEGRABLE

References

Sansone, G. *Orthogonal Functions, rev. English ed.* New York: Dover, p. 6, 1991.

Normal Group

NORMAL SUBGROUP

Normal Line

A LINE along a NORMAL VECTOR (i.e., perpendicular to some TANGENT LINE).

If $K \subset \mathbb{R}^d$ is a CENTROSYMMETRIC SET which has a twice differentiable boundary, then there are $2d+2$ normals through the center (Croft *et al.* 1991, p. 15).

References

Croft, H. T.; Falconer, K. J.; and Guy, R. K. *Unsolved Problems in Geometry.* New York: Springer-Verlag, 1991.

Normal Magic Square

MAGIC SQUARE

Normal Matrix

A SQUARE MATRIX A is a normal matrix if

$$[\mathsf{A}, \mathsf{A}^*] = 0,$$

where $[a, b]$ is the COMMUTATOR and A^* denotes the ADJOINT MATRIX. For example, the matrix

$$\begin{bmatrix} i & 0 \\ 0 & 3-5i \end{bmatrix}$$

is a normal matrix, but is *not* a HERMITIAN MATRIX. A matrix m can be tested to see if it is normal using the *Mathematica* function

```
NormalQ[a_List?MatrixQ] := Module[
  {b = Conjugate@Transpose@a},
  a. b === b. a
 ]
```

The normal matrices are the matrices which are unitarily DIAGONALIZABLE. That is, A is a normal matrix iff there exists a UNITARY MATRIX U such that UAU^{-1} is a DIAGONAL MATRIX. All HERMITIAN MATRICES are normal, but they are restricted to real eigenvalues. A normal matrix has no restriction on its eigenvalues.

The following table gives the number of normal square matrices of given types for orders $n = 1, 2, ...$.

type	Sloane	counts
$(0, 1)$	A055547	2, 8, 68, 1124, ...
$(-1, 1)$	A055548	2, 12, 80, 2096, ...

$(-1, 0, 1)$	A055549	3, 33, 939, ...

See also ADJOINT MATRIX, DIAGONAL MATRIX, HERMITIAN MATRIX, UNITARY MATRIX

Normal Number

An IRRATIONAL NUMBER for which any FINITE pattern of numbers occurs with the expected limiting frequency in the expansion in a given base (or all bases). For example, for a normal decimal number, each digit 0–9 would be expected to occur 1/10 of the time, each pair of digits 00–99 would be expected to occur 1/100 of the time, etc.

Determining if numbers are normal is an unresolved problem. It is not even known if PI or E are normal. While tests of $\sqrt{n}$ for $n = 2$, 3, 5, 6, 7, 8, 10, 11, 12, 13, 14, 15 indicate that these SQUARE ROOTS may be normal (Beyer *et al.* 1970ab), normality of these numbers has also not been proven. Strangely enough, the only numbers known to be normal (in certain bases) are artificially constructed ones such as the CHAMPERNOWNE CONSTANT and the COPELAND-ERDOS CONSTANT.

See also CHAMPERNOWNE CONSTANT, COPELAND-ERDOS CONSTANT, E, PI

Normal Order

A function $f(n)$ has the normal order $F(n)$ if $f(n)$ is approximately $F(n)$ for ALMOST ALL values of n. More precisely, if

$$(1-\varepsilon)F(n) < f(n) < (1+\varepsilon)F(n)$$

for every positive ε and ALMOST ALL values of n, then the normal order of $f(n)$ is $F(n)$.

Normal Subgroup

Let H be a SUBGROUP of a GROUP G. Then H is a normal subgroup of G, written $H \triangleleft G$, if

$$xHx^{-1} = H$$

for every element x in G (Scott 1987, p. 25). Normal subgroups are also known as invariant subgroups.

See also GROUP, NORMAL SERIES, QUOTIENT GROUP, SUBGROUP

References

Scott, W. R. *Group Theory.* New York: Dover, 1987.

Normal to a Plane

NORMAL VECTOR

Normal Vector

The normal to a PLANE specified by

$$f(x,y,z) = ax + by + cz + d = 0 \quad (1)$$

is given by

$$\mathbf{N} = \nabla f = \begin{bmatrix} a \\ b \\ c \end{bmatrix}. \quad (2)$$

The normal vector at a point (x_0, y_0) on a surface $z = f(x,y)$ is

$$\mathbf{N} = \begin{bmatrix} f_x(x_0,y_0) \\ f_y(x_0,y_0) \\ -1 \end{bmatrix}. \quad (3)$$

In the PLANE, the unit normal vector is defined by

$$\hat{\mathbf{N}} \equiv \frac{d\hat{\mathbf{T}}}{d\phi}, \quad (4)$$

where $\hat{\mathbf{T}}$ is the unit TANGENT VECTOR and ϕ is the polar angle. Given a unit TANGENT VECTOR

$$\hat{\mathbf{T}} \equiv u_1\hat{\mathbf{x}} + u_2\hat{\mathbf{y}} \quad (5)$$

with $\sqrt{u_1^2 + u_2^2} = 1$, the normal is

$$\hat{\mathbf{N}} \equiv u_2\hat{\mathbf{x}} + u_1\hat{\mathbf{y}}. \quad (6)$$

For a function given parametrically by $(f(t), g(t))$, the normal vector relative to the point $(f(t), g(t))$ is therefore given by

$$x(t) = -\frac{g'}{\sqrt{f'^2 + g'^2}} \quad (7)$$

$$y(t) = \frac{f'}{\sqrt{f'^2 + g'^2}} \quad (8)$$

To actually place the vector normal to the curve, it must be displaced by $(f(t), g(t))$.

In 3-D SPACE, the unit normal is

$$\hat{\mathbf{N}} \equiv \frac{\frac{d\hat{\mathbf{T}}}{ds}}{\left|\frac{d\hat{\mathbf{T}}}{ds}\right|} = \frac{\frac{d\hat{\mathbf{T}}}{dt}}{\left|\frac{d\hat{\mathbf{T}}}{dt}\right|} = \frac{1}{\kappa}\frac{d\hat{\mathbf{T}}}{ds}, \quad (9)$$

where k is the CURVATURE. Given a 3-D surface $F(x,y,z) = 0$,

$$\hat{\mathbf{n}} = \frac{F_x + F_y + F_z}{\sqrt{F_x^2 + F_y^2 + F_z^2}}. \quad (10)$$

If the surface is defined parametrically in the form

$$x = x(\phi, \psi) \quad (11)$$

$$y = y(\phi, \psi) \quad (12)$$

$$z = z(\phi, \psi) \quad (13)$$

define the VECTORS

$$\mathbf{a} \equiv \begin{bmatrix} x_\phi \\ y_\phi \\ z_\phi \end{bmatrix} \quad (14)$$

$$\mathbf{b} \equiv \begin{bmatrix} x_\phi \\ y_\phi \\ z_\phi \end{bmatrix}. \quad (15)$$

Then the unit normal vector is

$$\hat{\mathbf{N}} = \frac{\mathbf{a} \times \mathbf{b}}{\sqrt{|\mathbf{a}|^2|\mathbf{b}|^2 - |\mathbf{a} \cdot \mathbf{b}|^2}} \quad (16)$$

Let g be the discriminant of the METRIC TENSOR. Then

$$\mathbf{N} = \frac{\mathbf{r}_1 \times \mathbf{r}_2}{\sqrt{g}} = \varepsilon_{ij} r^j. \quad (17)$$

Normalized Laplacian Matrix

LAPLACIAN MATRIX

Normalized Vector

The normalized vector of $\mathbf{X}$ is a VECTOR in the same direction but with NORM (length) 1. It is denoted $\hat{\mathbf{X}}$ and given by

$$\hat{\mathbf{X}} \equiv \frac{\mathbf{X}}{|\mathbf{X}|},$$

where $|\hat{X}|$ is the NORM of **X**. It is also called a UNIT VECTOR.

See also UNIT VECTOR

Normalizer

The set of elements g of a GROUP such that

$$g^{-1}Hg = H,$$

is said to be the normalizer $N_G(H)$ with respect to a subset of group elements H. If H is a SUBGROUP of G, $N_G(H)$ is also a SUBGROUP containing H.

See also CENTRALIZER, TIGHTLY EMBEDDED

Normed Space

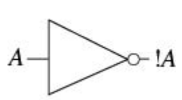
A VECTOR SPACE possessing a NORM.

Nosarzewska's Inequality

Given a convex PLANE region with AREA A and PERIMETER p,

$$A - \tfrac{1}{2}p < N \leq A + \tfrac{1}{2}p + 1,$$

where N is the number of enclosed LATTICE POINTS (Nosarzewska 1948). This improves on JARNICK'S INEQUALITY



$$|N - A| < p.$$

NOT

NOT gate

An CONNECTIVE in LOGIC which converts TRUE to FALSE and FALSE to TRUE. NOT A is denoted $!A$, $\neg A$, $\bar{A}$ (Simpson 1987, p. 537) or $\sim A$ (Carnap 1958, p. 7; Mendelson 1997, p. 12). The NOT operation is implemented in *Mathematica* as Not[A], or $!A$. The circuit diagram symbol for a NOT gate is illustrated above.

The NOT operation has the following TRUTH TABLE (Carnap 1958, p. 10; Simpson 1987, p. 546; Mendelson 1997, p. 12).

A	$!A$

Conway, J. H. and Guy, R. K. *The Book of Numbers.* New York: Springer-Verlag, p. 16, 1996.

NP-Problem

A problem is assigned to the NP (nondeterministic POLYNOMIAL time) class if it is solvable in polynomial time by a nondeterministic TURING MACHINE. (A nondeterministic TURING MACHINE is a "parallel" TURING MACHINE which can take many computational paths simultaneously, with the restriction that the parallel Turing machines cannot communicate.) A P-PROBLEM (whose solution time is bounded by a polynomial) is always also NP. If a problem is known to be NP, and a solution to the problem is somehow known, then demonstrating the correctness of the solution can always be reduced to a single P (POLYNOMIAL time) verification.

LINEAR PROGRAMMING, long known to be NP and thought *not* to be P, was shown to be P by L. Khachian in 1979. It is an important UNSOLVED PROBLEM to determine if all apparently NP problems are actually P.

A problem is said to be NP-HARD if an ALGORITHM for solving it can be translated into one for solving any other NP-problem. It is much easier to show that a problem is NP than to show that it is NP-HARD. A problem which is both NP and NP-HARD is called an NP-COMPLETE PROBLEM.

JACOBI ELLIPTIC FUNCTIONS

n-Sphere

HYPERSPHERE

NSW Number

An NSW number is a side length of a SQUARE the square of whose diagonal is one more than a SQUARE NUMBER. Such numbers were called "rational diag-

onals" by the Greeks (Wells 1986, p. 70). A formula for NSW numbers is given by

$$S(m)=\frac{(1+\sqrt{2})^m+(1-\sqrt{2})^m}{2}$$

for positive integers m. A RECURRENCE RELATION for $S(m)$ is given by

$$S(n)=6S(n-1)-S(n-2) \tag{1}$$

with $S(1)=1$ and $S(2)=7$. The first few terms are 1, 7, 41, 239, 1393, ... (Sloane's A002315). The lengths that are one more than the corresponding diagonals are 2, 50, 1682, 57122, ...

The indices giving PRIME NSW numbers are 3, 5, 7, 19, 29, 47, 59, 163, 257, 421, 937, 947, 1493, 1901, ... (Sloane's A005850).

n! Theorem

For any PARTITION μ of n, define a polynomial in $2n$ variables x_1, x_2, ... and y_1, y_2, ... as

$$\Delta_\mu=\det\left|x_i^{p_j}y_i^{q_j}\right|, \tag{1}$$

where (p_j, q_j) are the coordinates of the cells of the partition when it is placed in the coordinate plane with base cell at $(0,0)$ and such that all other coordinates are nonnegative in x and y. Denote the linear span of all derivatives of this polynomial with respect to the variables by $\mathscr{L}[\partial_x\partial_y\Delta_\mu]$, where ∂ represents a PARTIAL DERIVATIVE. This VECTOR SPACE is CLOSED under permutations acting on x_i and y_i simultaneously. Then the n! theorem states that

$$\dim \mathscr{L}[\partial_x\partial_y\Delta_\mu]=n! \tag{2}$$

(Zabrocki). The theorem was proven by M. Haiman in Dec. 1999.

For example, consider the PARTITION $\mu=(2,1)$. Then

$$\Delta_{(2,1)}=\det\begin{vmatrix}1 & 1 & 1\\ x_1 & x_2 & x_3\\ y_1 & y_2 & y_3\end{vmatrix} \tag{3}$$

$$=x_2y_3-x_3y_2-x_1y_3+y_1x_3+x_1y_2-x_2y_1 \tag{4}$$

Then the five derivatives

$$\partial_{x_1}\Delta_{(2,1)}=y_2-y_3 \tag{5}$$

$$\partial_{x_2}\Delta_{(2,1)}=y_3-y_1 \tag{6}$$

$$\partial_{y_1}\Delta_{(2,1)}=x_3-x_2 \tag{7}$$

$$\partial_{y_2}\Delta_{(2,1)}=x_1-x_3 \tag{8}$$

$$\partial_{x_2}\partial_{y_2}\Delta_{(2,1)}=1, \tag{9}$$

together with $\Delta_{(2,1)}$, $3!=6$ elements in all, form a basis for $\mathscr{L}[\partial_x\partial_y\Delta_{(2,1)}]$ (Zabrocki).

HILBERT'S NULLSTELLENSATZ

Number

The word "number" is a general term which refers to a member of a given (possibly ordered) SET. The meaning of "number" is often clear from context (i.e., does it refer to a COMPLEX NUMBER, INTEGER, REAL NUMBER, etc.?). Wherever possible in this work, the word "number" is used to refer to quantities which are INTEGERS, and "CONSTANT" is reserved for nonintegral numbers which have a fixed value. Because terms such as REAL NUMBER, BERNOULLI NUMBER, and IRRATIONAL NUMBER are commonly used to refer to nonintegral quantities, however, it is not possible to be entirely consistent in nomenclature.

To indicate a particular numerical label, the abbreviation "no." is sometimes used (deriving from "numero," the ablative case of the Latin "numerus"), as is the less common "nr."

Number Axis

REAL LINE

Number Field

If r is an ALGEBRAIC NUMBER of degree n, then the totality of all expressions that can be constructed from r by repeated additions, subtractions, multiplications, and divisions is called a number field (or an ALGEBRAIC NUMBER FIELD) generated by r, and is denoted $F[r]$. Formally, a number field is a finite extension $\mathbb{Q}(\alpha)$ of the FIELD $\mathbb{Q}$ of RATIONAL NUMBERS.

The elements of a number field which are ROOTS of a POLYNOMIAL

$$z^n + a_{n-1}z^{n-1} + \cdots + a_0 = 0$$

with integer coefficients and leading coefficient 1 are called the ALGEBRAIC INTEGERS of that field.

Number Field Sieve

An extremely fast factorization method developed by Pollard which was used to factor the RSA-130 NUMBER. This method is the most powerful known for factoring general numbers, and has complexity

$$\mathcal{O}\left\{\exp\left[c(\log n)^{1/3}(\log\log n)^{2/3}\right]\right\}, \tag{1}$$

reducing the *exponent* over the CONTINUED FRACTION FACTORIZATION ALGORITHM and QUADRATIC SIEVE. There are three values of c relevant to different flavors of the method (Pomerance 1996). For the "special" case of the algorithm applied to numbers near a large POWER,

$$c = \left(\tfrac{32}{9}\right)^{1/3} = 1.526285\ldots, \tag{2}$$

for the "general" case applicable to any ODD POSITIVE number which is not a POWER,

$$c = \left(\tfrac{64}{9}\right)^{1/3} = 1.922999\ldots, \tag{3}$$

and for a version using many POLYNOMIALS (Coppersmith 1993),

$$c = \tfrac{1}{3}\left(92 + 26\sqrt{13}\right)^{1/3} = 1.901883\ldots \tag{4}$$

Number Group

FIELD

Number Guessing

By asking a small number of innocent-sounding questions about an unknown number, it is possible to reconstruct the number with absolute certainty (assuming that the questions are answered correctly). Ball and Coxeter (1987) give a number of sets of questions which can be used.

One of the simplest algorithms uses only three queries that can be used to determine an unknown number n from an audience member.

1. Ask the person to compute $n' = 3n$ (i.e., three times the secret number n) and announce if the result is EVEN or ODD.
2. If you were told that n' is EVEN, ask the person to reveal the number n'' which is half of n'. If you were told that n' is ODD, ask the person to reveal the number n'' which is half of $n'+1$.
3. Ask the person to reveal the number of times k which 9 divides evenly into $n''' = 3n''$.

The original number n is then given by $2k$ if n' was EVEN, or $2k+1$ if n' was ODD. For $n = 2m$ even, $n' = 6m$, $n'' = 3m$, $n''' = 9m$, $k = m$, so $2k = 2m = n$. For $n = 2m+1$ odd, $n' = 6m+3$, $n'' = 3m+2$, $n''' = 9m+6$, $k = m$, so $2k+1 = 2m+1 = n$.

Another method asks:

1. Multiply the number n by 5.
2. Add 6 to the product.
3. Multiply the sum by 4.
4. Add 9 to the product.
5. Multiply the sum by 5 and reveal the result n'.

The original number is then given by $n = (n' - 165)/100$, since the above steps give $n' = 5(4(5n+6)+9) = 100n + 165$.

Number Pattern

It is possible to construct simple functions which produce growing patterns. For example, the BAXTER-HICKERSON FUNCTION

$$f(n) = \tfrac{1}{3}(2 \cdot 10^{5n} - 10^{4n} + 2 \cdot 10^{3n} + 10^{2n} + 10^n + 1)$$

produces the sequence 64037, 6634003367, 666334000333667, ...

See also BAXTER-HICKERSON FUNCTION, NUMBER PYRAMID

Number Picking

Place $2n$ balls in a bag and number them 1 to $2n$, then pick half of them at random. The number of different possible sums for $n = 1, 2, 3, \ldots$ are then 2, 5, 10, 17, 26, ... (Sloane's A002522), or $n^2 + 1$

Number Theoretic Transform

Simplemindedly, a number theoretic transform is a generalization of a FAST FOURIER TRANSFORM obtained by replacing $e^{-2\pi ik/N}$ with an nth PRIMITIVE ROOT OF UNITY. This effectively means doing a transform over the QUOTIENT RING $\mathbb{Z}/p\mathbb{Z}$ instead of the COMPLEX NUMBERS $\mathbb{C}$. The theory is rather elegant and uses the language of FINITE FIELDS and NUMBER THEORY.

Number Theory

A vast and fascinating field of mathematics, sometimes called "higher arithmetic," consisting of the study of the properties of whole numbers. PRIMES and PRIME FACTORIZATION are especially important in number theory, as are a number of functions such as the DIVISOR FUNCTION, RIEMANN ZETA FUNCTION, and TOTIENT FUNCTION. Excellent introductions to number theory may be found in Ore (1988) and Beiler (1966). The classic history on the subject (now slightly dated) is that of Dickson (1952).

The great difficulty required to prove relatively simple results in number theory prompted no less an authority than Gauss to remark that "it is just this which gives the higher arithmetic that magical charm which has made it the favorite science of the greatest mathematicians, not to mention its inexhaustible wealth, wherein it so greatly surpasses other parts of mathematics." Gauss, often known as the "prince of mathematics," called mathematics the "queen of the sciences,'" and considered number theory the "queen of mathematics" (Beiler 1966, Goldman 1997).

QUOTIENT-DIFFERENCE TABLE

Numerator

The number p in a FRACTION p/q.

See also DENOMINATOR, FRACTION, RATIONAL NUMBER

Numeric Function

A FUNCTION $f: A \to B$ such that B is a SET of numbers.

Numerical Derivative

While it is usually much easier to compute a DERIVATIVE instead of an INTEGRAL (which is a little strange, considering that "more" functions have integrals than derivatives), there are still many applications where derivatives need to be computed numerically. The simplest approach simply uses the definition of the DERIVATIVE

$$f'(x) \equiv \lim_{h \to 0} \frac{f(x+h) - f(x)}{h}$$

for some small numerical value of $h \ll 1$.

Numerical Integration

The approximate computation of an INTEGRAL using numerical techniques. The numerical computation of an INTEGRAL is sometimes called QUADRATURE. Ueberhuber (1997, p. 71) uses the word "QUADRATURE" to mean numerical computation of a univariate INTEGRAL, and "CUBATURE" to mean numerical computation of a MULTIPLE INTEGRAL.

There are a wide range of methods available for numerical integration. A good source for such techniques is Press *et al.* (1992).

The most straightforward numerical integration technique uses the NEWTON-COTES FORMULAS (also called QUADRATURE FORMULAS), which approximate a function tabulated at a sequence of regularly spaced INTERVALS by various degree POLYNOMIALS. If the endpoints are tabulated, then the 2- and 3-point formulas are called the TRAPEZOIDAL RULE and SIMPSON'S RULE, respectively. The 5-point formula is called BODE'S RULE. A generalization of the TRAPEZOIDAL RULE is ROMBERG INTEGRATION, which can yield accurate results for many fewer function evaluations.

If the functions are known analytically instead of being tabulated at equally spaced intervals, the best numerical method of integration is called GAUSSIAN QUADRATURE. By picking the abscissas at which to evaluate the function, Gaussianquadrature produces the most accurate approximations possible. However, given the speed of modern computers, the additional complication of the GAUSSIAN QUADRATURE formalism often makes it less desirable than simply brute-force calculating twice as many points on a regular grid (which also permits the already computed values of the function to be re-used). An excellent reference for GAUSSIAN QUADRATURE is Hildebrand (1956).

NURBS Curve

A nonuniform rational B-SPLINE curve defined by

$$\mathbf{C}(t) = \frac{\sum_{i=0}^{n} N_{i,p}(t) w_i \mathbf{P}_i}{\sum_{i=0}^{n} N_{i,p}(t) w_i},$$

where p is the order, $N_{i,p}$ are the B-SPLINE basis functions, $\mathbf{P}_i$ are control points, and the weight w_i of $\mathbf{P}_i$ is the last ordinate of the homogeneous point $\mathbf{P}_i^w$. These curves are CLOSED under perspective transformations and can represent CONIC SECTIONS exactly.

Nyquist Frequency

In order to recover all FOURIER components of a periodic waveform, it is necessary to sample more than twice as fast as the *highest* waveform frequency ν, i.e.,

$$f_{\text{Nyquist}} = 2\nu.$$

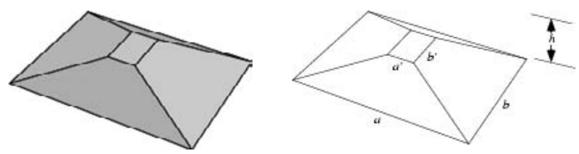
This cutoff frequency f_{Nyquist} above which a signal must be sampled in order to be able to fully reconstruct it is called the Nyquist frequency.

See also FOURIER SERIES, FOURIER TRANSFORM, NYQUIST SAMPLING, OVERSAMPLING, SAMPLING THEOREM

Nyquist Sampling

Sampling at the NYQUIST FREQUENCY.

See also SAMPLING THEOREM



O

O

The symbol $\mathbb{O}$ is sometimes used to represent CAYLEY NUMBERS (also commonly known as octonions).

See also CAYLEY NUMBER

Obelisk

A polyhedron formed by two parallel rectangles, not congruent to each other, whose side faces are trapezoids. The VOLUME is given by

$$\begin{aligned} V &= \tfrac{1}{6}\, h[(2a + a')b + (2a' + a)b'] \\ &= \tfrac{1}{6}\, h[(ab + (a + a')(b + b') + a'b']. \end{aligned}$$

The distance from the bottom base to the CENTROID is

$$\bar{z} = \frac{h(ab + ab' + a'b + 3a'b')}{2(ab + ab' + a'b + 2a'b')}.$$

The term obelisk is sometimes also used to refer to the DAGGER symbol (Bringhurst 1997, p. 275).

See also DAGGER

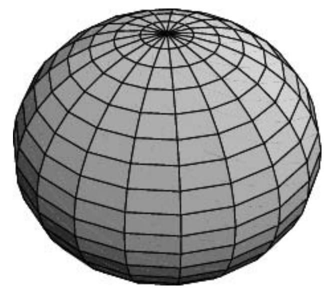
Object



A mathematical structure (e.g., a GROUP, VECTOR SPACE, or DIFFERENTIABLE MANIFOLD) in a CATEGORY.

See also MORPHISM

Oblate Ellipsoid

OBLATE SPHEROID

Oblate Spheroid

A "squashed" SPHEROID for which the equatorial radius a is greater than the polar radius c, so $a > c$ (called an oblate ellipsoid by Tietze 1965, p. 27). An oblate spheroid is a SURFACE OF REVOLUTION obtained by rotating an ELLIPSE about its minor axis (Hilbert and Cohn-Vossen 1999, p. 10). To first approximation, the shape assumed by a rotating fluid (including the Earth, which is "fluid" over astronomical time scales) is an oblate spheroid. The oblate spheroid can be specified parametrically by the usual SPHEROID equations (for a SPHEROID with z-AXIS as the symmetry axis),

$$x = a \sin v \cos u \tag{1}$$

$$y = a \sin v \sin u \tag{2}$$

$$z = c \cos v, \tag{3}$$

with $a > c$, $u \in [0, 2\pi)$, and $v \in [0, \pi]$. Its Cartesian equation is

$$\frac{x^2 + y^2}{a^2} + \frac{z^2}{c^2} = 1. \tag{4}$$

The ELLIPTICITY of an oblate spheroid is defined by

$$e \equiv \sqrt{1 - \frac{c^2}{a^2}}, \tag{5}$$

so that

$$1 - e^2 = \frac{c^2}{a^2}. \tag{6}$$

The radial distance from center of the spheroid as a function of latitude δ is given by

$$r(\delta) = \sqrt{\frac{a^2 + c^2 + (a - c)(a + c)\cos(2\delta)}{2}} \tag{7}$$

$$= a\sqrt{1-e^2\sin^2\delta}. \quad (8)$$

The SURFACE AREA of an oblate spheroid can be computed as a SURFACE OF REVOLUTION about the z-AXIS,

$$S = 2\pi \int r(z)\sqrt{1+[r'(z)]^2}\,dz \quad (9)$$

with radius as a function of z given by

$$r(z) = a\sqrt{1-\left(\frac{z}{c}\right)^2}. \quad (10)$$

Therefore

$$S = 2\pi a \int_{-c}^{c} \sqrt{\left(1-\frac{z^2}{c^2}\right)\left[1+\frac{a^2z^2}{c^2(c^2-z^2)}\right]}\,dz$$

$$= \frac{\pi}{\sqrt{a^2-c^2}} \times \left[2a^2\sqrt{a^2-c^2}+c^2a\ln\left(\frac{a+\sqrt{a^2-c^2}}{a-\sqrt{a^2-c^2}}\right)\right]. \quad (11)$$

Using the identity

$$\sqrt{a^2-c^2} = ae \quad (12)$$

gives

$$S = 2\pi a^2 + \pi\frac{c^2}{e}\ln\left(\frac{1+e}{1-e}\right) \quad (13)$$

(Beyer 1987, p. 131). Note that this is the conventional form in which the surface area of an oblate spheroid is written, although it is formally equivalent to the conventional form for the PROLATE SPHEROID via the identity

$$\frac{c^2\pi}{e(a,\,c)}\ln\left[\frac{1+e(a,\,c)}{1-e(a,\,c)}\right] = \frac{2\pi ac}{e(c,\,a)}\sin^{-1}[e(c,\,a)], \quad (14)$$

where $e(x,\,y)$ is defined by

$$e(x,\,y) \equiv \sqrt{1-\frac{x^2}{y^2}}. \quad (15)$$

The VOLUME of an oblate spheroid can be computed from the formula for a general ELLIPSOID with $b=a$,

$$V = \tfrac{4}{3}\pi a^2 c \quad (16)$$

(Beyer 1987, p. 131).

An oblate spheroid with its origin at a FOCUS has equation

$$r = \frac{a(1-e^2)}{1+e\cos\phi}. \quad (17)$$

Define k and expand up to POWERS of e^6,

$$k \equiv e^2(1-e^2)^{-1} = e^2(1+e^2-2e^4+6e^6+\ldots)$$

$$= e^2+e^4-2e^6+\ldots \quad (18)$$

$$k^2 = e^4+e^6+\ldots \quad (19)$$

$$k^3 = e^6+\ldots \quad (20)$$

Expanding r in POWERS of ELLIPTICITY to e^6 therefore yields

$$\frac{r}{a} = 1-\tfrac{1}{2}(e^2+e^4-2e^4+6e^6)\sin^2\delta+\tfrac{3}{4}(e^4+e^6)\sin^4\delta - \tfrac{15}{8}e^6\sin^6\delta+\ldots. \quad (21)$$

In terms of LEGENDRE POLYNOMIALS,

$$\frac{r}{a} = \left(1-\tfrac{1}{6}e^2-\tfrac{11}{20}e^4-\tfrac{103}{1680}e^6\right) +\left(-\tfrac{1}{3}e^2-\tfrac{5}{42}e^4-\tfrac{3}{56}e^6\right)P_2 +\left(\tfrac{3}{35}e^4+\tfrac{57}{770}e^6\right)P_4-\tfrac{5}{231}e^6P_6+\ldots. \quad (22)$$

The ELLIPTICITY may also be expressed in terms of the OBLATENESS (also called FLATTENING), denoted ϵ or f.

$$\epsilon \equiv \frac{a-c}{a} \quad (23)$$

$$c = a(1-\epsilon) \quad (24)$$

$$c^2 = a^2(1-\epsilon)^2 \quad (25)$$

$$(1-\epsilon)^2 = 1-e^2, \quad (26)$$

so

$$\epsilon = 1-\sqrt{1-e^2} \quad (27)$$

and

$$e^2 = 1-(1-\epsilon)^2 = 1-(1-2\epsilon+\epsilon^2) = 2\epsilon-\epsilon^2 \quad (28)$$

$$r = a\left[1+\frac{2\epsilon-\epsilon^2}{(1-\epsilon)^2}\sin^2\delta\right]^{-1/2}. \quad (29)$$

Define k and expand up to POWERS of ϵ^6

$$k \equiv (2\epsilon-\epsilon)(1-\epsilon)^{-2} = (2\epsilon-\epsilon^2)(1+2\epsilon-6\epsilon^2+\ldots)$$

$$= 2\epsilon+4\epsilon^4-12\epsilon^3-\epsilon^2-2\epsilon^3+\ldots$$

$$= 2\epsilon+3\epsilon^2-14\epsilon^3+\ldots \quad (30)$$

$$k^2 = 4\epsilon^2+6\epsilon^3+\ldots \quad (31)$$

$$k^3 = 8\epsilon^3+\ldots \quad (32)$$

Expanding r in POWERS of the OBLATENESS to ϵ^3 yields

$$\frac{r}{a} = 1 - \tfrac{1}{2}(2\epsilon + 3\epsilon^2 - 14\epsilon^3)\sin^2\delta + \tfrac{3}{4}(4\epsilon^2 + 6\epsilon^3)\sin^4\delta + 8\epsilon^3\sin^6\delta + \ldots. \tag{33}$$

In terms of LEGENDRE POLYNOMIALS,

$$\frac{r}{a} = \left(1 - \tfrac{1}{3}\epsilon - \tfrac{2}{5}\epsilon^2 - \tfrac{13}{105}\epsilon^3\right) + \left(-\tfrac{2}{3}\epsilon - \tfrac{1}{7}\epsilon^2 - \tfrac{1}{21}\epsilon^3\right)P_2 + \left(\tfrac{12}{35}\epsilon^2 - \tfrac{96}{385}\epsilon^3\right)P_4 - \tfrac{40}{231}\epsilon^3 P_6 + \ldots. \tag{34}$$

To find the projection of an oblate spheroid onto a PLANE, set up a coordinate system such that the z-AXIS is towards the observer, and the x-AXIS is in the PLANE of the page. The equation for an oblate spheroid is

$$r(\theta) = a\left[1 + \frac{2\epsilon - \epsilon^2}{(1-\epsilon)^2}\cos^2\theta\right]^{-1/2}. \tag{35}$$

Define

$$k \equiv \frac{2\epsilon - \epsilon^2}{(1-\epsilon)^2}, \tag{36}$$

and $x \equiv \sin\theta$. Then

$$r(\theta) = a[1 + k(1-x^2)]^{-1/2} = a(1 + k - kx^2)^{-1/2}. \tag{37}$$

Now rotate that spheroid about the x-AXIS by an ANGLE B so that the new symmetry axes for the spheroid are $x' \equiv x$, y', and z'. The projected height of a point in the $x = 0$ PLANE on the y-AXIS is

$$y = r(\theta)\cos(\theta - B) = r(\theta)(\cos\theta\cos B - \sin\theta\sin B) = r(\theta)\left(\sqrt{1-x^2}\cos B + x\sin B\right). \tag{38}$$

To find the highest projected point,

$$\frac{dy}{d\theta} = \frac{a\sin(B-\theta)}{(1 + k\cos^2\theta)^{1/2}} + ak\frac{\cos(B-\theta)\cos\theta\sin\theta}{(1 + k\cos^2\theta)^{3/2}} = 0. \tag{39}$$

Simplifying,

$$\tan(B-\theta)(1 + k\cos^2\theta) + k\cos\theta\sin\theta = 0. \tag{40}$$

But

$$\tan(B-\theta) = \frac{\tan B - \tan\theta}{1 + \tan B\tan\theta} = \frac{\tan B - \dfrac{\sin\theta}{\sqrt{1-\sin^2\theta}}}{1 + \tan B\dfrac{\sin\theta}{\sqrt{1-\sin^2\theta}}} = \frac{\sqrt{1-\sin^2\theta}\tan B - \sin\theta}{\sqrt{1-\sin^2\theta} + \tan B\sin\theta} \tag{41}$$

Plugging (41) into (40),

$$\frac{\sqrt{1-x^2}\tan B - x}{\sqrt{1-x^2} + x\tan B}[1 + k(1-x^2)] + kx\sqrt{1-x^2} = 0 \tag{42}$$

and performing a number of algebraic simplifications

$$\left(\sqrt{1-x^2}\tan B - x\right)(1 + k - kx^2) + kx\sqrt{1-x^2} \times \left(\sqrt{1-x^2} + x\tan B\right) = 0 \tag{43}$$

$$\left[(1+k)\sqrt{1-x^2}\tan B - kx^2\sqrt{1-x^2}\tan B - x - kx + kx^3\right] + \left[kx(1-x^2) + kx^2\sqrt{1-x^2}\tan B\right] \tag{44}$$

$$(1+k)\tan B\sqrt{1-x^2} - kx(1-x^2) - x + kx(1-x^2) = 0 \tag{45}$$

$$(1+k)\tan B\sqrt{1-x^2} = x \tag{46}$$

$$(1+k)^2\tan^2 B(1-x^2) = x^2 \tag{47}$$

$$x^2\left[1 + (1+k)^2\tan^2 B\right] = (1+k)^2\tan^2 B \tag{48}$$

finally gives the expression for x in terms of B and k,

$$x^2 = \frac{\tan^2 B(1+k)^2}{1 + (1+k)^2\tan^2 B}. \tag{49}$$

Combine (37) and (38) and plug in for x,

$$y = a\frac{\sqrt{1-x^2}\cos B + x\sin B}{\sqrt{1 + k - kx^2}} = a\frac{\cos B + (1+k)\dfrac{\sin^2 B}{\cos B}}{\sqrt{(1+k)[1 + (1+k)\tan^2 B]}} = a\frac{\cos^2 B + (1+k)\sin^2 B}{\cos B\sqrt{(1+k)[1 + (1+k)\tan^2 B]}}. \tag{50}$$

Now re-express k in terms of a and c, using $\epsilon \equiv 1 - c/a$,

$$k \equiv \frac{(2-\epsilon)\epsilon}{(1-\epsilon)^2} = \frac{\left(1 + \dfrac{c}{a}\right)\left(1 - \dfrac{c}{a}\right)}{\left(\dfrac{c}{a}\right)^2} = \frac{1 - \left(\dfrac{c}{a}\right)^2}{\left(\dfrac{c}{a}\right)^2} = \left(\frac{a}{c}\right)^2 - 1, \tag{51}$$

so

$$1 + k = \left(\frac{a}{c}\right)^2 \tag{52}$$

Plug (51) and (52) into (50) to obtain the SEMIMINOR AXIS of the projected oblate spheroid,

$$c' = a\frac{\cos^2 B + \left(\frac{a}{c}\right)^2 \sin^2 B}{\cos B\sqrt{\left(\frac{a}{c}\right)^2\left[1+\left(\frac{a}{c}\right)^2\tan^2 B\right]}}$$

$$= a\frac{\cos^2 B + \left(\frac{a}{c}\right)^2 \sin^2 B}{\frac{a}{c}\sqrt{\cos^2 B + \left(\frac{a}{c}\right)^2 \sin^2 B}}$$

$$= c\sqrt{\cos^2 B + \left(\frac{a}{c}\right)^2 \sin^2 B} = \sqrt{c^2\cos^2 B + a^2 \sin^2 B}$$

$$= a\sqrt{(1-\epsilon)^2\cos^2 B + \sin^2 B}. \tag{53}$$

We wish to find the equation for a spheroid which has been rotated about the $x \equiv x'$-axis by ANGLE B, then the z-AXIS by ANGLE P

$$\begin{bmatrix} x' \\ y' \\ z' \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos B & \sin B \\ 0 & -\sin B & \cos B \end{bmatrix}\begin{bmatrix} \cos P & 0 & \sin P \\ 0 & 1 & 0 \\ -\sin P & 0 & \cos P \end{bmatrix}\begin{bmatrix} x \\ y \\ z \end{bmatrix}$$

$$= \begin{bmatrix} \cos P & 0 & \sin P \\ -\sin B\sin P & \cos B & \sin B\cos P \\ -\cos B\sin P & -\sin B & \cos B\cos P \end{bmatrix}\begin{bmatrix} x \\ y \\ z \end{bmatrix}. \tag{54}$$

Now, in the original coordinates (x', y', z'), the spheroid is given by the equation

$$\frac{x'^2}{a^2} + \frac{y'^2}{c^2} + \frac{z'^2}{a^2} = 1, \tag{55}$$

which becomes in the new coordinates,

$$\frac{(x\cos P + y\sin P)^2}{a^2} + \frac{(-x\sin B\sin P + z\cos B + y\sin B\cos P)^2}{a^2} + \frac{(-x\cos B\sin P - z\sin B + y\cos B\cos P)^2}{c^2} = 1. \tag{56}$$

Collecting COEFFICIENTS,

$$Ax^2 + By^2 + Cz^2 + Dxy + Exz + Fyz = 1, \tag{57}$$

where

$$A \equiv \frac{\cos^2 P + \sin^2 B\sin^2 P}{a^2} + \frac{\cos^2 B\sin^2 P}{c^2} \tag{58}$$

$$B \equiv \frac{\sin^2 P + \sin^2 B\cos^2 P}{a^2} + \frac{\cos^2 B\cos^2 P}{c^2} \tag{59}$$

$$C \equiv \frac{\cos^2 B}{a^2} + \frac{\sin^2 B}{c^2} \tag{60}$$

$$D \equiv 2\cos P\sin P\left(\frac{1-\sin^2 B}{a^2} - \frac{\cos^2 B}{c^2}\right)$$

$$= 2\cos P\sin P\cos^2 B\left(\frac{1}{a^2} - \frac{1}{c^2}\right) \tag{61}$$

$$E \equiv 2\sin B\cos B\sin P\left(\frac{1}{b^2} - \frac{1}{a^2}\right) \tag{62}$$

$$F \equiv 2\sin B\cos B\cos P\left(\frac{1}{a^2} - \frac{1}{b^2}\right). \tag{63}$$

If we are interested in computing z, the radial distance from the symmetry axis of the spheroid (y) corresponding to a point

$$Cz^2 + (Ex + Fy)z + (Ax^2 + By^2 + Dxy - 1)$$

$$= Cz^2 + G(x,y)z + H(x,y) = 0, \tag{64}$$

where

$$G(x,y) \equiv Ex + Fy \tag{65}$$

$$H(x,y) \equiv Ax^2 + By^2 + Dxy - 1. \tag{66}$$

z can now be computed using the quadratic equation when (x, y) is given,

$$z = \frac{-G(x,y) \pm \sqrt{G^2(x,y) - 4CG(x,y)}}{2C}. \tag{67}$$

If $P = 0$, then we have $\sin P = 0$ and $\cos P = 1$, so (58) to (63) and (65) to (66) become

$$A \equiv \frac{1}{a^2} \tag{68}$$

$$B \equiv \frac{\sin^2 B}{a^2} + \frac{\cos^2 B}{b^2} \tag{69}$$

$$C \equiv \frac{\cos^2 B}{a^2} + \frac{\sin^2 B}{b^2} \tag{70}$$

$$D \equiv 0 \tag{71}$$

$$E \equiv 0 \tag{72}$$

$$F \equiv 2\sin B\cos B\left(\frac{1}{a^2} - \frac{1}{b^2}\right) \tag{73}$$

$$G(x,y) \equiv Fy = 2y\sin B\cos B\left(\frac{1}{a^2} - \frac{1}{b^2}\right) \tag{74}$$

$$H(x,y) \equiv Ax^2 + By^2 - 1$$
$$= \frac{x^2}{a^2} + y^2\left(\frac{\sin^2 B}{a^2} + \frac{\cos^2 B}{b^2}\right) - 1. \quad (75)$$

Oblate Spheroid Geodesic

The GEODESIC on an OBLATE SPHEROID can be computed analytically, although the resulting expression is much more unwieldy than for a simple SPHERE. A spheroid with equatorial radius a and polar radius c can be specified parametrically by

$$x = a \sin v \cos u \quad (1)$$
$$y = a \sin v \sin u \quad (2)$$
$$z = c \cos v, \quad (3)$$

where $a > c$. Using the first PARTIAL DERIVATIVES

$$\frac{\partial x}{\partial u} = -a \sin v \sin u \qquad \frac{\partial x}{\partial v} = a \cos v \cos u \quad (4)$$
$$\frac{\partial y}{\partial u} = a \sin v \cos u \qquad \frac{\partial y}{\partial v} = a \cos v \sin u \quad (5)$$
$$\frac{\partial z}{\partial u} = 0 \qquad \frac{\partial z}{\partial v} = -c \sin v, \quad (6)$$

and second PARTIAL DERIVATIVES

$$\frac{\partial^2 x}{\partial u^2} = -a \sin v \cos u \qquad \frac{\partial^2 x}{\partial v^2} = -a \sin v \cos u \quad (7)$$
$$\frac{\partial^2 y}{\partial u^2} = -a \sin v \sin u \qquad \frac{\partial^2 y}{\partial v^2} = -a \sin v \sin u \quad (8)$$
$$\frac{\partial^2 z}{\partial u^2} = 0 \qquad \frac{\partial^2 z}{\partial v^2} = -z \cos v, \quad (9)$$

gives the GEODESICS functions as

$$P \equiv \left(\frac{\partial x}{\partial u}\right)^2 + \left(\frac{\partial y}{\partial u}\right)^2 + \left(\frac{\partial z}{\partial u}\right)^2$$
$$= a^2(\sin^2 v \cos^2 u + \sin^2 v \sin^2 u)$$
$$= a^2 \sin^2 v \quad (10)$$

$$Q \equiv \frac{\partial x}{\partial u}\frac{\partial x}{\partial v} + \frac{\partial y}{\partial u}\frac{\partial y}{\partial v} + \frac{\partial z}{\partial u}\frac{\partial z}{\partial v} = 0 \quad (11)$$

$$R \equiv \left(\frac{\partial x}{\partial v}\right)^2 + \left(\frac{\partial y}{\partial v}\right)^2 + \left(\frac{\partial z}{\partial v}\right)^2$$
$$= a^2 + (c^2 - a^2)\sin^2 v = a^2(1 - e^2 \sin^2 v), \quad (12)$$

where

$$e = \sqrt{\frac{a^2 - c^2}{a^2}} \quad (13)$$

is the ELLIPTICITY.

Since $Q = 0$ and P and R are explicit functions of v only, we can use the special form of the GEODESIC equation

$$u = \int \sqrt{\frac{R}{P^2 - c_1^2 P}}\,dv = \int \sqrt{\frac{a^2(1 - e^2 \sin^2 v)}{a^4 \sin^4 v - c_1^2 a^2 \sin^2 v}}\,dv$$
$$= \frac{1}{c_1}\int \sqrt{\frac{1 - e^2 \sin^2 v}{\left(\frac{a}{c_1}\right)^2 \sin^2 v - 1}}\,\frac{dv}{\sin v}. \quad (14)$$

Integrating gives

$$u = -\frac{e^2 F\left(\phi \left| \frac{(d^2-1)e^2}{d^2-e^2}\right.\right) - d^2 \Pi\left(d^2 - 1,\ \phi\left|\frac{(d^2-1)e^2}{d^2-e^2}\right.\right)}{c_1 \sqrt{d^2 - e^2}}, \quad (15)$$

where

$$d \equiv \frac{a}{c_1} \quad (16)$$

$$\cos\phi \equiv \frac{d \cos v}{\sqrt{d^2 - 1}}, \quad (17)$$

$F(\phi|m)$ is an ELLIPTIC INTEGRAL OF THE FIRST KIND with PARAMETER m, and $\Pi(\phi|m, k)$ is an ELLIPTIC INTEGRAL OF THE THIRD KIND.

GEODESICS other than MERIDIANS of an OBLATE SPHEROID undulate between two parallels with latitudes equidistant from the equator. Using the WEIERSTRASS SIGMA FUNCTION and WEIERSTRASS ZETA FUNCTION, the GEODESIC on the OBLATE SPHEROID can be written as

$$x + iy = \kappa\,\frac{\sigma(a + u)}{\sigma(u)\sigma(a)}\,e^{u[\eta - \zeta(\omega + a)]} \quad (18)$$

$$x - iy = \kappa\,\frac{\sigma(a - u)}{\sigma(u)\sigma(a)}\,e^{-u[\eta - \zeta(\omega + a)]} \quad (19)$$

$$z^2 = \lambda^2 \frac{\sigma(\omega'' + u)(\omega'' - u)}{\sigma^2(u)\sigma^2(a)} \quad (20)$$

(Forsyth 1960, pp. 108–109; Halphen 1886–1891).

The equation of the GEODESIC can be put in the form

$$d\phi = \frac{\sqrt{1 - e^2 \sin^2 v} \sin a}{\sqrt{\sin^2 v - \sin^2 a} \sin v} dv, \quad (21)$$

where a is the smallest value of v on the curve. Furthermore, the difference in longitude between points of highest and next lowest latitude on the curve is

$$\pi - 2 \frac{\sqrt{1 - e^2 \sin^2 a}}{\sin a} \int_0^{\kappa} \frac{\operatorname{dn} u - \operatorname{dn}^2 u}{1 + \cot^2 a \operatorname{sn}^2 u} du, \quad (22)$$

where the MODULUS of the ELLIPTIC FUNCTION is

$$k = \frac{e \cos a}{\sqrt{1 - e^2 \sin^2 a}} \quad (23)$$

(Forsyth 1960, p. 446).

Oblate Spheroidal Coordinates

A system of CURVILINEAR COORDINATES in which two sets of coordinate surfaces are obtained by revolving the curves of the ELLIPTIC CYLINDRICAL COORDINATES about the Y-AXIS which is relabeled the Z-AXIS. The third set of coordinates consists of planes passing through this axis.

$$x = a \cosh \xi \cos \eta \cos \phi \quad (1)$$

$$y = a \cosh \xi \cos \eta \sin \phi \quad (2)$$

$$z = a \sinh \xi \sin \eta, \quad (3)$$

where $\xi \in [0, \infty)$, $\eta \in [-\pi/2, \pi/2]$, and $\phi \in [0, 2\pi)$. Arfken (1970) uses (u, v, φ) instead of (ξ, η, ϕ). The SCALE FACTORS are

$$h_\xi = a \sqrt{\sinh^2 \xi + \sin^2 \eta} \quad (4)$$

$$h_\eta = a \sqrt{\sinh^2 \xi + \sin^2 \eta} \quad (5)$$

$$h_\phi = a \cosh \xi \cos \eta. \quad (6)$$

The LAPLACIAN is

$$\nabla^2 f = \frac{1}{a^3(\sinh^2 \xi + \sinh^2 \eta)\cosh \xi \cos \eta} \times \left[\frac{\partial f}{\partial \xi}\left(a \cosh \xi \cos \eta \frac{\partial f}{\partial \eta}\right) + \frac{\partial f}{\partial \eta}\left(a \cosh \xi \cos \eta \frac{\partial f}{\partial \eta}\right) + \frac{a^2(\sinh^2 \xi + \sinh^2 \eta)}{a \cosh \xi \cos \eta} \frac{\partial^2 f}{\partial \phi^2}\right]$$

$$= \frac{1}{a^3(\sinh^2 \xi + \sinh^2 \eta)\cosh \xi \cos \eta} \times \left[a \sinh \xi \cos \eta \frac{\partial f}{\partial \xi} + a \cosh \xi \cos \eta \frac{\partial^2 f}{\partial \xi^2} + a \sinh \xi \cos \eta \frac{\partial f}{\partial \eta} + a \cosh \xi \cos \eta \frac{\partial^2 f}{\partial \eta^2}\right]$$

$$+ \frac{1}{a^2(\sinh^2 \xi + \sinh^2 \eta)} \frac{\partial^2 f}{\partial \phi^2} = \frac{1}{a^2(\sinh^2 \xi + \sinh^2 \eta)} \times \left[\frac{1}{\cosh \xi} \frac{\partial}{\partial \xi}\left(\cosh \xi \frac{\partial f}{\partial \xi}\right) + \frac{1}{\cosh \eta} \frac{\partial}{\partial \eta}\left(\cosh \eta \frac{\partial f}{\partial \eta}\right)\right] + \frac{1}{a^2(\cosh^2 \xi + \cos^2 \eta)} \frac{\partial^2 f}{\partial \phi^2} \quad (7)$$

$$= \frac{1}{\sinh^2 \eta + \sinh^2 \xi} \times \left[(\operatorname{sech}^2 \xi \tan^2 \eta + \sec^2 \tanh^2 \xi) \frac{\partial^2}{\partial \phi^2} + \tanh \xi \frac{\partial}{\partial \xi} + \frac{\partial^2}{\partial \xi^2} - \tan \eta \frac{\partial}{\eta} + \frac{\partial^2}{\eta^2}\right]. \quad (8)$$

An alternate form useful for "two-center" problems is defined by

$$\xi_1 = \sinh \xi \quad (9)$$

$$\xi_1' = \cosh \xi \quad (10)$$

$$\xi_2 = \cos \eta \quad (11)$$

$$\xi_3 = \phi, \quad (12)$$

where $\xi_1 \in [1, \infty]$, $\xi_2 \in [-1, 1]$, and $\xi_3 \in [0, 2\pi)$. In

these coordinates,

$$y = a\xi_1'\xi_2 \sin \xi_3 \tag{13}$$

$$z = a\sqrt{(\xi_1'^2 - 1)(1 - \xi_2^2)} \tag{14}$$

$$x = a\xi_1'\xi_2 \cos \xi_3 \tag{15}$$

(Abramowitz and Stegun 1972). The SCALE FACTORS are

$$h_{\xi_1} = a\sqrt{\frac{\xi_1^2 - \xi_2^2}{\xi_1^2 - 1}} \tag{16}$$

$$h_{\xi_2} = a\sqrt{\frac{\xi_1^2 - \xi_2^2}{1 - \xi_2^2}} \tag{17}$$

$$h_{\xi_3} = a\xi\eta, \tag{18}$$

and the LAPLACIAN is

$$\nabla^2 f = \frac{1}{a^2}\left\{\frac{1}{\xi_1^2 + \xi_2^2}\frac{\partial}{\partial \xi_1}\left[(\xi_1^2 + 1)\frac{\partial f}{\partial \xi_1}\right] + \frac{1}{\xi_1^2 + \xi_2^2}\frac{\partial}{\partial \xi_2}\left[(1 - \xi_2^2)\frac{\partial f}{\partial \xi_2}\right] + \frac{1}{(\xi_1^2 - 1)(1 - \xi_2^2)}\frac{\partial^2 f}{\partial \xi_3^2}\right\}. \tag{19}$$

The HELMHOLTZ DIFFERENTIAL EQUATION is separable.

Oblate Spheroidal Wave Function

The wave equation in OBLATE SPHEROIDAL COORDINATES is

$$\nabla^2\Phi + k^2\Phi = \frac{\partial}{\partial \xi_1}\left[(\xi_1^2 + 1)\frac{\partial \Phi}{\partial \xi_1}\right] + \frac{\partial}{\partial \xi_2}\left[(1 - \xi_2^2)\frac{\partial \Phi}{\partial \xi_2}\right] + \frac{\xi_1^2 + \xi_2^2}{(\xi_1^2 + 1)(1 - x_2^2)}\frac{\partial^2 \Phi}{\partial \phi^2} + c(\xi_1^2 + \xi_2^2)\Phi = 0, \tag{1}$$

where

$$c \equiv \tfrac{1}{2} ak. \tag{2}$$

Substitute in a trial solution

$$\Phi = R_{mn}(c, \xi_1) S_{mn}(c, \xi_2) {}^{\cos}_{\sin}(m\phi). \tag{3}$$

The radial differential equation is

$$\frac{d}{d\xi_2}\left[(1 + \xi_2^2)\frac{d}{d\xi_2} S_{mn}(c, \xi_2)\right] - \left(\lambda_{mn} - c^2\xi_2^2 + \frac{m^2}{1 + \xi_2^2}\right) R_{mn}(c, \xi_2) = 0, \tag{4}$$

and the angular differential equation is

$$\frac{d}{d\xi_2}\left[(1 - \xi_2^2)\frac{d}{d\xi_2} S_{mn}(c, \xi_2)\right] - \left(\lambda_{mn} - c^2\xi_2^2 + \frac{m^2}{1 - \xi_2^2}\right) R_{mn}(c, \xi_2) = 0 \tag{5}$$

(Abramowitz and Stegun 1972, pp. 753–755; Zwillinger 1997, p. 127).

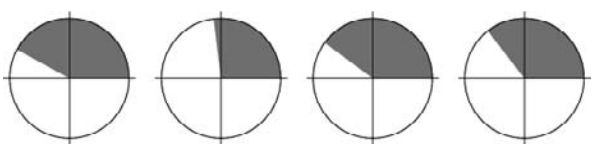
Obstruction



Obstruction theory studies the extensibility of maps using algebraic gadgets. While the terminology rapidly becomes technical and convoluted (as Iyanaga and Kawada note, "It is extremely difficult to discuss higher obstructions in general since they involve many complexities"), the ideas associated with obstructions are very important in modern algebraic topology.

See also Algebraic Topology, Chern Class, Eilenberg-Mac Lane Space, Stiefel-Whitney Class

Obtuse Angle

An angle greater than $\pi/2$ radians (90°) and less than π radians (180°).

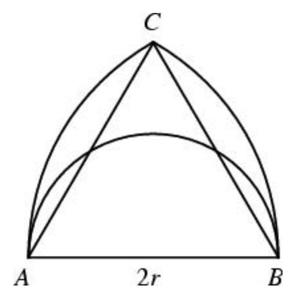
See also Acute Angle, Full Angle, Obtuse Triangle, Reflex Angle, Right Angle, Straight Angle

Obtuse Triangle

An obtuse triangle is a triangle in which one of the angles is an obtuse angle. (Obviously, only a single angle in a triangle can be obtuse or it wouldn't be a triangle.) A triangle must be either obtuse, acute, or right.

From the law of cosines, for a triangle with side lengths a, b, and c,

$$\cos C = \frac{a^2 + b^2 - c^2}{2ab},$$



with C the angle opposite side C. For an angle to be obtuse, $\cos C < 0$. Therefore, an obtuse triangle satisfies one of $a^2 + b^2 < c^2$, $b^2 + c^2 < a^2$, or $c^2 + a^2 < b^2$.

An obtuse triangle can be dissected into no fewer than seven acute triangles (Wells 1986, p. 71).

A famous problem is to find the chance that three points picked randomly in a plane are the vertices of an obtuse triangle (Eisenberg and Sullivan 1996). Unfortunately, the solution of the problem depends on the procedure used to pick the "random" points (Portnoy 1994). In fact, it is impossible to pick random variables which are uniformly distributed in the plane (Eisenberg and Sullivan 1996). Guy (1993) gives a variety of solutions to the problem. Woolhouse (1886) solved the problem by picking uniformly distributed points in the unit disk, and obtained

$$P_2 = 1 - \left(\frac{4}{\pi^2} - \frac{1}{8}\right) = \frac{9}{8} - \frac{4}{\pi^2} = 0.719715\ldots. \quad (1)$$

The problem was generalized by Hall (1982) to n-D ball triangle picking, and Buchta (1986) gave closed form evaluations for Hall's integrals.

Lewis Carroll (1893) posed and gave another solution to the problem as follows. Call the longest side of a triangle AB, and call the diameter $2r$. Draw arcs from A and B of radius $2r$. Because the longest side of the triangle is defined to be AB, the third vertex of the triangle must lie within the region $ABCA$. If the third vertex lies within the semicircle, the triangle is an obtuse triangle. If the vertex lies *on* the semicircle (which will happen with probability 0), the triangle is a right triangle. Otherwise, it is an acute triangle. The chance of obtaining an obtuse triangle is then the ratio of the area of the semicircle to that of $ABCA$. The area of $ABCA$ is then twice the area of a sector minus the area of the triangle.

$$A_{\text{whole figure}} = 2\left(\frac{4\pi r^2}{6}\right) - \sqrt{3}r^2 = r^2\left(\tfrac{4}{3}\pi - \sqrt{3}\right). \quad (2)$$

Therefore,

$$P = \frac{\frac{1}{2}\pi r^2}{r^2\left(\frac{4}{3}\pi - \sqrt{3}\right)} = \frac{3\pi}{8\pi - 6\sqrt{3}} = 0.63938\ldots. \quad (3)$$

Ochoa Curve

The elliptic curve

$$3Y^2 = 2X^3 + 386X^2 + 256X - 58195,$$

given in Weierstrass form as

$$y^2 = x^3 - 440067x + 106074110.$$

The complete set of solutions to this equation consists of $(x, y) = (-761, 504)$, $(-745, 4520)$, $(-557, 13356)$, $(-446, 14616)$, $(-17, 10656)$, (91, 8172), (227, 4228), (247, 3528), (271, 2592), (455, 200), (499, 3276), (523, 4356), (530, 4660), (599, 7576), (751, 14112), (1003, 25956), (1862, 75778), (3511, 204552), (5287, 381528), (23527, 3607272), (64507, 16382772), (100102, 31670478), and (1657891, 2134685628) (Stroeker and de Weger 1994).

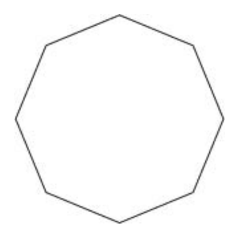
Octacontagon

An 80-sided polygon.



Octadecagon

An 18-sided polygon, sometimes also called an octakaidecagon.

See also Polygon, Regular Polygon, Trigonometry Values Pi/18

Octagon

An octagon is an eight-sided polygon. The inradius r, circumradius R, and area A of the *regular* octagon can be computed directly from the formulas for a general regular polygon with side length s and $n = 8$ sides as

$$r = \tfrac{1}{2} s \cot\left(\frac{\pi}{8}\right) = \tfrac{1}{2}\left(1 + \sqrt{2}\right)s \quad (1)$$

$$R = \tfrac{1}{2}s \csc\left(\frac{\pi}{8}\right) = \tfrac{1}{2}\sqrt{4 + 2\sqrt{2}}s \quad (2)$$

$$A = \tfrac{1}{4}ns^2 \cot\left(\frac{\pi}{8}\right) = 2\left(1 + \sqrt{2}\right)s^2. \quad (3)$$

See also Octahedron, Polygon, Regular Polygon, Trigonometry Values Pi/8

Octagonal Heptagonal Number

A number which is simultaneously octagonal and heptagonal. Let O_m denote the mth octagonal number and H_n the nth heptagonal number, then a number which is both octagonal and hexagonal satisfies the equation $H_n = O_m$, or

$$\tfrac{1}{2}n(5n-3) = m(3m-2). \quad (1)$$

Completing the square and rearranging gives

$$3(10n-3)^2 - 40(3m-1)^2 = -13. \quad (2)$$

Therefore, defining

$$x \equiv (10n-3) \quad (3)$$

$$y \equiv 2(3m-1) \quad (4)$$

gives the second-order Diophantine equation

$$3x^2 - 10y^2 = -13 \quad (5)$$

The first few solutions are $(x, y) = (3, 2)$, (7, 4), (73, 40), (157, 86), ... These give the integer solutions (1, 1), (345, 315), (166145, 151669), ... (Sloane's A048904 and A048905), corresponding to the octagonal heptagonal numbers 1, 297045, 69010153345, ... (Sloane's A048906).

Octagonal Hexagonal Number

A number which is simultaneously octagonal and hexagonal. Let O_n denote the nth octagonal number and H_m the mth hexagonal number, then a number which is both octagonal and hexagonal satisfies the equation $O_n = H_m$, or

$$n(3n-2) = m(2m-1). \quad (1)$$

Completing the square and rearranging gives

$$8(3n-1)^2 - 3(4m-1)^2 = 5. \quad (2)$$

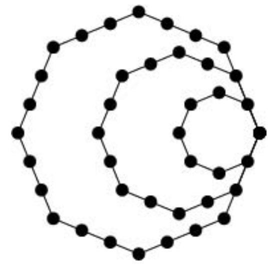
Therefore, defining

$$x \equiv 2(3n-1) \quad (3)$$

$$y \equiv 4m-1 \quad (4)$$

gives the second-order Diophantine equation

$$2x^2 - 3y^2 = 5 \quad (5)$$



The first few solutions are $(x, y) = (2, 1)$, (4, 3), (16, 13), (38, 31), (158, 129), (376, 307), ... These give the solutions $(n, m) = (2/3, 1/2)$, (1, 1), (3, 7/2), (20/3, 8), (80/3, 65/2), (63, 77), ..., of which the integer solutions are (1, 1), (63, 77), (6141, 7521), (601723, 736957), ... (Sloane's A046190 and A046191), corresponding to the octagonal hexagonal numbers 1, 11781, 113123361, 1086210502741, ... (Sloane's A046192).

See also Hexagonal Number, Octagonal Number, Octagonal Pentagonal Number, Octagonal Square Number, Octagonal Triangular Number

Octagonal Number

A polygonal number of the form $n(3n-2)$. The first few are 1, 8, 21, 40, 65, 96, 133, 176, ... (Sloane's A000567). The generating function for the octagonal numbers is

$$\frac{x(5x+1)}{(1-x)^3} = x + 8x^2 + 21x^3 + 40x^4 + \ldots.$$

See also Octagonal Heptagonal Number, Octagonal Hexagonal Number, Octagonal Pentagonal Number, Octagonal Square Number, Octagonal Triangular Number

References

Sloane, N. J. A. Sequences A000567/M4493 in "An On-Line Version of the Encyclopedia of Integer Sequences." http://www.research.att.com/~njas/sequences/eisonline.html.

Octagonal Pentagonal Number

A number which is simultaneously octagonal and pentagonal. Let O_n denote the nth octagonal number and P_m the mth pentagonal number, then a number which is both octagonal and pentagonal satisfies the equation $O_n = P_m$, or

$$n(3n-2) = \tfrac{1}{2}m(3m-1). \quad (1)$$

Completing the square and rearranging gives

$$(6m-1)^2 - 8(3n-1)^2 = -7. \quad (2)$$

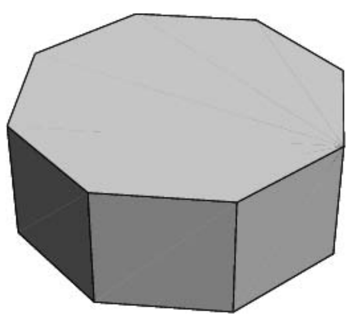
Therefore, defining

$$x \equiv (6m - 1) \quad (3)$$

$$y \equiv 2(3n - 1) \quad (4)$$

gives the PELL EQUATION

$$x^2 - 2y^2 = -7. \quad (5)$$



The first few solutions are $(x, y) = (1, 2)$, $(5, 4)$, $(11, 8)$, $(31, 22)$, $(65, 46)$, ... These give the solutions $(n, m) = (1/3, 2/3)$, $(1, 1)$, $(2, 5/3)$, $(16/3, 4)$, $(11, 8)$, ..., of which the integer solutions are (1, 1), (11, 8), (1025, 725), (12507, 8844), ... (Sloane's A046187 and A046188), corresponding to the octagonal pentagonal numbers 1, 176, 1575425, 234631320, 2098015778145, ... (Sloane's A046189).

Octagonal Prism

A PRISM composed of octagonal faces. The regular right octagonal prism of unit edge length has SURFACE AREA and VOLUME

$$S = 4\left(3 + \sqrt{2}\right)$$

$$V = 2\left(1 + \sqrt{2}\right).$$

See also PRISM

Octagonal Square Number

A number which is simultaneously OCTAGONAL and SQUARE. Let O_n denote the nth OCTAGONAL NUMBER and T_m the mth SQUARE NUMBER, then a number which is both octagonal and square satisfies the equation $O_n = S_m$, or

$$n(3n - 2) = m^2. \quad (1)$$

COMPLETING THE SQUARE and rearranging gives

$$(3n - 1)^2 - 3m^2 = 1. \quad (2)$$

Therefore, defining

$$x \equiv (3n - 1) \quad (3)$$

$$y \equiv m \quad (4)$$

gives the PELL EQUATION

$$x^2 - 3y^2 = 1 \quad (5)$$

The first few solutions are $(x, y) = (2, 1)$, $(7, 4)$, $(26, 15)$, $(97, 56)$, $(362, 209)$, $(1351, 780)$, ... These give the solutions $(n, m) = (1, 1)$, $(8/3, 4)$, $(9, 15)$, $(98/3, 56)$, $(121, 209)$, ..., of which the integer solutions are (1, 1), (9, 15), (121, 209), (1681, 2911), ... (Sloane's A046184 and A028230), corresponding to the octagonal square numbers 1, 225, 43681, 8473921, 1643897025, ... (Sloane's A036428).

Octagonal Triangular Number

A number which is simultaneously OCTAGONAL and TRIANGULAR. Let O_n denote the nth OCTAGONAL NUMBER and T_m the mth TRIANGULAR NUMBER, then a number which is both octagonal and triangular satisfies the equation $O_n = T_m$, or

$$n(3n - 2) = \tfrac{1}{2}\, m(m + 1). \quad (1)$$

COMPLETING THE SQUARE and rearranging gives

$$8(3n - 1)^2 - 3(2m + 1)^2 = 5. \quad (2)$$

Therefore, defining

$$x \equiv 2(2n - 1) \quad (3)$$

$$y \equiv 2m + 1 \quad (4)$$

gives the second-order Diophantine equation

$$2x^2 - 3y^2 = 5 \quad (5)$$

The first few solutions are $(x, y) = (2, 1)$, $(4, 3)$, $(16, 13)$, $(38, 31)$, $(158, 129)$, $(376, 307)$, ... These give the solutions $(n, m) = (2/3, 0)$, $(1, 1)$, $(3, 6)$, $(20/3, 15)$, $(80/3, 64)$, $(63, 153)$, ..., of which the integer solutions are (1, 1), (3, 6), (63, 153), (261, 638), (6141, 15041), (25543, 62566), (601723, 1473913), ... Octagram

The STAR POLYGON $\{8/3\}$.

Octahedral Graph

A PLATONIC GRAPH on eight nodes. There are 257 topologically distinct octahedral graphs, as first enumerated by Kirkman (1862) and Hermes (1899ab, 1900, 1901; Federico 1969; Duijvestijn and Federico 1981).

Confusingly, the term "octahedral graph" is also used to refer to the 6-vertex POLYHEDRAL GRAPH having the connectivity of the OCTAHEDRON. It is isomorphic to the CIRCULANT GRAPH $Ci_{1,2}(6)$. Several circular embeddings of this graph are illustrated above. The octahedral graph has 6 nodes, 12 edges, VERTEX CONNECTIVITY 4, EDGE CONNECTIVITY 4, GRAPH DIAMETER 2, GRAPH RADIUS 2, and GIRTH 3. It has CHROMATIC POLYNOMIAL

$$\pi_G(z) = z^6 - 12z^5 + 58z^4 - 137z^3 + 154z^2 - 64z,$$

and CHROMATIC NUMBER 3.

Octahedral Group

The POINT GROUP of symmetries of the OCTAHEDRON having order 24 and denoted O_h. It is also the symmetry group of the CUBE, CUBOCTAHEDRON, and TRUNCATED OCTAHEDRON. It has symmetry operations E, $8C_3$, $6C_4$, $6C_2$, $3C_2 = C_4^2$, i, $6S_4$, $8S_6$, $3\sigma_h$, and $6\sigma_4$ (Cotton 1990).

Octahedral Number

A FIGURATE NUMBER which is the sum of two consecutive PYRAMIDAL NUMBERS,

$$O_n = P_{n-1} + P_n = \tfrac{1}{3} n(2n^2 + 1). \qquad (1)$$

The first few are 1, 6, 19, 44, 85, 146, 231, 344, 489, 670, 891, 1156, ... (Sloane's A005900). The GENERATING FUNCTION for the octahedral numbers is

$$\frac{x(x+1)^2}{(x-1)^4} = x + 6x^2 + 19x^3 + 44x^4 + \dots. \qquad (2)$$

A related set of numbers is the number of cubes in the HAUY CONSTRUCTION of the OCTAHEDRON. Each CROSS SECTION has area

$$S_n = n + 2 \sum_{i=1,3,\ldots,n-2} i = \tfrac{1}{2}(n^2+1), \tag{3}$$

where n is an ODD NUMBER, and adding all CROSS SECTIONS gives

$$HO_k = S_k + 2 \sum_{i=1,3,\ldots,k-2} S_i = \tfrac{1}{6}\,k = (k^2+5), \tag{4}$$

for k an ODD NUMBER. Re-indexing so that $k = 2n-1$ gives

$$HO_n = \tfrac{1}{3}(2n-1)(2n^2-2n+3), \tag{5}$$

the first few values of which are 1, 7, 25, 63, 129, ... (Sloane's A001845). These numbers have the GENERATING FUNCTION

$$\begin{aligned} f(x) &= \frac{(1+x)^3}{(1-x)^4} \\ &= 1 + 7x + 25x^2 + 63x^3 + 129x^4 + \ldots. \end{aligned} \tag{6}$$

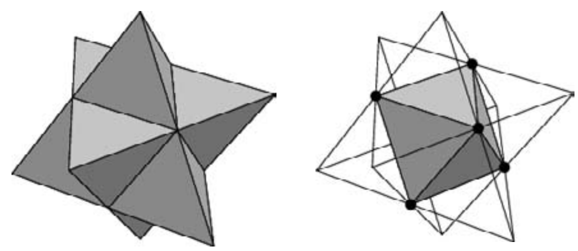
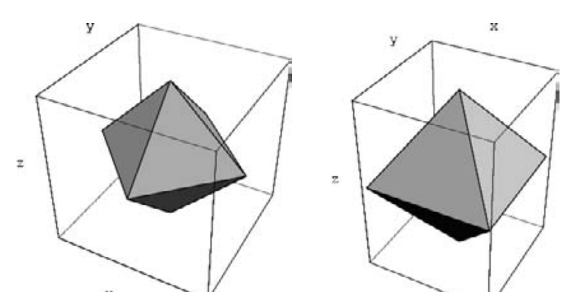
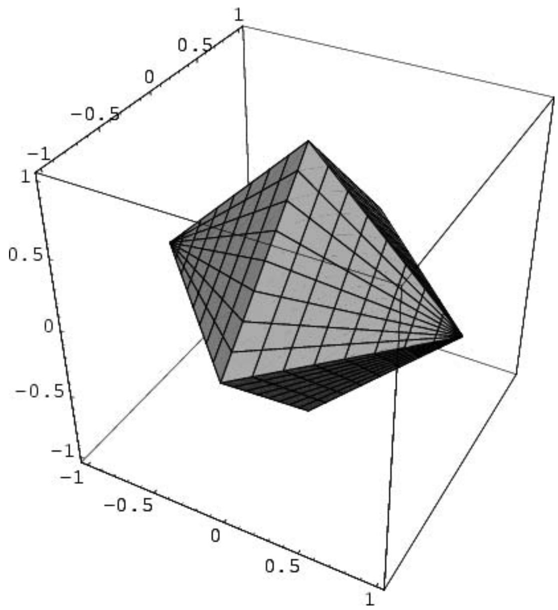
Octahedron



The PLATONIC SOLID P_3 with six VERTICES, 12 EDGES, and eight equivalent EQUILATERAL TRIANGULAR faces, 8{3}. It is also UNIFORM POLYHEDRON U_5 and Wenninger model W_2. It is given by the SCHLÄFLI SYMBOL {3, 4} and WYTHOFF SYMBOL 4|23.



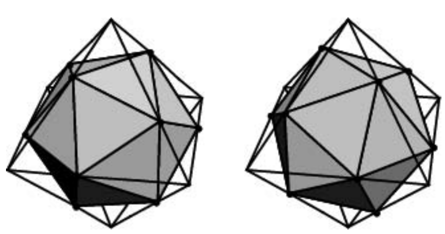
The octahedron of unit side length is the ANTIPRISM of $n = 3$ sides with height $h = \sqrt{6}/3$. The DUAL POLYHEDRON of the octahedron is the CUBE. Like the CUBE, it has the O_h OCTAHEDRAL GROUP of symmetries. The connectivity of the vertices is given by the OCTAHEDRAL GRAPH.



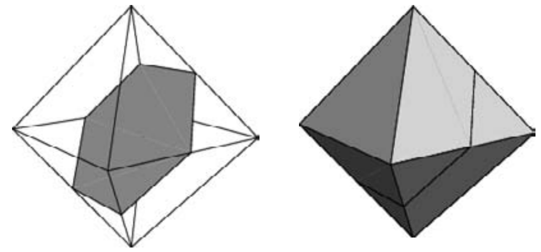
The octahedron has a single STELLATION: the STELLA OCTANGULA. The solid bounded by the two TETRAHEDRA of the STELLA OCTANGULA (left figure) is an octahedron (right figure; Ball and Coxeter 1987).

The following table gives polyhedra which can be constructed by CUMULATION of an octahedron by pyramids of given heights h.

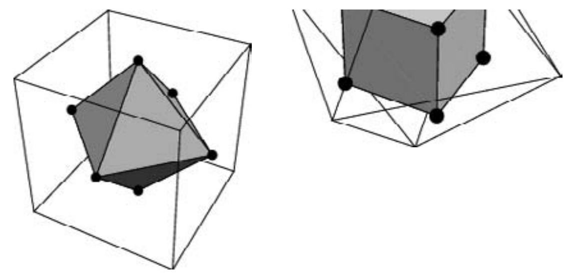
h	$(r+h)/h$	Result
$\sqrt{3} - \frac{2}{3}\sqrt{6}$	$5 - 3\sqrt{2}$	SMALL TRIAKIS OCTAHEDRON
$\frac{1}{3}\sqrt{6}$	3	STELLA OCTANGULA



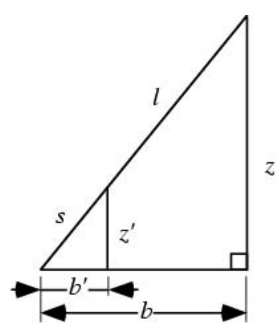
In one orientation (left figure), the VERTICES are given by $(\pm 1, 0, 0)$, $(0, \pm 1, 0)$, $(0, 0, \pm 1)$. In another orientation (right figure), the vertices are $(\pm 1, \pm 1, 0)$ and $(0, 0, \pm\sqrt{2})$.



The face planes are $\pm x \pm y \pm z = 1$, so a solid octahedron is given by the equation



$$|x| + |y| + |z| \leq 1. \tag{1}$$



If the edges of an octahedron are divided in the GOLDEN RATIO such that the points of division for any face form an EQUILATERAL TRIANGLE, then the twelve points of division form an ICOSAHEDRON (Wells 1991). In fact, there are two ways in which the edges can be internally divided in the GOLDEN RATIO and two ways in which they can be externally divided, resulting in four possible icosahedra. Keeping the same connectivity, but reversing the long and short ends of the division gives JESSEN'S ORTHOGONAL ICOSAHEDRON.

A plane PERPENDICULAR to a C_3 axis of an octahedron cuts the solid in a regular HEXAGONAL CROSS SECTION (Holden 1991, pp. 22–23). Since there are four such axes, there are four possible HEXAGONAL CROSS SECTIONS.

The centers of the faces of an octahedron form a CUBE, and the centers of the faces of a CUBE form an octahedron (Steinhaus 1983, pp. 194–195). Faceted forms of the octahedron include the CUBOCTATRUNCATED CUBOCTAHEDRON and TETRAHEMIHEXAHEDRON.

Let an octahedron be length a on a side. The height of the top VERTEX from the square plane is also the CIRCUMRADIUS

$$R = \sqrt{a^2 - d^2}, \tag{2}$$

where

$$d = \tfrac{1}{2}\sqrt{2}a \tag{3}$$

is the diagonal length, so

$$R = \sqrt{a^2 - \tfrac{1}{2}a^2} = \tfrac{1}{2}\sqrt{2}a \approx 0.70710a. \quad (4)$$

Now compute the INRADIUS.

$$\ell = \tfrac{1}{2}\sqrt{3}a \quad (5)$$

$$b = \tfrac{1}{2}a \quad (6)$$

$$s = \tfrac{1}{2}a \tan 30^\circ = \frac{a}{2\sqrt{3}}, \quad (7)$$

so

$$\frac{s}{\ell} = \frac{1}{2\sqrt{3}}\frac{2}{\sqrt{3}} = \tfrac{1}{3}. \quad (8)$$

Use similar TRIANGLES to obtain

$$b' = \frac{s}{\ell}b = \tfrac{1}{6}a \quad (9)$$

$$z' = \frac{s}{\ell}z = \frac{a}{3\sqrt{2}} \quad (10)$$

$$x = b - b' = \tfrac{1}{2}a - \tfrac{1}{6}a = \tfrac{1}{3}a, \quad (11)$$

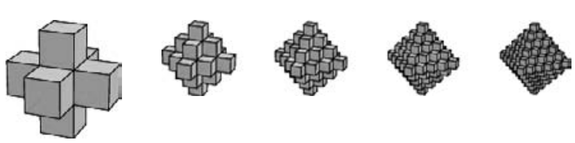
so the INRADIUS is

$$r = \sqrt{x^2 - z'^2} = a\sqrt{\tfrac{1}{9} + \tfrac{1}{18}} = \tfrac{1}{6}\sqrt{6}a \approx 0.40824a, \quad (12)$$

and twice the INRADIUS gives the height of the octahedron viewed as a 3-sided ANTIPRISM. The MIDRADIUS of the octahedron is

$$\rho = \tfrac{1}{2}a = 0.5a. \quad (13)$$

The AREA of one face is the AREA of an EQUILATERAL TRIANGLE



$$A = \tfrac{1}{4}\sqrt{3}a^2. \quad (14)$$

The volume is two times the volume of a square-base pyramid,

$$V = 2\left(\tfrac{1}{3}a^2R\right) = 2\left(\tfrac{1}{3}\right)(a^2)\left(\tfrac{1}{2}\sqrt{2}a\right) = \tfrac{1}{3}\sqrt{2}a^3. \quad (15)$$

The DIHEDRAL ANGLE is

$$\alpha = \cos^{-1}\left(-\tfrac{1}{3}\right) \approx 109.47^\circ. \quad (16)$$

The octahedron can be built using a HAUY CONSTRUCTION. The Hauy octahedral numbers

$$HO_n = \tfrac{1}{3}(2n-1)(2n^2-2n+3) \quad (17)$$

give another method for calculating the VOLUME of the octahedron,

$$V = \lim_{n\to\infty} HO_n\left(\frac{a}{n\sqrt{2}}\right)^3 = \tfrac{1}{3}\sqrt{2}a^3, \quad (18)$$

in agreement with the result derived above.

Octahedron 3-Compound

A POLYHEDRON COMPOUND consisting of three octahedra.

See also OCTAHEDRON, OCTAHEDRON 5-COMPOUND

Octahedron 5-Compound

A POLYHEDRON COMPOUND composed of five OCTAHEDRA occupying the VERTICES of an ICOSAHEDRON. The 30 VERTICES of the compound form an ICOSIDODECAHEDRON (Ball and Coxeter 1987), and the solid is one of the ICOSAHEDRON STELLATIONS (Wenninger 1983). The octahedron 5-compound is the dual of the CUBE 5-COMPOUND.

Constructing the octahedra as the duals of the CUBE 5-COMPOUND where the cubes have unit edge lengths give a solid with edge lengths

$$s_1 = \sqrt{\tfrac{1}{5}\left(3-\sqrt{5}\right)} \tag{1}$$

$$s_2 = 2\sqrt{\tfrac{1}{5}\left(7-3\sqrt{5}\right)} \tag{2}$$

$$s_3 = \sqrt{7-3\sqrt{5}} \tag{3}$$

$$s_4 = 3-\sqrt{5}. \tag{4}$$

The CIRCUMRADIUS is

$$R = 1, \tag{5}$$

and the SURFACE AREA and VOLUME are

$$S = 20\sqrt{3} \tag{6}$$

$$V = \tfrac{20}{3}. \tag{7}$$

The CONVEX HULL of the octahedron 5-compound is the ICOSIDODECAHEDRON.

Odd Divisor Function

The sum of powers of ODD DIVISORS of a number. It is the analog of the DIVISOR FUNCTION for odd divisors only and is written $\sigma_k^{(o)}(n)$. For the case $k = 1$,

$$\sigma_1^{(o)}(n) = \sigma_1(n) - 2\sigma_1(n/2),$$

where $\sigma_k(n/2)$ is defined to be 0 if n is ODD. The following table gives the first few $\sigma_k^{(o)}(n)$.

k	Sloane	$\sigma_k^{(o)}(n)$
0	A001227	1, 1, 2, 1, 2, 2, 2, 1, 3, 2, ...
1	A000593	1, 1, 4, 1, 6, 4, 8, 1, 13, 6, ...

2	A050999	1, 1, 10, 1, 26, 10, 50, 1, 91, 26, ...
3	A051000	1, 1, 28, 1, 126, 28, 344, 1, 757, 126, ...
4	A051001	1, 1, 82, 1, 626, 82, 2402, 1, 6643, 626, ...
5	A051002	1, 1, 244, 1, 3126, 244, 16808, 1, 59293, 3126, ...

This function arises in Ramanujan's EISENSTEIN SERIES $L(q)$ and in a RECURRENCE RELATION for the PARTITION FUNCTION P.

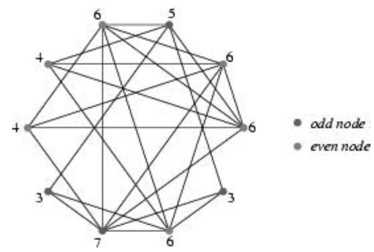
Odd Function

An odd function is a function for which $f(x) = -f(-x)$. An EVEN FUNCTION times an odd function is odd.

Odd Graph

An odd graph O_n is a graph having vertices given by the $n-1$-subsets of $\{1, \dots, 2n-1\}$ such that two vertices are connected by an edge IFF the associated subsets are disjoint (Biggs 1974). The number of nodes in O_n is therefore $\binom{2n-1}{n-1}$, where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT. For $n = 1, 2, \dots$, the first few values are 1, 3, 10, 35, 126, ... (Sloane's A001700).



O_2 is isomorphic to the COMPLETE GRAPH K_3, and O_3 is the PETERSEN GRAPH (Skiena 1990, p. 162).

See also COMPLETE GRAPH, ODD NODE, PETERSEN GRAPH

Odd Node

A NODE in a GRAPH is said to be an odd node if its VERTEX DEGREE is ODD.

See also EVEN NODE, GRAPH, NODE (GRAPH), ODD GRAPH, VERTEX DEGREE

Odd Number

An INTEGER OF THE FORM $N = 2n+1$, where n is an INTEGER. The odd numbers are therefore ..., -3, -1, 1, 3, 5, 7, ... (Sloane's A005408), which are also the GNOMONIC NUMBERS. The GENERATING FUNCTION for the odd numbers is

$$\frac{x(1+x)}{(x-1)^2} = x + 3x^2 + 5x^3 + 7x^4 + \dots.$$

Since the odd numbers leave a remainder of 1 when divided by two, $N \equiv 1 \pmod 2$ for odd N. Integers which are not odd are called EVEN.

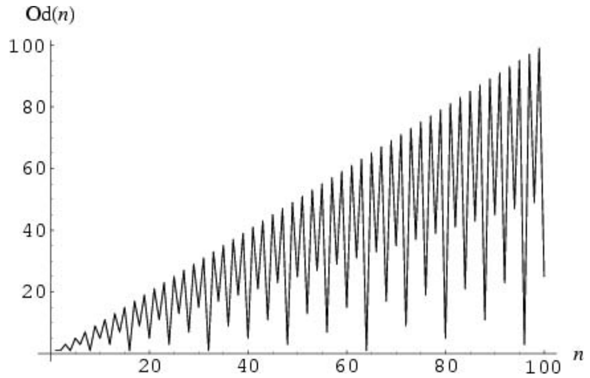
Odd Number Theorem

The sum of the first n ODD NUMBERS is a SQUARE NUMBER:



$$\sum_{k=1}^{n}(2k-1) = 2\sum_{k=1}^{n} k - \sum_{k=1}^{n} 1 = 2\left[\frac{n(n+1)}{2}\right] - n$$
$$= n(n+1) - n = n^2.$$

See also NICOMACHUS'S THEOREM, ODD NUMBER

Odd Order Theorem

FEIT-THOMPSON THEOREM

Odd Part

The odd part Od(n) of a positive integer n is defined by

$$\text{Od}(n) = \frac{n}{2^{b}(n)},$$

where $b(n)$ is the exponent of the exact power of 2 dividing n. Od(n) is therefore the product of odd factors of n. The values for $n = 1, 2, ...$, are 1, 1, 3, 1, 5, 3, 7, 1, 9, 5, 11, ... (Sloane's A000265). The odd part function can be implemented in *Mathematica* as

```
OddPart[n_Integer] := n/
2^IntegerExponent[n,2]
```

Odd Perfect Number

In Book IX of *The Elements,* Euclid gave a method for constructing PERFECT NUMBERS (Dickson 1957, p. 3), although this method applies only to *even* perfect numbers. In a 1638 letter to Mersenne, Descartes proposed that every even perfect number is of Euclid's form, and stated that he saw no reason why an odd perfect number could not exist (Dickson 1957, p. 12). Descartes was therefore among the first to consider the existence off odd perfect numbers; prior to Descartes, many authors had implicitly assumed (without proof) that the perfect numbers generated by Euclid's construction comprised all possible perfect numbers (Dickson 1957, pp. 6–12). In 1657, Frenicle repeated Descartes' belief that every even perfect number is of Euclid's form and that there was no reason odd perfect could not exist. Like Frenicle, Euler also considered odd perfect numbers.

To this day, it is not known if any odd perfect numbers exist, although numbers up to 10^{300} have been checked without success, making the existence of odd perfect numbers appear unlikely (Brent *et al.* 1991; Guy 1994, p. 44). The following table summarizes the development of ever-higher bounds for the smallest possible odd perfect number.

author	bound
Kanold (1957)	10^{20}
Tuckerman (1973)	10^{36}
Hagis (1973)	10^{50}
Brent and Cohen (1989)	10^{160}
Brent *et al.* (1991)	10^{300}

Euler showed that an odd perfect number, if it exists, must be OF THE FORM

$$m = p^{4\lambda+1}Q^2, \quad (1)$$

where p is a prime of the form $4n+1$, a result similar to that derived by Frenicle in 1657 (Dickson 1957, pp. 14 and 19). In 1887, Sylvester conjectured and in 1925, Gradshtein proved that any odd perfect number must have at least six different prime aliquot factors (Ball and Coxeter 1987). If it is not divisible by 3, an odd perfect number must then have at least 11 different prime factors (Hagis 1983). Catalan (1888) proved that if an ODD perfect number is not divisible by 3, 5, or 7, it has at least 26 distinct prime aliquot factors. Stuyvaert (1896) proved that an odd perfect number must be a sum of squares.

UNDULOID

One

1

One-Form

A linear real-valued FUNCTION ω^1 of VECTORS $\mathbf{v}$ such that $\omega^1(\mathbf{v}) \mapsto \mathbb{R}$. VECTORS (i.e., CONTRAVARIANT VECTORS or "KETS" $|\psi\rangle$) and one-forms (i.e., COVARIANT VECTORS or "BRAS" $\langle\phi|$) are DUAL to each other. Therefore

$$\omega^1(\mathbf{v}) \equiv \mathbf{v}(\omega^1) \equiv \langle\omega^1, \mathbf{v}\rangle = \langle\phi|\psi\rangle.$$

The operation of applying the one-form to a VECTOR $\omega^1(\mathbf{v})$ is called CONTRACTION.

Toussaint, G. "Anthropomorphic Polygons." *Amer. Math. Monthly* **122**, 31–35, 1991.

One-Ninth Constant

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Let $\lambda_{m,n}$ be CHEBYSHEV CONSTANTS. Schönhage (1973) proved that

$$\lim_{n\to\infty}(\lambda_{0,n})^{1/n} = \tfrac{1}{3}. \tag{1}$$

It was conjectured that

$$\Lambda \equiv \lim_{n\to\infty}(\lambda_{n,n})^{1/n} = \tfrac{1}{9}. \tag{2}$$

Carpenter *et al.* (1984) obtained

$$\Lambda = 0.1076539192\ldots \tag{3}$$

numerically. Gonchar and Rakhmanov (1980) showed that the limit exists and disproved the 1/9 conjecture, showing that Λ is given by

$$\Lambda = \exp\left[-\frac{\pi K\left(\sqrt{1-c^2}\right)}{K(c)}\right], \tag{4}$$

where K is the complete ELLIPTIC INTEGRAL OF THE FIRST KIND, and $c = 0.9089085575485414\ldots$ is the PARAMETER which solves

$$K(k) = 2E(k), \tag{5}$$

and E is the complete ELLIPTIC INTEGRAL OF THE SECOND KIND. This gives the value for Λ computed by Carpenter *et al.* (1984) Λ is also given by the unique POSITIVE ROOT of

$$f(z) = \tfrac{1}{8}, \tag{6}$$

where

$$f(z) \equiv \sum_{j=1}^{\infty} a_j z^j \tag{7}$$

and

$$a_j = \left| \sum_{d \mid j} (-1)^d d \right| \tag{8}$$

(Gonchar and Rakhmanov 1980). a_j may also be computed by writing j as

$$j = 2^m p_1^{m_1} p_2^{m_2} \cdots p_k^{m_k}, \tag{9}$$

where $m \geq 0$ and $m_i \geq 1$, then

$$a_j = \left|2^{m+1} - 3\right| \times \frac{p_1^{m_1+1} - 1}{p_1 - 1} \frac{p_2^{m_2+1} - 1}{p_2 - 1} \cdots \frac{p_k^{m_k+1} - 1}{p_k - 1} \tag{10}$$

(Gonchar 1990). Yet another equation for Λ is due to Magnus (1986). Λ is the unique solution with $x \in (0,\ 1)$ of

$$\sum_{k=0}^{\infty} (2k+1)^2 (-x)^{k(k+1)/2} = 0, \tag{11}$$

an equation which had been studied and whose root had been computed by Halphen (1886). It has therefore been suggested (Varga 1990) that the constant be called the HALPHEN CONSTANT. $1/\Lambda$ is sometimes called VARGA'S CONSTANT.

One-to-One

one-to-one and not onto (injection but not surjection)

Let f be a FUNCTION defined on a SET A and taking values in a set B. Then f is said to be one-to-one (a.k.a. an injection or embedding) if, whenever $f(x) = f(y)$, it must be the case that $x = y$. In other words, f is one-to-one if it MAPS distinct objects to distinct objects.

If the function is a linear OPERATOR which assigns a unique MAP to each value in a VECTOR SPACE, it is called one-to-one. Specifically, given a VECTOR SPACE $\mathbb{V}$ with $\mathbf{X}, \mathbf{Y} \in \mathbb{V}$, then a TRANSFORMATION T defined on $\mathbb{V}$ is one-to-one if $T(\mathbf{X}) \neq T(\mathbf{Y})$ for all $\mathbf{X} \neq \mathbf{Y}$.

one-to-one and onto (bijection)

A function which is both one-to-one and ONTO is said to be a BIJECTION.

See also BIJECTION, DOMAIN, MANY-TO-ONE, ONTO,

RANGE (IMAGE)

One-Way Function

Informally, a function f is a one-way function if

1. The description of f is publicly known and does not require any secret information for its operation.
2. Given x, it is easy to compute $f(x)$.
3. Given y, in the range of f, it is hard to find an x such that $f(x)=y$. More precisely, any efficient algorithm (solving a P-PROBLEM succeeds in inverting f with negligible probability.

The existence of one-way functions is not proven. If true, it would imply $P \neq NP$. Therefore, it would answer the COMPLEXITY THEORY NP-PROBLEM question of whether all apparently NP-problems are actually P-problems. Yet a number of conjectured one-way functions are routinely used in commerce and industry. For example, it is conjectured, but not proved, that the following are one-way functions:

1. Factoring problem: $f(p, q)=pq$, for randomly chosen primes p, q.
2. Discrete logarithm problem: $f(p, g, x)=\langle p, g, g^x \pmod p\rangle$, for g a generator of $\mathbb{Z}_p{}^*$, for some prime p.
3. Discrete root extraction problem: $f(p, q, e, y)=\langle pq, e, y^e \pmod{pq}\rangle$, for y in $\mathbb{Z}_{pq}{}^*$, e in $\mathbb{Z}_{pq}$ and relatively prime to $(p-1)(q-1)$, and p, q primes. This is the function commonly known as RSA ENCRYPTION.
4. SUBSET SUM PROBLEM: $f(a, b)=\langle \Sigma_{i=1}^n a_i b_i, b\rangle$, for $a_i \in \{0, 1\}$, and n-bit integers b_i.
5. QUADRATIC RESIDUE problem.

See also NP-PROBLEM, ONE-WAY HASH FUNCTION, P-PROBLEM, QUADRATIC RESIDUE, RSA ENCRYPTION, SUBSET SUM PROBLEM

Only Critical Point in Town Test

If a univariate REAL FUNCTION $f(x)$ has a single CRITICAL POINT and that point is a LOCAL MAXIMUM, then $f(x)$ has its GLOBAL MAXIMUM there (Wagon 1991, p. 87). The test breaks downs for bivariate functions, but does hold for bivariate *polynomials* of degree ≤ 4. Such exceptions include

$$z=3xe^y-x^3-e^{3y} \tag{1}$$

$$z=x^2(1+y)^3+y^2 \tag{2}$$

$$z=\begin{cases}\dfrac{xy(x^2-y^2)}{x^2+y^2} & \text{for } (x, y)\neq(0, 0)\\ 0 & \text{for } (x, y)=(0, 0)\end{cases} \tag{3}$$

(Rosenholtz and Smylie 1985, Wagon 1991). Note that equation (3) has discontinuous PARTIAL DERIVATIVES z_{xy} and z_{yx}, and $z_{yx}(0, 0)=1$ and $z_{xy}(0, 0)=1$.

Ono Inequality

Ono (1914) conjectured that the inequality

$$27(b^2+c^2-a^2)^2(a^2+c^2-b^2)^2(a^2+b^2-c^2)^2 \leq (4K)^6$$

holds true for all TRIANGLES, where a, b, and c are the lengths of the sides and K is the AREA of the TRIANGLE. This conjecture was shown to be false by Quijano (1915), although it was subsequently proved to be true for ACUTE TRIANGLES by Balitrand (1916). A simple counterexample is provided by the triangle with $a=3/4$, $b=1/2$, and $c=1$.

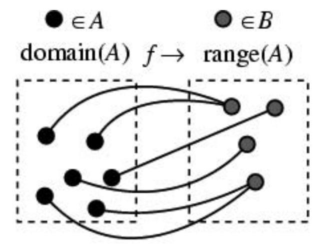
Onsager Differential Equation

The ordinary Onsager equation is the sixth-order ORDINARY DIFFERENTIAL EQUATION

$$\frac{d^3}{dx^3}\left[e^x \frac{d^2}{dx^2}\left(e^x \frac{dy}{dx}\right)\right]=f(x)$$

(Vicelli 1983; Zwillinger 1997, p. 128), while the partial Onsager equation is given by the PARTIAL DIFFERENTIAL EQUATION



$$(e^x(e^x u_{xx})_{xx})_{xx}+B^2 u_{yy}=F(x,\ y)$$

(Wood and Martin 1980; Zwillinger 1997, p. 129).

Onto

onto and not one-to-one
(surjection but not injection)

Let f be a FUNCTION defined on a SET A and taking values in a set B. Then f is said to be onto (a.k.a. a surjection) if, for any $b \in B$, there exists an $a \in A$ for which $b=f(a)$.

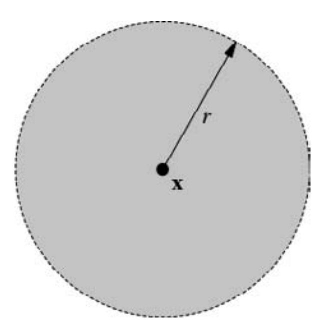
Let the function be an OPERATOR which MAPS points in the DOMAIN to every point in the RANGE and let $\mathbb{V}$ be a VECTOR SPACE with $\mathbf{X}$, $\mathbf{Y} \in \mathbb{V}$. Then a TRANSFORMATION T defined on $\mathbb{V}$ is onto if there is an $\mathbf{X} \in \mathbb{V}$ such that $T(\mathbf{X})=\mathbf{Y}$ for all $\mathbf{Y}$.

See also BIJECTION, DOMAIN, MANY-TO-ONE, ONE-TO-ONE, RANGE (IMAGE)

Open Ball

An n-D open ball of RADIUS r is the collection of points of distance less than r from a fixed point in EUCLIDEAN n-space. Explicitly, the closed ball with center $\mathbf{x}$ and radius r is defined by

$$B_r(\mathbf{x})=\{\mathbf{y} : |\mathbf{y}-\mathbf{x}|<r\}.$$



The open ball for $n=1$ is called an OPEN INTERVAL, and the term OPEN DISK is sometimes used for $n=2$ and sometimes as a synonym for open ball.

See also BALL, CLOSED DISK, OPEN DISK, OPEN INTERVAL, OPEN SET

References

Croft, H. T.; Falconer, K. J.; and Guy, R. K. *Unsolved Problems in Geometry.* New York: Springer-Verlag, p. 1, 1991.

Open Disk

An n-D open disk of RADIUS r is the collection of

points of distance less than r from a fixed point in EUCLIDEAN n-space. Krantz (1999, p. 3) uses the symbol $D(\mathbf{x}, r)$ to denote the open disk, and $D = D(0, 1)$ to denote the unit open disk centered at the origin.
The open disk for $n = 1$ is called an OPEN INTERVAL, and the term OPEN BALL is often used for $n \geq 3$.

See also CLOSED DISK, DISK, OPEN BALL, OPEN INTERVAL, OPEN SET, PERFORATION

References

Krantz, S. G. *Handbook of Complex Analysis.* Boston, MA: Birkhäuser, p. 3, 1999.

Open Interval

open interval (a, b)

An INTERVAL which does not include its LIMIT POINTS, denoted (a, b). The non-standard notation $]a, b[$ is sometimes also used.

See also CLOSED INTERVAL, HALF-CLOSED INTERVAL, INTERVAL, OPEN DISK, OPEN SET

References

Open Problems

UNSOLVED PROBLEMS

Open Set

open interval *open disk*

A SET is open if every point in the set has a NEIGHBORHOOD lying in the set. An open set of RADIUS r and center $\mathbf{x}_0$ is the set of all points $\mathbf{x}$ such that $|\mathbf{x} - \mathbf{x}_0| < r$, and is denoted $D_r(\mathbf{x}_0)$. In 1-space, the open set is an OPEN INTERVAL. In 2-space, the open set is a DISK. In 3-space, the open set is a BALL.
More generally, given a TOPOLOGY (consisting of a SET X and a collection of SUBSETS T), a SET is said to be open if it is in T. Therefore, while it is not possible for a set to be both finite and open in the TOPOLOGY of the REAL LINE (a single point is a CLOSED SET), it is possible for a more general topological SET to be both finite and open.

The complement of an open set is a CLOSED SET. It is possible for a set to be neither open nor CLOSED, e.g., the HALF-CLOSED INTERVAL $(0, 1]$.

Operator

An operator $A : f^{(n)}(I) \mapsto f(I)$ assigns to every function $f \in f^{(n)}(I)$ a function $A(f) \in f(I)$. It is therefore a mapping between two FUNCTION SPACES. If the range is on the REAL LINE or in the COMPLEX PLANE, the mapping is usually called a FUNCTIONAL instead.

Optimum

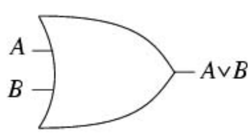
EXTREMUM

Or

A term in LOGIC which yields TRUE if any one of a sequence conditions is TRUE, and FALSE if *all* conditions are FALSE. b OR $+\left(\frac{12}{35}\epsilon^2 - \frac{96}{385}\epsilon^3\right)P_4 - \frac{40}{231}\epsilon^3 P_6 + \ldots$ is denoted $27(b^2+c^2-a^2)^2(a^2+c^2-b^2)^2(a^2+b^2-c^2)^2 \leq (4K)^6$,

$a=3/4$, or $b=1/2$. The symbol $\vee$ derives from the first letter of the Latin word "vel" meaning "or." The BINARY OR operator has the following TRUTH TABLE.

b	$+\left(\frac{12}{35}\,\epsilon^2-\frac{96}{385}\,\epsilon^3\right)P_4-\frac{40}{231}\,\epsilon^3P_6+\ldots.$	$b=1/2$
F	F	F
F	T	T
T	F	T
T	T	T



A product of ORs is called a DISJUNCTION and is denoted

$$\frac{d^3}{dx^3}\left[e^x\,\frac{d^2}{dx^2}\left(e^x\,\frac{dy}{dx}\right)\right]=f(x)$$

Two BINARY numbers can have the operation OR performed bitwise. This operation is sometimes denoted $27(b^2+c^2-a^2)^2(a^2+c^2-b^2)^2(a^2+b^2-c^2)^2 \le (4K)^6$.

See also AND, BINARY OPERATOR, LOGIC, NOT, PREDICATE, TRUTH TABLE, UNION, XOR

OR

OR gate

A CONNECTIVE in LOGIC which yields TRUE if any one of a sequence conditions is TRUE, and FALSE if *all* conditions are FALSE. In formal logic, the term DISJUNCTION (or, more specifically, inclusive disjunction) is commonly used to describe the OR operator. A OR B is denoted $A \vee B$ (Mendelson 1997, p. 13), $A|B$, $A+B$ (Simpson 1987, p. 539), or $A \cup B$ (Simpson 1987, p. 539). The circuit diagram symbol for an OR gate is illustrated above.

The symbol $\vee$ derives from the first letter of the Latin word "vel," meaning "or," and the expression $A \vee B$ is voiced either "A or B" or "A vel B." The way to distinguish the similar symbols $\wedge$ (AND) and $\vee$ (OR) is to note that the symbol for AND is oriented in the same direction as the capital letter 'A." The OR operation is implemented in *Mathematica* as Or[A, B, ...].

The OR operation can be written in terms of NOT and AND as

$$A \vee B = !(!A \wedge !B)$$

(Mendelson 1997, p. 26).

The BINARY OR operator has the following TRUTH TABLE (Carnap 1958, p. 10; Simpson 1987, p. 542; Mendelson 1997, p. 13).

A	B	$A \vee B$
T	T	T
T	F	T
F	T	T
F	F	F

A product of ORs is called a DISJUNCTION and is denoted

$$\bigvee_{k=1}^{n} A_k.$$

For example, the TRUTH TABLE for the ternary OR operator is shown below (Simpson 1987, p. 543).

A	B	C	$A \vee B \vee C$
T	T	T	T
T	T	F	T
T	F	T	T
T	F	F	T
F	T	T	T
F	T	F	T
F	F	T	T
F	F	F	F

Two BINARY numbers can have the operation OR performed bitwise. This operation is sometimes denoted $A|B$.

Fineman, M. *The Nature of Visual Illusion.* New York: Dover, p. 153, 1996.

Orbit (Group)

In celestial mechanics, the fixed path a planet traces as it moves around the sun is called an orbit. When a GROUP G acts on a set X (this process is called a GROUP ACTION), it permutes the elements of X. Any particular element X moves around in a fixed path, which is called its orbit. In the notation of set theory, a group orbit can be defined as

$$G(x) = \{gx \in X : g \in G\}.$$

Note that if $y \in G(x)$ then $x \in G(y)$, because $y = gx$ IFF $x = g^{-1}y$. Consequently, the orbits PARTITION X and, given a PERMUTATION GROUP G on a set S, the orbit of an element $s \in S$ is the subset of S consisting of elements to which some element G can send s. Note that a FIXED POINT is an orbit consisting of a single element.

For example, consider the action by the circle group $\mathbb{S}^1$ on the SPHERE $\mathbb{S}^2$ by rotations along its axis. Then the north pole is an orbit, as is the south pole. The equator is a one-dimensional orbit, as is a general orbit, corresponding to a line of latitude.

Orbits of a LIE GROUP action may look different from each other. For example, $O(1, 1)$, the ORTHOGONAL GROUP of SIGNATURE $(1, 1)$, acts on the plane. It has three different kinds of orbits: the origin (a FIXED POINT, the four rays $\{(\pm t, \pm t), t > 0\}$, and the hyperbolas such as $y^2 - x^2 = 1$. In general, an orbit may be of any dimension, up to the dimension of the LIE GROUP. If the LIE GROUP G is COMPACT, then its orbits are SUBMANIFOLDS.

The group's action on the orbit through x is TRANSITIVE, and so is related to its ISOTROPY GROUP. In particular, the cosets of the isotropy subgroup correspond to the elements in the orbit,

$$G(x) \sim G/G_x.$$

Orbit (Map)

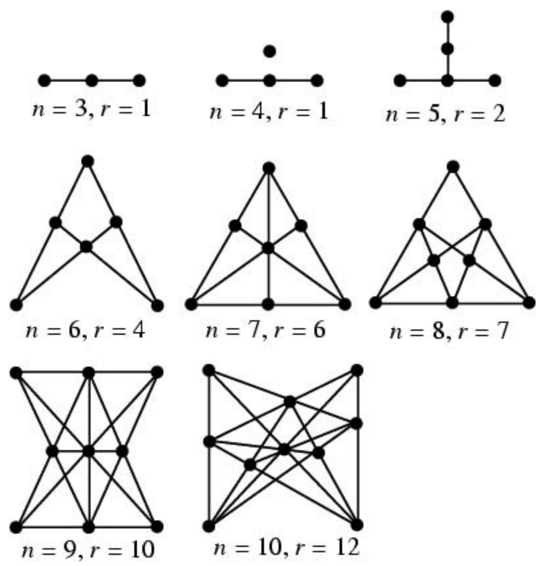
The SEQUENCE generated by repeated application of a MAP. The MAP is said to have a closed orbit if it has a finite number of elements.

See also DYNAMICAL SYSTEM, SINK (MAP)

Orbit (Permutation)

CYCLE (PERMUTATION)

Orchard Visibility Problem



A tree is planted at each LATTICE POINT in a circular orchard which has CENTER at the ORIGIN and RADIUS r. If the radius of trees exceeds $1/r$ units, one is unable to see out of the orchard in any direction. However, if the RADII of the trees are $< 1/\sqrt{r^2+1}$, one can see out at certain ANGLES.

See also LATTICE POINT, ORCHARD-PLANTING PROBLEM, VISIBILITY

References

Honsberger, R. "The Orchard Problem." Ch. 4 in *Mathematical Gems I.* Washington, DC: Math. Assoc. Amer., pp. 43–52, 1973.

Orchard-Planting Problem

Also known as the TREE-PLANTING PROBLEM. Plant n trees so that there will be r straight rows with k trees in each row. The following table gives $\max(r)$ for various k. $k = 3$ is Sloane's A003035 and $k = 4$ is Sloane's A006065.

n	$k = 3$	$k = 4$	$k = 5$
3	1	–	–
4	1	1	–
5	2	1	1
6	4	1	1
7	6	2	1
8	7	2	1
9	10	3	2
10	12	5	2
11	16	6	2
12	19	7	3
13	[22, 24]	≥ 9	3
14	[26, 27]	≥ 10	4
15	[31, 32]	≥ 12	≥ 6
16	37	≥ 15	≥ 6
17	[40, 42]	≥ 15	≥ 7
18	[46, 48]	≥ 18	≥ 9
19	[52, 54]	≥ 19	≥ 10
20	[57, 60]	≥ 21	≥ 11
21	[64, 67]		
22	[70, 73]		
23	[77, 81]		
24	[85, 88]		
25	[92, 96]		

Sylvester showed that

$$r(k=3) \geq \left\lfloor \frac{1}{6}(n-1)(n-2) \right\rfloor,$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION (Ball and Coxeter 1987). Burr, Grünbaum and Sloane (1974) have shown using cubic curves that

$$r(k=3) \leq 1 + \left\lfloor \frac{1}{6} n(n-3) \right\rfloor,$$

except for $n = 7$, 11, 16, and 19, and conjecture that the inequality is an equality with the exception of the preceding cases. For $n \geq 4$,

$$r(k=3) \geq \left\lfloor \frac{1}{3} \left\lfloor \frac{1}{2} n(n-1) - \left\lceil \frac{3}{7} n \right\rceil \right\rfloor \right\rfloor,$$

where $\lceil x \rceil$ is the CEILING FUNCTION.

Order (Conjugacy Class)

The number of elements of a GROUP in a given CONJUGACY CLASS.

Order (Difference Set)

Let G be GROUP of ORDER h and D be a set of k elements of G. If the set of differences $d_i - d_j$ contains every NONZERO element of G exactly λ times, then D is a (h, k, λ)-difference set in G of order $n = k - \lambda$.

Order (Field)

The number of elements in a FINITE FIELD.

Order (Function)

The INFIMUM of all number a for which

$$|f(z)| \leq \exp(|z|^a)$$

holds for all $|z| > r$ and f an ENTIRE FUNCTION, is called the ORDER of f, denoted $\lambda = \lambda(f)$ (Krantz 1999, p. 121).

See also ENTIRE FUNCTION, FINITE ORDER

Order (Graph)

The number of nodes in a graph is called its order.

See also GRAPH

References

Skiena, S. *Implementing Discrete Mathematics: Combinatorics and Graph Theory with Mathematica.* Reading, MA: Addison-Wesley, p. 82, 1990.

Order (Group)

The number of elements in a GROUP G, denoted $|G|$. If the order of a GROUP is a finite number, the group is said to be a FINITE GROUP.

The order of an element g of a FINITE GROUP G is the smallest POWER of n such that $g^n = I$, where I is the IDENTITY ELEMENT. In general, finding the order of the element of a group is at least as hard as factoring (Meijer 1996). However, the problem becomes significantly easier if $|G|$ and the factorization of $|G|$ are known. Under these circumstances, efficient ALGORITHMS are known (Cohen 1993).

Order (Modulo)

For an INTEGER n that is RELATIVELY PRIME to a number a, there exists a smallest exponent $k \geq 1$ such that $a^k \equiv 1 \pmod{n}$, and k is called the order (or HAUPT-EXPONENT) of a modulo n. For example, the order of 2 modulo 7 is 3, since $2^1 \equiv 2$, $2^2 \equiv 4$, and $2^3 = 8 \equiv 1 \pmod{7}$.

Order (Ordinary Differential Equation)

An ordinary differential equation of order n is an equation of the form

$$F(x, y, y', \ldots, y^{(n)}) = 0.$$

Order (Permutation)

Permutation

Order (Polynomial)

The highest order power in a univariate polynomial is known as its order (or, more properly, its degree). For example, the polynomial

$$P(x) = a_n x^n + \ldots + a_2 x^2 + a_1 x + a_0$$

is of order n, denoted $\deg P(x) = n$. The order of a polynomial is implemented in *Mathematica* as Exponent[*poly*, *x*].

It is preferable to use the word "degree" for the highest exponent in a polynomial, since a completely different meaning is given to the word "order" in polynomials taken modulo some integer (where this meaning is the one used in the order of a modulus). In particular, the order of a polynomial $P(x)$ with $P(0) \neq 0$ is the smallest integer e for which $P(x)$ divides $x^e + 1$. For example, in the finite field GF(2), the order of $x^5 + x^2 + 1$ is 31, since

$$\frac{x^{31}+1}{x^5+x^2+1} = 1 + x^2 + x^4 + x^5 + x^6 + x^8 + x^9 + x^{13} + x^{14} + x^{15} + x^{16} + x^{17} + x^{20} + x^{21} + x^{23} + x^{26} \pmod 2.$$

This concept is closely related to that of the haupt-exponent.

See also Degree (Polynomial), Haupt-Exponent, Irreducible Polynomial, Order (Modulo), Primitive Polynomial

Order (Root)

Multiplicity

Order (Tensor)

Rank (Tensor)

Order (Vertex)

The number of edges meeting at a given node in a graph is called the order of that vertex.

Order (Zero)

Multiplicity

Order Isomorphic

Two totally ordered sets $(A, \leq)$ and $(B, \leq)$ are order isomorphic iff there is a bijection f from A to B such that for all $a_1, a_2 \in A$,

$$a_1 \leq a_2 \text{ iff } f(a_1) \leq f(a_2)$$

(Ciesielski 1997, p. 38). In other words, A and B are equipollent ("the same size") and there is an order preserving mapping between the two.

Dauben (1979) and Suppes (1972) call this property "similar." The definition works equally well on partially ordered sets.

Order of Magnitude

Physicists and engineers use the phrase "order of magnitude" to refer to the smallest power of ten needed to represent a quantity. Two quantities which are within about a factor of 10 of each other are then said to be "of the same order of magnitude." Hardy and Wright (1979, p. 7) use the term to mean asymptotic to.

See also Asymptotic, Asymptotic Notation

Order Statistic

Given a sample of n variates $X_1, ..., X_n$, reorder them so that $X'_1 < X'_2 < \ldots < X'_n$. Then the ith order statistic $X^{\langle i \rangle}$ is defined as X'_i, with the special cases

$$m_n = X^{\langle 1 \rangle} = \min_j (X_j)$$

$$M_n = X^{\langle n \rangle} = \max_j (X_j).$$

A robust estimation technique based on linear

COMBINATIONS of order statistics is called an L-ESTIMATE.

Order Type

Every TOTALLY ORDERED SET $(A, \leq)$ is associated with a so-called order type. Two sets A and B are said to have the same order type IFF they are ORDER ISOMORPHIC (Ciesielski 1997, p. 38; Dauben 1990, pp. 184 and 199; Moore 1982, p. 52; Suppes 1972, pp. 127–129). Thus, an order type categorizes TOTALLY ORDERED SETS in the same way that a CARDINAL NUMBER categorizes sets. The term is due to Georg Cantor, and the definition works equally well on PARTIALLY ORDERED SETS.

The order type of the negative integers is called $^*\omega$ (Moore 1982, p. 62), although Suppes (1972, p. 128) calls it ω^*. The order type of the rationals is called η (Dauben 1990, p. 152; Moore 1982, p. 115; Suppes 1972, p. 128). Some sources call the order type of the reals θ (Dauben 1990, p. 152), while others call it λ (Suppes 1972, p. 128).

In general, if α is any order type, then $^*\alpha$ is the same type ordered backwards (Dauben 1990, p. 153).

Ordered Factorization

An ordered factorization is a factorization (not necessarily into prime factors) in which $a \times b$ is considered distinct from $b \times a$. The number of ordered factorizations of n is equal to the number of PERFECT PARTITIONS of $n-1$ (Goulden and Jackson 1983, p. 94).

See also PERFECT PARTITION

References

Ordered Geometry

A GEOMETRY constructed without reference to measurement. The only primitive concepts are those of points and intermediacy. There are 10 AXIOMS underlying ordered GEOMETRY.

See also ABSOLUTE GEOMETRY, AFFINE GEOMETRY, GEOMETRY

Ordered List

The number of nondecreasing lists $\{a_1, a_2, \ldots, a_n\}$ consisting of n elements $1 \leq a_i \leq k$ is given by the binomial coefficient

$$N(n, k) = \binom{n+k-1}{n-1}.$$

For example, there are six nondecreasing lists of length 2 for elements chosen from 1 to 3: (1, 1), (1, 2), (1, 3), (2, 2), (2, 3), and (3,3).

Ordered Pair

A PAIR of quantities (a, b) where ordering is significant, so (a, b) is considered distinct from (b, a) for $a \neq b$.

See also LIST, MULTISET, ORDERED PAIRS REPRESENTATION, PAIR, SET, VECTOR

Ordered Pairs Representation

A representation of a GRAPH in which edges are specified as ordered pairs (for a DIRECTED GRAPH), or unordered pairs (for an UNDIRECTED GRAPH). The ordered pairs representation of a graph g may be computed using `ToOrderedPairs`[g] in the *Mathematica* add-on package ``DiscreteMath`Combinatorica` `` (which can be loaded with the command ``<<DiscreteMath` ``) or `ToUnorderedPairs`[g]. A graph may be constructed from ordered pairs using `FromOrderedPairs`[l], or from unordered pairs using `FromUnorderedPairs`[l].

Skiena, S. "Ordered Pairs." §3.1.3 in *Implementing Discrete Mathematics: Combinatorics and Graph Theory with Mathematica.* Reading, MA: Addison-Wesley, pp. 87–88, 1990.

Ordered Set

An ambiguous term which is sometimes used to mean a PARTIALLY ORDERED SET and sometimes to mean a TOTALLY ORDERED SET.

Ordered Tree

A ROOTED TREE in which the order of the subtrees is significant. There is a ONE-TO-ONE correspondence between ordered FORESTS with n nodes and BINARY TREES with n nodes.

See also BINARY TREE, FOREST, ROOTED TREE

Ordering

The number of "ARRANGEMENTS" in an ordering of n items is given by either a COMBINATION (order is ignored) or a PERMUTATION (order is significant).

See also ARRANGEMENT, COMBINATION, CUTTING, DERANGEMENT, PARTIAL ORDER, PERMUTATION, SORTING, TOTAL ORDER

Ordering Axioms

The four of HILBERT'S AXIOMS which concern the arrangement of points.

Ordinal

ORDINAL NUMBER

Ordinal Addition

Let $(A, \leq)$ and $(B, \leq)$ be disjoint TOTALLY ORDERED SETS with ORDER TYPES α and β. Then the ordinal sum is defined at set $(C = A \cup B, \leq)$ where, if c_1 and c_2 are both from the same SUBSET, the order is the same as in the subset, but if c_1 is from A and c_2 is from B, then $c_1 < c_2$ has ORDER TYPE $\alpha + \beta$ (Ciesielski 1997, p. 48; Dauben 1990, p. 104; Moore 1982, p. 40).

One should note that in the infinite case, ORDER TYPE addition is not commutative, although it is associative. For example,

$$1 + \omega = \omega \neq \omega + 1.$$

In addition, $\{a\} \cup \{0, 1, 2, 3, \ldots\}$, with a the least element, is ORDER ISOMORPHIC to $\{0, 1, 2, 3, \ldots\}$, but not to $\{0, 1, 2, 3, \ldots\} \cup \{a\}$, with a the greatest element, since it has a greatest element and the other does not.

An inductive definition for ordinal addition states that for any ORDINAL NUMBER α,

$$\alpha + 0 = \alpha, \qquad (1)$$

and

$$\alpha + (\text{successor to } \beta) = \text{the successor to } (\alpha + \beta). \qquad (2)$$

If β is a LIMIT ORDINAL, then $\alpha + \beta$ is the least ordinal greater than any ordinal in the set $\{\alpha + \gamma : \gamma < \beta\}$ (Rubin 1967, p. 188; Suppes 1972, p. 205).

Ordinal Comparison

Let $(A, \leq)$ and $(B, \leq)$ be WELL ORDERED SETS with ORDINAL NUMBERS α and β. Then $\alpha < \beta$ IFF A is ORDER ISOMORPHIC to an INITIAL SEGMENT of B (Dauben 1990, p. 199). From this, it can easily be shown that the ORDINAL NUMBERS are TOTALLY ORDERED by the relation. In fact, they are WELL ORDERED by the relation.

See also WELL ORDERED SET

References

Dauben, J. W. *Georg Cantor: His Mathematics and Philosophy of the Infinite.* Princeton, NJ: Princeton University Press, 1990.

Ordinal Exponentiation

Let α and β be any ORDINAL NUMBERS, then ordinal exponentiation is defined so that if $\beta = 0$ then $\alpha^\beta = 1$. If β is not a LIMIT ORDINAL, then choose γ such that $\gamma + 1 = \beta$,

$$alpha^{(\text{successor of } \beta)}(\alpha^\beta) * a.$$

If β is a LIMIT ORDINAL, then if $\alpha = 0$, $\alpha^\beta = 0$. If $\alpha \neq 0$ then, α^β is the least ordinal greater than any ordinal in the set $\{\alpha^\gamma : \gamma < \beta\}$ (Rubin 1967, p. 204; Suppes 1972, p. 215).

Note that this definition is not analogous to the definition for cardinals, since $|\alpha|^{|\beta|}$ may not equal $|\alpha^\beta|$, even though $|\alpha| + |\beta| = |\alpha + \beta|$ and $|\alpha| * |\beta| = |\alpha * \beta|$. Note also that $2^\omega = \omega$.

A familiar example of ordinal exponentiation is the definition of Cantor's first epsilon number. ϵ_0 is the least ordinal such that $\omega^{\epsilon_0} = \epsilon_0$. It can be shown that it is the least ordinal greater than any ordinal in $\{\omega, \omega^\omega, \omega^{\omega^\omega}, \ldots\}$.

Ordinal Multiplication

Let $(A, \leq)$ and $(B, \leq)$ be TOTALLY ORDERED SETS. Let $C = A \times B$ be the CARTESIAN PRODUCT and define order as follows. For any $a_1, a_2 \in A$ and $b_1, b_2 \in B$,

1. If $a_1 < a_2$, then $(a_1, b_1) < (a_2, b_2)$,
2. If $a_1 = a_2$, then (a_1, b_1) and (a_2, b_2) compare the same way as b_1, b_2 (i.e., lexicographical order)

(Ciesielski 1997, p. 48; Rubin 1967; Suppes 1972). However, Dauben (1990, p. 104) and Moore (1982, p. 40) define multiplication in the reverse order.

Like addition, multiplication is not commutative, but it is associative,

$$2 * \omega = \omega \neq \omega * 2. \tag{1}$$

An inductive definition for ordinal multiplication states that for any ORDINAL NUMBER α,

$$\alpha * 0 = 0 \tag{2}$$

$$\alpha * (\text{successor to beta}) = \alpha * \beta + \alpha. \tag{3}$$

If β is a LIMIT ORDINAL, then $\alpha + \beta$ is the least ordinal greater than any ordinal in the set $\{\alpha * \gamma : \gamma < \beta\}$ (Suppes 1972, p. 212).

Ordinal Number

In common usage, an ordinal number is an adjective which describes the numerical position of an object, e.g., first, second, third, etc.

In formal SET THEORY, an ordinal number (sometimes simply called an "ordinal" for short) is one of the numbers in Georg Cantor's extension of the WHOLE NUMBERS. An ordinal number is defined as the ORDER TYPE of a WELL ORDERED SET (Dauben 1990, p. 199; Moore 1982, p. 52; Suppes 1972, p. 129). Finite ordinal numbers are commonly denoted using arabic numerals, while transfinite ordinals as denoted using lower case Greek letters.

It is easy to see that every *finite* TOTALLY ORDERED SET is WELL ORDERED. Any two TOTALLY ORDERED SETS with k elements (for k a nonnegative integer) are ORDER ISOMORPHIC, and therefore have the same ORDER TYPE (which is also an ordinal number). The ordinals for finite sets are denoted 0, 1, 2, 3, ..., i.e., the integers one less than the corresponding nonnegative integers.

The first transfinite ordinal, denoted ω, is the ORDER TYPE of the set of nonnegative integers (Dauben 1979, p 152; Moore 1982, p. viii; Rubin 1967, pp. 86 and 177; Suppes 1972, p. 128). This is the "smallest" of Cantor's TRANSFINITE NUMBERS, defined to be the smallest ordinal number greater than the ordinal number of the WHOLE NUMBERS. Conway and Guy (1996) denote it with the notation $\omega = \{0, 1, \ldots|\}$.

From the definition of ORDINAL COMPARISON, is follows that the ordinal numbers are a WELL ORDERED SET. In order of increasing size, the ordinal numbers are 0, 1, 2, ..., ω, $\omega + 1$, $\omega + 2$, ..., $\omega + \omega$, $\omega + \omega + 1$, ... The notation of ordinal numbers can be a bit counterintuitive, e.g., even though $1 + \omega = \omega$, $\omega + 1 > \omega$. The CARDINALITY of the set of countable ordinal numbers is denoted ALEPH-1.

If $(A, \leq)$ is a WELL ORDERED SET with ordinal number α, then the set of all ordinals $< \alpha$ is ORDER ISOMORPHIC to A. This provides the motivation to define an ordinal as the set of all ordinals less that itself. John von Neumann defined a set α to be an ordinal number IFF

1. If β is a member of α, then β is a PROPER SUBSET of α
2. If β and γ are members of α then one of the following is true: $\beta = \gamma$, β is a member of γ, or γ is a member of β.
3. If B is a nonempty PROPER SUBSET of α, then there exists a γ member of B such that the intersection $\gamma \cap B$ is empty.

(Rubin 1967, p. 176; Ciesielski 1997, p. 44). This is the standard representation of ordinals. In this representation,

symbol	elements	description
0	$\{\}$	empty set
1	$\{0\}$	set of one element
2	$\{0, 1\}$	set of two elements
3	$\{0, 1, 2\}$	set of three elements
$\vdots$		
ω	$\{0, 1, 2, \ldots\}$	set of all finite ordinals
$\omega + 1$	$\{0, 1, 2, \ldots, \omega\}$	
$\vdots$		

ω_1	set of all countable ordinals
$\vdots$	
ω_2	set of all countable and $\aleph_1$ ordinals
$\vdots$	
ω_ω	set all finite ordinals and $\aleph_k$ ordinals for all nonnegative integers k
$\vdots$	

Rubin (1967, p. 272) provides a nice definition of the ω_α ordinals.

Since for any ordinal α, the union $\alpha \cup \alpha$ is a bigger ordinal $\alpha + 1$, there is no largest ordinal, and the class of all ordinals is therefore a PROPER CLASS (as shown by the BURALI-FORTI PARADOX).

Ordinal numbers have some other rather peculiar properties. The sum of two ordinal numbers can take on two different values, the sum of three can take on five values. The first few terms of this sequence are 2, 5, 13, 33, 81, 193, 449, 33^2, $33 \cdot 81$, 81^2, $81 \cdot 193$, 192^2, ... (Conway and Guy 1996, Sloane's A005348). The sum of n ordinals has either $193^a 81^b$ or $33 \cdot 81^a$ possible answers for $n \geq 15$ (Conway and Guy 1996).

$r \times \omega$ is the same as ω, but $\omega \times r$ is equal to $\underbrace{\omega + \ldots + \omega}$. ω^2 is larger than any number OF THE FORM $\omega \times r$, ω^3 is larger than ω^2, and so on.

There exist ordinal numbers which cannot be constructed from smaller ones by finite additions, multiplications, and exponentiations. These ordinals obey CANTOR'S EQUATION. The first such ordinal is

$$\epsilon_0 = \underbrace{\omega^{\omega^{\cdot^{\cdot^{\omega}}}}}_{\omega} = 1 + \omega + \omega^\omega + \omega^{\omega^\omega} + \ldots.$$

The next is

$$\epsilon_1 = (1 + \epsilon_0) + \omega^{\epsilon_0 + 1} + \omega^{\omega\epsilon_0 + 1} + \ldots,$$

then follow ϵ_2, ϵ_3, ..., ϵ_ω, $\epsilon_{\omega+1}$, ..., $\epsilon_{\omega \times 2}$, ..., ϵ_{ω^2}, ϵ_{ω^ω}, ..., ϵ_{ϵ_0}, ϵ_{ϵ_0+1}, ..., $\epsilon_{\epsilon_0+\omega}$, ..., $\epsilon_{\epsilon_0+\omega}$, ..., $\epsilon_{\epsilon_0 \times 2}$, ..., ϵ_{ϵ_1}, ..., ϵ_{ϵ_2}, ..., $\epsilon_{\epsilon_\omega}$, ..., $\epsilon_{\epsilon_{\epsilon_0}}$, ..., $\epsilon_{\epsilon_{\epsilon_1}}$, ..., $\epsilon_{\epsilon_{\epsilon_\omega}}$, ..., $\epsilon_{\epsilon_{\epsilon_{\epsilon_0}}}$, ... (Conway and Guy 1996).

ORDINAL ADDITION, ORDINAL MULTIPLICATION, and ORDINAL EXPONENTIATION can all be defined. Although these definitions also work perfectly well for ORDER TYPES, this does not seem to be commonly done. There are two methods common used to define operations on the ordinals: one is using sets, and the other is inductively.

Ordinary Differential Equation

An ordinary differential equation (frequently abbreviated ODE) is an equality involving a function and its DERIVATIVES. An ODE of order n is an equation OF THE FORM

$$F(x, y, y', \cdots, y^{(n)}) = 0, \tag{1}$$

where $y' = dy/dx$ is a first DERIVATIVE with respect to x and $y^{(n)} = d^n y/dx^n$ is an nth DERIVATIVE with respect to x. An ODE of order n is said to be linear if it is OF THE FORM

$$a_n(x)y^{(n)} + a_{n-1}(x)y^{(n-1)} + \cdots + a_1(x)y' + a_0(x)y = Q(x). \tag{2}$$

A linear ODE where $Q(x) = 0$ is said to be homogeneous. Confusingly, an ODE OF THE FORM

$$\frac{dy}{dx} = f\left(\frac{y}{x}\right) \tag{3}$$

is also sometimes called "homogeneous."

In general, an nth-order ODE has n linearly independent solutions. Furthermore, any LINEAR COMBINATION of LINEARLY INDEPENDENT FUNCTIONS solutions is also a solution.

Simple theories exist for first-order (INTEGRATING FACTOR) and second-order (STURM-LIOUVILLE THEORY) ordinary differential equations, and arbitrary ODEs with linear constant COEFFICIENTS can be solved when they are of certain factorable forms. Integral transforms such as the LAPLACE TRANSFORM can also be used to solve classes of linear ODEs. Morse and Feshbach (1953, pp. 667–674) give canonical forms and solutions for second-order ODEs.

While there are many general techniques for analytically solving classes of ODEs, the only practical solution technique for complicated equations is to use numerical methods (Milne 1970, Jeffreys and Jeffreys 1988). The most popular of these is the RUNGE-KUTTA

METHOD, but many others have been developed, including the COLLOCATION METHOD and GALERKIN METHOD. A vast amount of research and huge numbers of publications have been devoted to the numerical solution of differential equations, both ordinary and PARTIAL (PDEs) as a result of their importance in fields as diverse as physics, engineering, economics, and electronics.

The solutions to an ODE satisfy EXISTENCE and UNIQUENESS properties. These can be formally established by PICARD'S EXISTENCE THEOREM for certain classes of ODEs. Let a system of first-order ODE be given by

$$\frac{dx_i}{dt} = f_i(x_1, \ldots, x_n, t), \tag{4}$$

for $i = 1, ..., n$ and let the functions $f_i(x_1, \ldots, x_n, t)$, where $i = 1, ..., n$, all be defined in a DOMAIN D of the $(n+1)$-D space of the variables $x_1, ..., x_n, t$. Let these functions be continuous in D and have continuous first PARTIAL DERIVATIVES $\partial f_i/\partial x_j$ for $i = 1, ..., n$ and $j = 1, ..., n$ in D. Let $(x_1^0, \ldots, x_n^0)$ be in D. Then there exists a solution of (4) given by

$$x_1 = x_1(t), \ldots, x_n = x_n(t) \tag{5}$$

for $t_0 - \delta < t < t_0 + \delta$ (where $\delta > 0$) satisfying the initial conditions

$$x_1(t_0) = x_1^0, \ldots, x_n(t_0) = x_n^0. \tag{6}$$

Furthermore, the solution is unique, so that if

$$x_1 = x_1{}^*(t), \ldots, x_n = x_n{}^*(t) \tag{7}$$

is a second solution of (4) for $t_0 - \delta < t < t_0 + \delta$ satisfying (6), then $x_i(t) \equiv x_i{}^*(t)$ for $t_0 - \delta < t < t_0 + \delta$. Because every nth-order ODE can be expressed as a system of n first-order differential equations, this theorem also applies to the single nth-order ODE.

An exact FIRST-ORDER ODES is one OF THE FORM

$$p(x, y)\, dx + q(x, y)\, dy = 0, \tag{8}$$

where

$$\frac{\partial p}{\partial y} = \frac{\partial q}{\partial x}. \tag{9}$$

An equation OF THE FORM (8) with

$$\frac{\partial p}{\partial y} \neq \frac{\partial q}{\partial x} \tag{10}$$

is said to be nonexact. If

$$\frac{\frac{\partial p}{\partial y} - \frac{\partial q}{\partial x}}{q} = f(x) \tag{11}$$

in (8), it has an x-dependent integrating factor. If

$$\frac{\frac{\partial q}{\partial x} - \frac{\partial p}{\partial y}}{xp - yq} = f(xy) \tag{12}$$

in (8), it has an xy-dependent integrating factor. If

$$\frac{\frac{\partial q}{\partial x} - \frac{\partial p}{\partial y}}{p} = f(y) \tag{13}$$

in (8), it has a y-dependent integrating factor.

Other special first-order types include cross multiple equations

$$yf(xy)\, dx + xg(xy)\, dy = 0, \tag{14}$$

homogeneous equations

$$\frac{dy}{dx} = f\left(\frac{y}{x}\right), \tag{15}$$

linear equations

$$\frac{dy}{dx} + p(x)y = q(x), \tag{16}$$

and separable equations

$$\frac{dy}{dx} = X(x)Y(y). \tag{17}$$

Special classes of SECOND-ORDER ODES include

$$\frac{d^2y}{dx^2} = f(y, y') \tag{18}$$

(x missing) and

$$\frac{d^2y}{dx^2} = f(x, y') \tag{19}$$

(y missing). A second-order linear homogeneous ODE

$$\frac{d^2y}{dx^2} + P(x)\frac{dy}{dx} + Q(x)y = 0 \tag{20}$$

for which

$$\frac{Q'(x) + 2P(x)Q(x)}{2[Q(x)]^{3/2}} = [\text{constant}] \tag{21}$$

can be transformed to one with constant coefficients.

The undamped equation of SIMPLE HARMONIC MOTION is

$$\frac{d^2y}{dx^2} + \omega_0^2 y = 0, \tag{22}$$

which becomes

$$\frac{d^2y}{dx^2} + \beta\, \frac{dy}{dx} + \omega_0^2 y = 0 \tag{23}$$

when damped, and

$$\frac{d^2y}{dx^2}+\beta\frac{dy}{dx}+\omega_0^2y=A\cos(\omega t) \qquad (24)$$

when both forced and damped.

SYSTEMS WITH CONSTANT COEFFICIENTS are of the form

$$\frac{d\mathbf{x}}{dt}=\mathsf{A}\mathbf{x}(t)+\mathbf{p}(t). \qquad (25)$$

The following are examples of important ordinary differential equations which commonly arise in problems of mathematical physics.

ABEL'S DIFFERENTIAL EQUATION

$$y'=f_0(x)+f_1(x)y+f_2(x)y^2+f_3(x)y^3+\ldots \qquad (26)$$

$$[g_0(x)+g_1(x)y]y'=f_0(x)+f_1(x)y+f_2(x)y^2+f_3(x)y^3. \qquad (27)$$

AIRY DIFFERENTIAL EQUATION

$$\frac{d^2y}{dx^2}-xy=0. \qquad (28)$$

ANGER DIFFERENTIAL EQUATION

$$y''+\frac{y'}{x}+\left(1-\frac{\nu^2}{x^2}\right)y=\frac{x-\nu}{\pi x^2}\sin(\nu x). \qquad (29)$$

BAER DIFFERENTIAL EQUATIONS

$$(x-a_1)(x-a_2)y''+\tfrac{1}{2}[2x-(a_1+a_2)]y'-\left(p^2x+q^2\right)y =0, \qquad (30)$$

$$(x-a_1)(x-a_2)y''+\tfrac{1}{2}[2x-(a_1+a_2)]y' -\left(k^2x^2-p^2x+q^2\right)y=0. \qquad (31)$$

BERNOULLI DIFFERENTIAL EQUATION

$$\frac{dy}{dx}+p(x)y=q(x)y^n. \qquad (32)$$

BESSEL DIFFERENTIAL EQUATION

$$x^2\frac{d^2y}{dx^2}+x\frac{dy}{dx}+\left(\lambda^2x^2-n^2\right)y=0. \qquad (33)$$

BINOMIAL DIFFERENTIAL EQUATION

$$(y')^m=f(x,\ y). \qquad (34)$$

BÔCHER EQUATION

$$y''+\tfrac{1}{2}\left[\frac{m_1}{x-a_1}+\ldots+\frac{m_{n-1}}{x-a_{n-1}}\right]y' +\tfrac{1}{4}\left[\frac{A_0+A_1x+\ldots+A_lx^l}{(x-a_1)^{m_1}(x-a_2)^{m_2}\cdots(x-a_{n-1})^{m_{n-1}}}\right]y=0. \qquad (35)$$

BRIOT-BOUQUET EQUATION

$$x^m\frac{dy}{dx}=f(x,\ y). \qquad (36)$$

CHEBYSHEV DIFFERENTIAL EQUATION

$$\left(1-x^2\right)\frac{d^2y}{dx^2}-x\frac{dy}{dx}+\alpha^2y=0. \qquad (37)$$

CLAIRAUT'S DIFFERENTIAL EQUATION

$$y=x\frac{dy}{dx}+f\left(\frac{dy}{dx}\right). \qquad (38)$$

CONFLUENT HYPERGEOMETRIC DIFFERENTIAL EQUATION

$$x\frac{d^2y}{dx^2}+(c-x)\frac{dy}{dx}-ay=0. \qquad (39)$$

D'ALEMBERT'S EQUATION.

$$y=xf(y')+g(y'). \qquad (40)$$

DUFFING DIFFERENTIAL EQUATION

$$\ddot{x}+\omega_0^2x+\beta x^3=0. \qquad (41)$$

ECKART DIFFERENTIAL EQUATION

$$y''+\left[\frac{\alpha\eta}{1+\eta}+\frac{\beta\eta}{(1+n)^2}+\gamma\right]y=0, \qquad (42)$$

where $\eta=e^{\delta x}$.

EMDEN-FOWLER DIFFERENTIAL EQUATION

$$(x^py')'\pm x^\sigma y^n=0. \qquad (43)$$

EULER DIFFERENTIAL EQUATION

$$x^2\frac{d^2y}{dx^2}+ax\frac{dy}{dx}+by=S(x). \qquad (44)$$

HALM'S DIFFERENTIAL EQUATION

$$\left(1+x^2\right)^2+y''+\lambda y=0. \qquad (45)$$

HERMITE DIFFERENTIAL EQUATION

$$\frac{d^2y}{dx^2}-2x\frac{dy}{dx}+\lambda y=0. \qquad (46)$$

HEUN'S DIFFERENTIAL EQUATION

$$\frac{d^2w}{dx^2}+\left(\frac{\gamma}{x}+\frac{\delta}{x-1}+\frac{\varepsilon}{x-a}\right)\frac{dw}{dx}+\frac{\alpha\beta x-q}{x(x-1)(x-a)}w =0. \qquad (47)$$

HILL'S DIFFERENTIAL EQUATION

$$\frac{d^2y}{dx^2}\left[\theta_0+2\sum_{n=1}^{\infty}\theta_n\cos(2nz)\right]=0. \qquad (48)$$

HYPERGEOMETRIC DIFFERENTIAL EQUATION

$$x(x-1)\frac{d^2y}{dx^2}+[(1+\alpha+\beta)x-\gamma]\frac{dy}{dx}+\alpha\beta y=0. \tag{49}$$

JACOBI DIFFERENTIAL EQUATION

$$(1-x^2)y''+[\beta-\alpha-(\alpha+\beta+2)x]y'+n(n+\alpha+\beta+1)y =0. \tag{50}$$

LAGUERRE DIFFERENTIAL EQUATION

$$x\frac{d^2y}{dx^2}+(1-x)\frac{dy}{dx}+\lambda y=0. \tag{51}$$

LAMÉ'S DIFFERENTIAL EQUATION

$$(x^2-b^2)(x^2-c^2)\frac{d^2z}{dx^2}+x(x^2-b^2+x^2-c^2)\frac{dz}{dx} -[m(m+1)x^2-(b^2+c^2)p]z=0. \tag{52}$$

LANE-EMDEN DIFFERENTIAL EQUATION

$$\frac{1}{\xi^2}\frac{d}{d\xi}\left(\xi^2\frac{d\theta}{d\xi}\right)+\theta^n=0. \tag{53}$$

LEGENDRE DIFFERENTIAL EQUATION

$$(1-x^2)\frac{d^2y}{dx^2}-2x\frac{dy}{dx}+\alpha(\alpha+1)y=0. \tag{54}$$

LINEAR CONSTANT COEFFICIENTS

$$a_0\frac{d^ny}{dx^n}+\ldots+a_{n-1}\frac{dy}{dx}+a_ny=p(x). \tag{55}$$

LOMMEL DIFFERENTIAL EQUATION

$$z^2\frac{d^2y}{dz^2}+z\frac{dy}{dz}-(z^2+\nu^2)y=kz^{\mu+1}. \tag{56}$$

LÖWNER'S DIFFERENTIAL EQUATION

$$y'=-y\frac{1+\kappa(x)y}{1-\kappa(x)y}.$$

MALMSTÉN'S DIFFERENTIAL EQUATION

$$\frac{d^2y}{dx^2}+\frac{r}{z}\frac{dy}{dx}=\left(Az^m+\frac{s}{z^2}\right)y. \tag{57}$$

MATHIEU DIFFERENTIAL EQUATION

$$\frac{d^2V}{dv^2}+[a-2q\cos(2v)]V=0. \tag{58}$$

MODIFIED BESSEL DIFFERENTIAL EQUATION

$$x^2\frac{d^2y}{dx^2}+x\frac{dy}{dx}-(x^2+n^2)y=0. \tag{59}$$

MODIFIED SPHERICAL BESSEL DIFFERENTIAL EQUATION

$$r^2\frac{d^2R}{dr^2}+2r\frac{dR}{dr}-\left[k^2r^2+n(n+1)\right]R=0. \tag{60}$$

RAYLEIGH DIFFERENTIAL EQUATION

$$y''-\mu\left(1-\tfrac{1}{3}y'^2\right)y'+y=0. \tag{61}$$

RICCATI DIFFERENTIAL EQUATION

$$\frac{dw}{dx}=q_0(x)+q_1(x)w+q_2(x)w^2. \tag{62}$$

RIEMANN P-DIFFERENTIAL EQUATION

$$\frac{d^2u}{dz^2}+\left[\frac{1-\alpha-\alpha'}{z-a}+\frac{1-\beta-\beta'}{z-b}+\frac{1-\gamma-\gamma'}{z-c}\right]\frac{du}{dz} +\left[\frac{\alpha\alpha'(a-b)(a-c)}{z-a}+\frac{\beta\beta'(b-c)(b-a)}{z-b}+\frac{\gamma\gamma'(c-a)(c-b)}{z-c}\right] \times\frac{u}{(z-a)(z-b)(z-c)}=0. \tag{63}$$

SHARPE'S DIFFERENTIAL EQUATION

$$zy''+y'+(z+A)y=0. \tag{64}$$

SPHERICAL BESSEL DIFFERENTIAL EQUATION

$$r^2\frac{d^2R}{dr^2}+2r\frac{dR}{dr}+\left[k^2r^2-n(n+1)\right]R=0. \tag{65}$$

STRUVE DIFFERENTIAL EQUATION

$$z^2y''+zy'+(z^2-\nu^2)y=\frac{4\left(\frac{1}{2}z\right)^{\nu+1}}{\sqrt{\pi}\,\Gamma\left(\nu+\frac{1}{2}\right)}. \tag{66}$$

STURM-LIOUVILLE EQUATION

$$\frac{d}{dx}\left[p(x)\frac{dy}{dx}\right]+[\lambda w(x)-q(x)]y=0. \tag{67}$$

ULTRASPHERICAL DIFFERENTIAL EQUATION

$$(1-x^2)y''-(2\alpha+1)xy'+n(n+2\alpha)y=0. \tag{68}$$

VAN DER POL EQUATION

$$y''-\mu(1-y^2)y'+y=0. \tag{69}$$

WEBER DIFFERENTIAL EQUATION

$$\frac{d^2y}{dz^2}+\left(n+\tfrac{1}{2}-\tfrac{1}{4}z^2\right)y=0. \tag{70}$$

WHITTAKER DIFFERENTIAL EQUATION

$$\frac{d^2u}{dz^2}+\frac{du}{dz}+\left(\frac{k}{z}+\frac{\frac{1}{4}-m^2}{z^2}\right)u=0. \qquad (71)$$

Ordinary Differential Equation—First-Order

Given a first-order ORDINARY DIFFERENTIAL EQUATION

$$\frac{dy}{dx}=F(x,\ y), \qquad (1)$$

if $F(x,\ y)$ can be expressed using SEPARATION OF VARIABLES as

$$F(x,\ y)=X(x)Y(y), \qquad (2)$$

then the equation can be expressed as

$$\frac{dy}{Y(y)}=X(x)\ dx \qquad (3)$$

and the equation can be solved by integrating both sides to obtain

$$\int\frac{dy}{Y(y)}=\int X(x)\ dx. \qquad (4)$$

Any first-order ODE OF THE FORM

$$\frac{dy}{dx}+p(x)y=q(x) \qquad (5)$$

can be solved by finding an INTEGRATING FACTOR $\mu=\mu(x)$ such that

$$\frac{d}{dx}(\mu y)=\mu\ \frac{dy}{dx}+y\ \frac{d\mu}{dx}=\mu q(x). \qquad (6)$$

Dividing through by μy yields

$$\frac{1}{y}\ \frac{dy}{dx}+\frac{1}{\mu}\ \frac{d\mu}{dx}=\frac{q(x)}{y}. \qquad (7)$$

However, this condition enables us to explicitly determine the appropriate μ for arbitrary p and q. To accomplish this, take

$$p(x)=\frac{1}{\mu}\ \frac{d\mu}{dx} \qquad (8)$$

in the above equation, from which we recover the original equation (5), as required, in the form

$$\frac{1}{y}\ \frac{dy}{dx}+p(x)=\frac{q(x)}{y}. \qquad (9)$$

But we can integrate both sides of (8) to obtain

$$\int p(x)\,dx = \int \frac{d\mu}{\mu} = \ln \mu + c \tag{10}$$

$$\mu = e^{\int p(x)\,dx}. \tag{11}$$

Now integrating both sides of (6) gives

$$\mu y = \int \mu q(x)\,dx + c \tag{12}$$

(with μ now a known function), which can be solved for y to obtain

$$y = \frac{\int \mu q(x)\,dx + c}{\mu} = \frac{\int e^{\int^x p(x')\,dx'} q(x)\,d(x) + c}{e^{\int^x p(x')\,dx'}}, \tag{13}$$

where c is an arbitrary constant of integration.

Given an nth-order linear ODE with constant COEFFICIENTS

$$\frac{d^n y}{dx^n} + a_{n-1}\frac{d^{n-1}y}{dx^{n-1}} + \ldots a_1 \frac{dy}{dx} + a_0 y = Q(x), \tag{14}$$

first solve the characteristic equation obtained by writing

$$y \equiv e^{rx} \tag{15}$$

and setting $Q(x) = 0$ to obtain the n COMPLEX ROOTS.

$$r^n e^{rx} + a_{n-1} r^{n-1} e^{rx} + \ldots + a_1 r e^{rx} + a_0 e^{rx} = 0 \tag{16}$$

$$r^n + a_{n-1} r^{n-1} + \ldots + a_1 r + a_0 = 0. \tag{17}$$

Factoring gives the ROOTS r_i,

$$(r - r_1)(r - r_2)\cdots(r - r_n) = 0. \tag{18}$$

For a nonrepeated REAL ROOT r, the corresponding solution is

$$y = e^{rx}. \tag{19}$$

If a REAL ROOT r is repeated k times, the solutions are degenerate and the linearly independent solutions are

$$y = e^{rx}, y = xe^{rx}, \cdots, y = x^{k-1}e^{rx}. \tag{20}$$

Complex ROOTS always come in COMPLEX CONJUGATE pairs, $r_\pm = a \pm ib$. For nonrepeated COMPLEX ROOTS, the solutions are

$$y = e^{ax}\cos(bx), y = e^{ax}\sin(bx). \tag{21}$$

If the COMPLEX ROOTS are repeated k times, the linearly independent solutions are

$$y = e^{ax}\cos(bx), y = e^{ax}\sin(bx), \cdots,$$

$$y = x^{k-1}e^{ax}\cos(bx), y = x^{k-1}e^{ax}\sin(bx). \tag{22}$$

Linearly combining solutions of the appropriate types with arbitrary multiplicative constants then gives the complete solution. If initial conditions are specified, the constants can be explicitly determined. For example, consider the sixth-order linear ODE

$$(\tilde{D} - 1)(\tilde{D} - 2)^3(\tilde{D}^2 + \tilde{D} + 1)y = 0, \tag{23}$$

which has the characteristic equation

$$(r - 1)(r - 2)^3(r^2 + r + 1) = 0. \tag{24}$$

The roots are 1, 2 (three times), and $(-1 \pm \sqrt{3}i)/2$, so the solution is

$$y = Ae^x + Be^{2x} + Cxe^{2x} + Dx^2e^{3x} + Ee^{-x/2}\cos\left(\tfrac{1}{2}\sqrt{3}x\right)$$

$$+Fe^{-x}\sin\left(\tfrac{1}{2}\sqrt{3}x\right). \tag{25}$$

If the original equation is nonhomogeneous ($Q(x) \neq 0$), now find the particular solution y^* by the method of VARIATION OF PARAMETERS. The general solution is then

$$y(x) = \sum_{i=1}^{n} c_i y_i(x) + y^*(x), \tag{26}$$

where the solutions to the linear equations are $y_1(x)$, $y_2(x)$, ..., $y_n(x)$, and $y^*(x)$ is the particular solution.

Ordinary Differential Equation—First-Order Exact

Consider a first-order ODE in the slightly different form

$$p(x, y)\,dx + q(x, y)\,dy = 0. \tag{1}$$

Such an equation is said to be exact if

$$\frac{\partial p}{\partial y} = \frac{\partial q}{\partial x}. \tag{2}$$

This statement is equivalent to the requirement that a CONSERVATIVE FIELD exists, so that a scalar potential can be defined. For an exact equation, the solution is

$$\int_{(x_0, y_0)}^{(x, y)} p(x, y)\,dx + q(x, y)\,dy = c, \tag{3}$$

where c is a constant.

A first-order ODE (1) is said to be inexact if

$$\frac{\partial p}{\partial y} \neq \frac{\partial q}{\partial x}. \tag{4}$$

For a nonexact equation, the solution may be ob-

tained by defining an INTEGRATING FACTOR μ of (6) so that the new equation

$$\mu p(x, y)\, dx + \mu q(x, y)\, dy = 0 \tag{5}$$

satisfies

$$\frac{\partial}{\partial y}(\mu p) = \frac{\partial}{\partial x}(\mu q), \tag{6}$$

or, written out explicitly,

$$p\, \frac{\partial \mu}{\partial y} + \mu\, \frac{\partial p}{\partial y} = q\, \frac{\partial \mu}{\partial x} + \mu\, \frac{\partial p}{\partial x}. \tag{7}$$

This transforms the nonexact equation into an exact one. Solving (7) for μ gives

$$\mu = \frac{q\, \frac{\partial \mu}{\partial x} - p\, \frac{\partial \mu}{\partial y}}{\frac{\partial p}{\partial y} - \frac{\partial q}{\partial x}}. \tag{8}$$

Therefore, if a function μ satisfying (8) can be found, then writing

$$P(x, y) = \mu p \tag{9}$$

$$Q(x, y) = \mu q \tag{10}$$

in equation (5) then gives

$$P(x, y)\, dx + Q(x, y)\, dy = 0, \tag{11}$$

which is then an exact ODE. Special cases in which μ can be found include x-dependent, xy-dependent, and y-dependent integrating factors.

Given an inexact first-order ODE, we can also look for an INTEGRATING FACTOR $\mu(x)$ so that

$$\frac{\partial \mu}{\partial y} = 0. \tag{12}$$

For the equation to be exact in μp and μq, the equation for a first-order nonexact ODE

$$p\, \frac{\partial \mu}{\partial y} + \mu\, \frac{\partial p}{\partial y} = q\, \frac{\partial \mu}{\partial x} + \mu\, \frac{\partial p}{\partial x} \tag{13}$$

becomes

$$\mu\, \frac{\partial p}{\partial y} = q\, \frac{\partial \mu}{\partial x} + \mu\, \frac{\partial p}{\partial x}. \tag{14}$$

Solving for $\partial \mu/\partial x$ gives

$$\frac{\partial \mu}{\partial x} = \mu(x) \frac{\frac{\partial p}{\partial y} - \frac{\partial q}{\partial x}}{q} \equiv f(x, y)\mu(x), \tag{15}$$

which will be integrable if

$$f(x, y) \equiv \frac{\frac{\partial p}{\partial y} - \frac{\partial q}{\partial x}}{q} = f(x), \tag{16}$$

in which case

$$\frac{d\mu}{\mu} = f(x)\, dx, \tag{17}$$

so that the equation is integrable

$$\mu(x) = e^{\int f(x)\, dx}, \tag{18}$$

and the equation

$$[\mu p(x, y)]\, dx + [\mu q(x, y)]\, dy = 0 \tag{19}$$

with known $\mu(x)$ is now exact and can be solved as an exact ODE.

Given in an exact first-order ODE, look for an INTEGRATING FACTOR $\mu(x, y) = g(xy)$. Then

$$\frac{\partial \mu}{\partial x} = \frac{\partial g}{\partial x}\, y. \tag{20}$$

$$\frac{\partial \mu}{\partial y} = \frac{\partial g}{\partial y}\, x. \tag{21}$$

Combining these two,

$$\frac{\partial \mu}{\partial x} = \frac{y}{x}\, \frac{\partial \mu}{\partial y}. \tag{22}$$

For the equation to be exact in μp and μq, the equation for a first-order nonexact ODE

$$p\, \frac{\partial \mu}{\partial y} + \mu\, \frac{\partial p}{\partial y} = q\, \frac{\partial \mu}{\partial x} + \mu\, \frac{\partial p}{\partial x} \tag{23}$$

becomes

$$\frac{\partial \mu}{\partial y}\left(p - \frac{y}{x}\, q\right) = \left(\frac{\partial p}{\partial x} - \frac{\partial p}{\partial y}\right)\mu. \tag{24}$$

Therefore,

$$\frac{1}{x}\, \frac{\partial \mu}{\partial y} = \frac{\frac{\partial q}{\partial x} - \frac{\partial p}{\partial y}}{xp - yq}\, \mu. \tag{25}$$

Define a new variable

$$t(x, y) \equiv xy, \tag{26}$$

then $\partial t/\partial y = x$, so

$$\frac{\partial \mu}{\partial t} = \frac{\partial \mu}{\partial y}\, \frac{\partial y}{\partial t} = \frac{\frac{\partial q}{\partial x} - \frac{\partial p}{\partial y}}{xp - yq}\, \mu(t) \equiv f(x, y)\mu(t). \tag{27}$$

Now, if

$$f(x,\ y) \equiv \frac{\dfrac{\partial q}{\partial x} - \dfrac{\partial p}{\partial y}}{xp - yq} = f(xy) = f(t), \tag{28}$$

then

$$\frac{\partial \mu}{\partial t} = f(t)\mu(t), \tag{29}$$

so that

$$\mu = e^{\int f(t)\, dt} \tag{30}$$

and the equation

$$[\mu p(x,\ y)]\ dx + [\mu q(x,\ y)]\ dy = 0 \tag{31}$$

is now exact and can be solved as an exact ODE.

Given an inexact first-order ODE, assume there exists an integrating factor

$$\mu = f(y), \tag{32}$$

so $\partial \mu / \partial x = 0$. For the equation to be exact in μp and μq, equation (7) becomes

$$\frac{\partial \mu}{\partial y} = \frac{\dfrac{\partial q}{\partial x} - \dfrac{\partial p}{\partial y}}{p}\ \mu = f(x,\ y)\mu(y). \tag{33}$$

Now, if

$$f(x,\ y) \equiv \frac{\dfrac{\partial q}{\partial x} - \dfrac{\partial p}{\partial y}}{p} = f(y), \tag{34}$$

then

$$\frac{d\mu}{\mu} = f(y)\ dy, \tag{35}$$

so that

$$\mu(y) = e^{\int f(y)\, dy}, \tag{36}$$

and the equation

$$\mu p(x,\ y)\ dx + \mu q(x,\ y)\ dy = 0 \tag{37}$$

is now exact and can be solved as an exact ODE.

Given a first-order ODE OF THE FORM

$$yf(xy)\ dx + xg(xy)\ dy = 0, \tag{38}$$

define

$$v \equiv xy. \tag{39}$$

Then the solution is

$$\begin{cases} \ln x = \displaystyle\int \frac{g(v)\ dv}{c[g(v) - f(v)]} + c & \text{for} \quad g(v) \neq f(v) \\ xy = c & \text{for} \quad g(v) = f(v). \end{cases} \tag{40}$$

If

$$\frac{dy}{dx} = F(x,\ y) = G(v), \tag{41}$$

where

$$v \equiv \frac{y}{x}, \tag{42}$$

then letting

$$y \equiv xv \tag{43}$$

gives

$$\frac{dy}{dx} = x\ dv/dx + v \tag{44}$$

$$x\ \frac{dv}{dx} + v = G(v). \tag{45}$$

This can be integrated by quadratures, so

$$\ln x = \int \frac{dv}{f(v) - v} + c \quad \text{for}\ f(v) \neq v \tag{46}$$

$$y = cx \quad \text{for}\ f(v) = v. \tag{47}$$

Ordinary Differential Equation—Second-Order

An ODE

$$y'' + P(x)y' + Q(x)y = 0 \tag{1}$$

has singularities for finite $x = x_0$ under the following conditions: (a) If either $P(x)$ or $Q(x)$ diverges as $x \to x_0$, but $(x - x_0)P(x)$ and $(x - x_0)^2 Q(x)$ remain finite as $x \to x_0$, then x_0 is called a regular or nonessential singular point. (b) If $P(x)$ diverges faster than $(x - x_0)^{-1}$ so that $(x - x_0)P(x) \to \infty$ as $x \to x_0$, or $Q(x)$ diverges faster than $(x - x_0)^{-2}$ so that $(x - x_0)^2 Q(x) \to \infty$ as $x \to x_0$, then x_0 is called an irregular or essential singularity.

Singularities of equation (1) at infinity are investigated by making the substitution $x \equiv z^{-1}$, so $dx = -z^{-2} dz$, giving

$$\frac{dy}{dx} = -z^2\ \frac{dy}{dz} \tag{2}$$

$$\frac{d^2y}{dx^2} = -z^2\ \frac{d}{dz}\left(-z^2\ \frac{dy}{dz}\right) = -z^2\left(-2z\ \frac{dy}{dz} - z^2\ \frac{d^2y}{dz^2}\right)$$

$$= 2z^3\ \frac{dy}{dz} + z^4\ \frac{d^2y}{dz^2}. \tag{3}$$

Then (1) becomes

$$z^4 \frac{d^2y}{dz^2} + \left[2z^3 - z^2 P(z)\right] \frac{dy}{dz} + Q(z)y = 0. \tag{4}$$

Case (a): If

$$\alpha(z) \equiv \frac{2z - P(z)}{z^2} \tag{5}$$

$$\beta(z) \equiv \frac{Q(z)}{z^4} \tag{6}$$

remain finite at $x = \pm\infty$ ($y = 0$), then the point is ordinary. Case (b): If either $\alpha(z)$ diverges no more rapidly than $1/z$ or $\beta(z)$ diverges no more rapidly than $1/z^2$, then the point is a regular singular point. Case (c): Otherwise, the point is an irregular singular point.

Morse and Feshbach (1953, pp. 667–674) give the canonical forms and solutions for second-order ODEs classified by types of singular points.

For special classes of second-order linear ordinary differential equations, variable COEFFICIENTS can be transformed into constant COEFFICIENTS. Given a second-order linear ODE with variable COEFFICIENTS

$$\frac{d^2y}{dx^2} + p(x)\frac{dy}{dx} = q(x)y = 0. \tag{7}$$

Define a function $z \equiv y(x)$,

$$\frac{dy}{dx} = \frac{dz}{dx}\frac{dy}{dz} \tag{8}$$

$$\frac{d^2y}{dx^2} = \left(\frac{dz}{dx}\right)^2 \frac{d^2y}{dz^2} + \frac{d^2z}{dx^2}\frac{dy}{dz} \tag{9}$$

$$\left(\frac{dz}{dx}\right)^2 \frac{d^2y}{dz^2} + \left[\frac{d^2z}{dx^2} + p(x)\frac{dz}{dx}\right]\frac{dy}{dz} + q(x)y = 0 \tag{10}$$

$$\frac{d^2y}{dz^2} + \left[\frac{\frac{d^2z}{dx^2} + P(x)\frac{dz}{dx}}{\left(\frac{dz}{dx}\right)^2}\right]\frac{dy}{dz} + \left[\frac{q(x)}{\left(\frac{dz}{dx}\right)^2}\right]y$$
$$\equiv \frac{d^2y}{dz^2} + A\frac{dy}{dz} + By = 0. \tag{11}$$

This will have constant COEFFICIENTS if A and B are not functions of x. But we are free to set B to an arbitrary POSITIVE constant for $q(x) \geq 0$ by defining z as

$$z \equiv B^{-1/2} \int [q(x)]^{1/2}\, dx. \tag{12}$$

Then

$$\frac{dz}{dx} = B^{-1/2}[q(x)]^{1/2} \tag{13}$$

$$\frac{d^2z}{dx^2} = \tfrac{1}{2}B^{-1/2}[q(x)]^{-1/2}q'(x), \tag{14}$$

and

$$A = \frac{\frac{1}{2}B^{-1/2}[q(x)]^{-1/2}q'(x) + B^{-1/2}p(x)[q(x)]^{1/2}}{B^{-1}q(x)}$$
$$= \frac{q'(x) + 2p(x)q(x)}{2[q(x)]^{3/2}} B^{1/2}. \tag{15}$$

Equation (11) therefore becomes

$$\frac{d^2y}{dz^2} + \frac{q'(x) + 2p(x)q(x)}{2[q(x)]^{3/2}} B^{1/2} \frac{dy}{dz} + By = 0, \tag{16}$$

which has constant COEFFICIENTS provided that

$$A \equiv \frac{q'(x) + 2p(x)q(x)}{2[q(x)]^{3/2}} B^{1/2} = [\text{constant}]. \tag{17}$$

Eliminating constants, this gives

$$A' \equiv \frac{q'(x) + 2p(x)q(x)}{2[q(x)]^{3/2}} = [\text{constant}]. \tag{18}$$

So for an ordinary differential equation in which A' is a constant, the solution is given by solving the second-order linear ODE with constant COEFFICIENTS

$$\frac{d^2y}{dz^2} + A\frac{dy}{dz} + By = 0 \tag{19}$$

for z, where z is defined as above.

A linear second-order homogeneous differential equation of the general form

$$y'' + P(x)y' + Q(x)y = 0 \tag{20}$$

can be transformed into standard form

$$z'' + q(x)z = 0 \tag{21}$$

with the first-order term eliminated using the substitution

$$\ln y \equiv \ln z - \tfrac{1}{2}\int P(x)dx. \tag{22}$$

Then

$$\frac{y'}{y} = \frac{z'}{z} - \tfrac{1}{2}P(x) \tag{23}$$

$$\frac{yy'' - y'^2}{y^2} = \frac{zz'' - z'^2}{z^2} - \tfrac{1}{2}P'(x) \tag{24}$$

$$\frac{y''}{y} - \left(\frac{y'}{y}\right)^2 = \frac{z''}{z} - \frac{z'^2}{z} - \frac{z'^2}{z^2} - \tfrac{1}{2}P'(x) \tag{25}$$

$$\frac{y''}{y}-\left[\frac{z'}{z}-\tfrac{1}{2}P(x)\right]^2+\frac{z''}{z}-\frac{z'^2}{z}-\tfrac{1}{2}P'(x)$$
$$=\frac{z'^2}{z^2}-\frac{z'}{z}P(x)+\tfrac{1}{4}P^2(x)+\frac{z''}{z}-\frac{z'^2}{z^2}-\tfrac{1}{2}P'(x), \tag{26}$$

so

$$\frac{y''}{y}+P(x)\frac{y'}{y}+Q(x)$$
$$=-\frac{z'}{z}P(x)+\tfrac{1}{4}P^2(x)+\frac{z''}{z}-\tfrac{1}{2}P'(x)+P(x)\left[\frac{z'}{z}-\tfrac{1}{2}P(x)\right]$$
$$+Q(x). \tag{27}$$

Therefore,

$$z''+\left[Q(x)-\tfrac{1}{2}P'(x)-\tfrac{1}{4}P^2(x)\right]z\equiv z''(x)+q(x)z=0, \tag{28}$$

where

$$q(x)\equiv Q(x)-\tfrac{1}{2}P'(x)-\tfrac{1}{4}P^2(x). \tag{29}$$

If $Q(x)=0$, then the differential equation becomes

$$y''+P(x)y'=0, \tag{30}$$

which can be solved by multiplying by

$$\exp\left[\int^x P(x')\,dx'\right] \tag{31}$$

to obtain

$$0=\frac{d}{dx}\left\{\exp\left[\int^x P(x')\,dx'\right]\frac{dy}{dx}\right\} \tag{32}$$

$$c_1=\exp\left[\int^x P(x')\,dx'\right]\frac{dy}{dx} \tag{33}$$

$$y=c_1\int^x\frac{dx}{\exp\left[\int^x P(x')\,dx'\right]}+c_2. \tag{34}$$

If one solution (y_1) to a second-order ODE is known, the other (y_2) may be found using the REDUCTION OF ORDER method. From ABEL'S DIFFERENTIAL EQUATION IDENTITY

$$\frac{dW}{W}=-P(x)\,dx, \tag{35}$$

where

$$W\equiv y_1y_2'-y_1'y_2 \tag{36}$$

$$\int_a^x\frac{dW}{W}=\int_a^x P'(x')\,dx' \tag{37}$$

$$\ln\left[\frac{W(x)}{W(a)}\right]=\int_a^x P(x')\,dx' \tag{38}$$

$$W(x)=W(a)\exp\left[-\int_a^x P(x')\,dx'\right]. \tag{39}$$

But

$$W\equiv y_1y_2'-y_1'y_2=y_1^2\frac{d}{dx}\left(\frac{y_2}{y_1}\right). \tag{40}$$

Combining (39) and (40) yields

$$\frac{d}{dx}\left(\frac{y_2}{y_1}\right)=W(a)\frac{\exp\left[-\int_a^x P(x')\,dx'\right]}{y_1^2} \tag{41}$$

$$y_2(x)=y_1(x)W(a)\int_b^x\frac{\exp\left[-\int_a^{x'} P(x'')dx''\right]}{[y_1(x')]^2}\,dx'. \tag{42}$$

Disregarding $W(a)$, since it is simply a multiplicative constant, and the constants a and b, which will contribute a solution which is not linearly independent of (y_1),

$$y_2(x)=y_1(x)\int^x\frac{\exp\left[-\int^{x'} P(x'')\,dx''\right]}{[y_1(x')]^2}\,dx'. \tag{43}$$

If $P(x)=0$, this simplifies to

$$y_2(x)=y_1(x)\int^x\frac{dx'}{[y_1(x')]^2}. \tag{44}$$

For a nonhomogeneous second-order ODE in which the x term does not appear in the function $f(x,\ y,\ y')$,

$$\frac{d^2y}{dx^2}=f(y,\ y') \tag{45}$$

let $v\equiv y'$, then

$$\frac{dv}{dx}=f(v,\ y)=\frac{dv}{dy}\frac{dy}{dx}=v\frac{dv}{dy}. \tag{46}$$

So the first-order ODE

$$v\frac{dv}{dy}=f(y,\ v), \tag{47}$$

if linear, can be solved for v as a linear first-order ODE. Once the solution is known,

$$\frac{dy}{dx}=v(y) \tag{48}$$

$$\int\frac{dy}{v(y)}=\int dx. \tag{49}$$

On the other hand, if y is missing from $f(x,\ y,\ y')$,

$$\frac{d^2y}{dx^2}=f(x,y'), \tag{50}$$

let $v \equiv y'$, then $v' = y''$, and the equation reduces to

$$v' = f(x, v), \tag{51}$$

which, if linear, can be solved for v as a linear first-order ODE. Once the solution is known,

$$y = \int v(x)\, dx. \tag{52}$$

Ordinary Differential Equation—System with Constant Coefficients

To solve the system of differential equations

$$\frac{d\mathbf{x}}{dt} = \mathsf{A}\mathbf{x}(\mathrm{t}) + \mathbf{p}(\mathrm{t}), \tag{1}$$

where A is a MATRIX and $\mathbf{x}$ and $\mathbf{p}$ are VECTORS, first consider the homogeneous case with $\mathbf{p} = 0$. Then the solutions to

$$\frac{d\mathbf{x}}{dt} = \mathbf{a}\mathbf{x}(t) \tag{2}$$

are given by

$$\mathbf{x}(t) = e^{\mathbf{a}t}\mathbf{x}(\mathbf{t}). \tag{3}$$

But, by the MATRIX DECOMPOSITION THEOREM, the MATRIX EXPONENTIAL can be written as

$$e^{\mathsf{A}t} = \mathsf{uDu}^{-1}, \tag{4}$$

where the EIGENVECTOR MATRIX is

$$\mathsf{u} = [\mathbf{u}_1 \cdots \mathbf{u}_n] \tag{5}$$

and the EIGENVALUE MATRIX is

$$\mathsf{D} = \begin{bmatrix} e^{\lambda_1 t} & 0 & \cdots & 0 \\ 0 & e^{\lambda_2 t} & \cdots & 0 \\ \vdots & \vdots & \ddots & 0 \\ 0 & 0 & \cdots & e^{\lambda_n t} \end{bmatrix}. \tag{6}$$

Now consider

$$e^{\mathsf{A}t}\mathsf{u} = \mathsf{uDu}^{-1}\mathsf{u} = \mathsf{uD}$$
$$= \begin{bmatrix} u_{11} & u_{21} & \cdots & u_{n1} \\ u_{12} & u_{22} & \cdots & u_{n2} \\ \vdots & \vdots & \ddots & \vdots \\ u_{1n} & u_{2n} & \cdots & u_{nn} \end{bmatrix} \begin{bmatrix} e^{\lambda_1 t} & 0 & \cdots & 0 \\ 0 & e^{\lambda_2 t} & \cdots & 0 \\ \vdots & \vdots & \ddots & 0 \\ 0 & 0 & \cdots & e^{\lambda_n t} \end{bmatrix}$$
$$= \begin{bmatrix} u_{11}e^{\lambda_1 t} & \cdots & u_{n1}e^{\lambda_n t} \\ u_{11}e^{\lambda_1 t} & \cdots & u_{n2}e^{\lambda_n t} \\ \vdots & \ddots & \vdots \\ u_{n1}e^{\lambda_1 t} & \cdots & u_{n2}e^{\lambda_n t} \end{bmatrix}. \tag{7}$$

The individual solutions are then

$$\mathbf{x}_i = \left(e^{\mathsf{A}t}\mathsf{u}\right)\cdot\ \hat{\mathbf{e}}_i = \mathbf{u}_i e^{\lambda_i t}, \tag{8}$$

so the homogeneous solution is

$$\mathbf{x} = \sum_{i=1}^{n} c_i \mathbf{u}_i e^{\lambda_i t}, \tag{9}$$

where the c_is are arbitrary constants.

The general procedure is therefore

1. Find the EIGENVALUES of the MATRIX A (λ_1, ..., λ_n) by solving the CHARACTERISTIC EQUATION.
2. Determine the corresponding EIGENVECTORS $\mathbf{u}_1$, ..., $\mathbf{u}_n$.
3. Compute

$$\mathbf{x}_i \equiv e^{\lambda_i t}\mathbf{u}_i \tag{10}$$

for $i = 1, ..., n$. Then the VECTORS $\mathbf{x}_i$ which are REAL are solutions to the homogeneous equation. If A is a 2×2 matrix, the COMPLEX vectors $\mathbf{x}_j$ correspond to REAL solutions to the homogeneous equation given by $\Re(\mathbf{x}_j)$ and $\Im(\mathbf{x}_j)$.
4. If the equation is nonhomogeneous, find the particular solution given by

$$\mathbf{x}^*(t) = \mathsf{X}(t)\int \mathsf{X}^{-1}(t)\mathbf{p}(t)\, dt, \tag{11}$$

where the MATRIX X is defined by

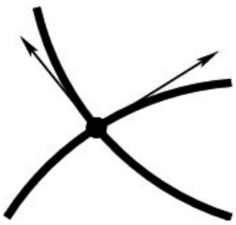
$$\mathsf{X}(t) \equiv [\mathbf{x}_1 \ \cdots \ \mathbf{x}_n]. \tag{12}$$

If the equation is homogeneous so that $\mathbf{p}(t) = \mathbf{0}$, then look for a solution OF THE FORM

$$\mathbf{x} = \xi e^{\lambda t}. \tag{13}$$

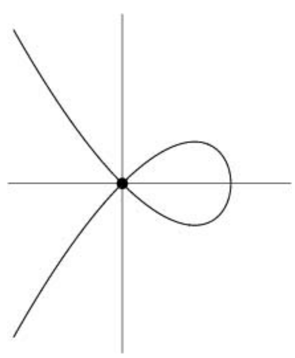
This leads to an equation

$$(\mathsf{A}-\lambda\mathsf{I})\xi = \mathbf{0}, \qquad (14)$$



so ξ is an EIGENVECTOR and λ an EIGENVALUE.

5. The general solution is



$$\mathbf{x}(t) = \mathbf{x}^*(t) + \sum_{i=1}^{n} c_i \mathbf{x}_i. \qquad (15)$$

Ordinary Double Point

Portions of this entry contributed by SERGEI DUZHIN

Let $f : \mathbb{R} \to \mathbb{R}^3$ (or $f : \mathbb{S}^1 \to \mathbb{R}^3$) be a SPACE CURVE. Then a point $p \in \mathrm{im}(f) \subset \mathbb{R}^3$ (where $\mathrm{im}(f)$ denotes the IMMERSION of f) is an ordinary double point if its PREIMAGE under f consists of two values t_1 and t_2, and the two TANGENT VECTORS $f'(t_1)$ and $f'(t_2)$ are noncollinear. Geometrically, this means that, in a NEIGHBORHOOD of p, the curve consists of two transverse branches. Ordinary double points are ISOLATED SINGULARITIES having COXETER-DYNKIN DIAGRAM of type A_1, and also called "nodes" or "simple double points."

The above plot shows the curve $x^3 - x^2 + y^2 = 0$, which has an ordinary double point at the ORIGIN.

A surface in complex 3-space admits at most finitely many ordinary double points. The maximum possible number of ordinary double points $\mu(d)$ for a surface of degree $d = 1, 2, ...,$ are 0, 1, 4, 16, 31, 65, $93 \le \mu(7) \le 104$, $168 \le \mu(8) \le 174$, $216 \le \mu(8) \le 246$, $345 \le \mu(10) \le 360$, $425 \le \mu(11) \le 480$, $576 \le \mu(12) \le 645$ ... (Sloane's A046001; Chmutov 1992, Endraß 1995).

$\mu(4) = 16$ was known to Kummer in 1864 (Chmutov 1992), the fact that $\mu(5) = 31$ was proved by Beauville (1980), and $\mu(6) = 65$ was proved by Jaffe and Ruberman (1994). For $d \ge 3$, the following inequality holds:

$$\mu(d) \le \tfrac{1}{2}[d(d-1) - 3]$$

(Endraß 1995). Examples of ALGEBRAIC SURFACES having the maximum (known) number of ordinary double points are given in the following table.

d	$\mu(d)$	Surface
3	4	CAYLEY CUBIC
4	16	KUMMER SURFACE
5	31	DERVISH
6	65	BARTH SEXTIC
7	93	CHMUTOV SURFACE
8	168	ENDRAß OCTIC
9	216	CHMUTOV SURFACE
10	345	BARTH DECIC
11	425	CHMUTOV SURFACE
12	600	SARTI DODECIC

Ordinary Generating Function

GENERATING FUNCTION

Ordinary Line

Given an arrangement of $n \geq 3$ points, a LINE containing just two of them is called an ordinary line. Kelly and Moser (1958) proved that at least $3n/7$ lines must be ordinary (Guy 1989, p. 903).

Ordinate

The y- (vertical) coordinate of a point in a two dimensional coordinate system. Physicists and astronomers sometimes use the term to refer to the axis itself instead of the distance along it.

See also ABSCISSA, x-AXIS, y-AXIS, z-AXIS

Ore Graph

A GRAPH G in which the sums of the degrees of nonadjacent vertices is greater than the number of nodes n for all subsets of nonadjacent vertices (Ore 1960; Skiena 1990, p. 197). Ore graphs are always HAMILTONIAN, and a HAMILTONIAN CIRCUIT in such a graph can be constructed in polynomial time (Bondy and Chvátal 1976; Skiena 1990, p. 197). The numbers of Ore graphs on $n = 5$, 6, ... nodes are 2, 6, 32, ..., the first few of which are illustrated above.

See also HAMILTONIAN CIRCUIT, HAMILTONIAN GRAPH

Ore Number

HARMONIC DIVISOR NUMBER

Ore's Conjecture

Define the HARMONIC MEAN of the DIVISORS of n

$$H(n) \equiv \frac{\tau(n)}{\sum_{d|n} \frac{1}{d}},$$

where $\tau(n)$ is the TAU FUNCTION (the number of DIVISORS of n). If n is a PERFECT NUMBER, $H(n)$ is an INTEGER. Ore conjectured that if n is ODD, then $H(n)$ is not an INTEGER. This implies that no ODD PERFECT NUMBERS exist.

See also HARMONIC DIVISOR NUMBER, HARMONIC MEAN, PERFECT NUMBER, TAU FUNCTION

Ore's Theorem

If a GRAPH G has $n \geq 3$ VERTICES such that every pair of the n VERTICES which are not joined by an EDGE has a sum of VALENCES which is $\geq n$, then G is HAMILTONIAN.

See also HAMILTONIAN GRAPH

Orientable Surface

A REGULAR SURFACE $M \subset \mathbb{R}^n$ is called orientable if each TANGENT SPACE M_p has a COMPLEX STRUCTURE $J_p : M_p \to M_p$ such that $p \to J_p$ is a continuous function.

See also NONORIENTABLE SURFACE, REGULAR SURFACE

References

Gray, A. *Modern Differential Geometry of Curves and Surfaces with Mathematica, 2nd ed.* Boca Raton, FL: CRC Press, p. 318, 1997.

Orientation (Bundle)

A real VECTOR BUNDLE $\pi : E \to M$ has an orientation if there exists a covering by TRIVIALIZATIONS $U_i \times \mathbb{R}^k$ such that the TRANSITION FUNCTIONS are ORIENTATION preserving. Alternatively, there exists a section of the PROJECTIVIZATION of the top exterior power of the bundle, $P_{\mathbb{R}}(\wedge^k E)$. A bundle is called orientable if there exists an orientation. Hence a bundle E of RANK k is orientable iff $\wedge^k E$ is a TRIVIAL LINE BUNDLE.

An orientation of the TANGENT BUNDLE is equivalent to an orientation on the BASE MANIFOLD. Not all bundles are orientable, as can be seen by the TANGENT BUNDLE of the MÖBIUS STRIP. The nontrivial LINE BUNDLE on the circle is also not orientable.

See also BUNDLE, ORIENTATION (MANIFOLD), ORIENTATION (VECTOR SPACE), VECTOR BUNDLE

Spivak, M. *A Comprehensive Introduction to Differential Geometry, Vol. 1, 2nd ed.* Houston, TX: Publish or Perish, pp. 273–383, 1999.

Orientation (Graph)

An orientation of an UNDIRECTED GRAPH G is an assignment of exactly one direction to each of the edges of G. Only connected, bridgeless graphs can have a strong orientation (Robbins 1939; Skiena 1990, p. 174). An oriented COMPLETE GRAPH is called a TOURNAMENT.

Orientation (Manifold)

An orientation on an n-dimensional MANIFOLD is given by a nowhere vanishing DIFFERENTIAL n-FORM. Alternatively, it is an ORIENTATION for the TANGENT BUNDLE. If an orientation exists on M, then M is called orientable.

Not all MANIFOLDS are orientable, as exemplified by the MÖBIUS STRIP and the KLEIN BOTTLE, illustrated above.

However, an $(n-1)$-dimensional SUBMANIFOLD of $\mathbb{R}^n$ is orientable IFF it has a unit normal vector field. The choice of unit determines the orientation of the submanifold. For example, the SPHERE $\mathbb{S}^2$ is orientable.

Some types of manifolds are always orientable. For instance, COMPLEX MANIFOLDS, including VARIETIES, and also SYMPLECTIC MANIFOLDS are orientable. Also, any unoriented manifold has a double COVER which is oriented.

A map $f : M \to N$ between oriented manifolds of the same dimension is called orientation preserving if the volume form on N pulls back to a positive volume form on M. Equivalently, the differential df maps an ORIENTED BASIS in TM to an ORIENTED BASIS in TN.

Orientation (Plane Curve)

A curve has positive orientation if a region R is on the left when traveling around the outside of R, or on the right when traveling around the inside of R.

Orientation (Vector Space)

An ordered BASIS $v_1, \ldots, v_n$ for a finite-dimensional VECTOR SPACE V defines an orientation. Another basis $w_i = Av_i$ gives the same orientation if the matrix A has a positive determinant, in which case the basis w_i is called oriented.

Any VECTOR SPACE has two possible orientations since the DETERMINANT of an INVERTIBLE MATRIX is either positive or negative. For example, in $\mathbb{R}^2$, $\{e_1, e_2\}$ is one orientation and $\{e_2, e_1\} \sim \{e_1, -e_2\}$ is the other orientation. In three dimensions, the CROSS PRODUCT uses the RIGHT-HAND RULE by convention, reflecting the use of the canonical orientation $\{e_1, e_2, e_3\}$ as $e_1 \times e_2 = e_3$.

An orientation can be given by a nonzero element in the top exterior power of V, i.e. $\wedge^n V$. For example, $e_1 \wedge e_2 \wedge e_3$ gives the canonical orientation on $\mathbb{R}^3$ and $-e_1 \wedge e_2 \wedge e_3$ gives the other orientation.

Some special vector space structures imply an orientation. For example, if ω is a SYMPLECTIC FORM on V, of dimension $2n$, then ω^n gives an orientation. Also, if V is a COMPLEX VECTOR SPACE, then as a real vector space of dimension $2n$, the COMPLEX STRUCTURE gives an orientation.

See also ORIENTATION (MANIFOLD), ORIENTATION (VECTOR BUNDLE)

Orientation (Vectors)

Let θ be the ANGLE between two VECTORS. If $0 < \theta < \pi$, the VECTORS are positively oriented. If $\pi < \theta < 2\pi$, the vectors are negatively oriented.

Two vectors in the plane

$$\begin{bmatrix} x_1 \\ x_2 \end{bmatrix} \text{and} \begin{bmatrix} y_1 \\ y_2 \end{bmatrix}$$

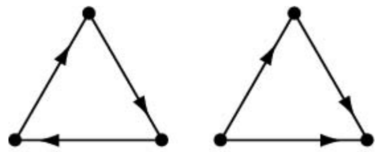
are positively oriented IFF the DETERMINANT

$$D \equiv \begin{vmatrix} x_1 & y_1 \\ x_2 & y_2 \end{vmatrix} > 0,$$

and are negatively oriented IFF the DETERMINANT $D < 0$.

Orientation-Preserving

A nonsingular linear MAP $A : \mathbb{R}^n \to \mathbb{R}^n$ is orientation-preserving if $(A) > 0$.



See also ORIENTATION-REVERSING, ROTATION

Orientation-Reversing

A nonsingular linear MAP $A : \mathbb{R}^n \to \mathbb{R}^n$ is orientation-reversing if $\det(A) < 0$.

Oriented Matroid

The oriented matroid of a finite CONFIGURATION of points extracts relative position and orientation information from the CONFIGURATION. An oriented matroid can be described roughly as a MATROID in which every basis is equipped with an orientation (Richter-Gebert and Ziegler 1997, p. 112).

Origami

The Japanese art of paper folding.

CUBE DUPLICATION and TRISECTION of an ANGLE can be solved using origami, although they cannot be solved using the traditional rules for GEOMETRIC CONSTRUCTIONS.

There are a number of recent very powerful results in origami mathematics. A very general result states that any planar straight-line drawing may be cut out of one sheet of paper by a single straight cut, after appropriate folding (Demaine, Demaine, and Lubiw, 1998, 1999, O'Rourke 1999). Another result is that any polyhedron may be wrapped with a sufficiently large square sheet of paper. This implies that any connected, planar, polygonal region may be covered by a flat origami folded from a single square of paper. Moreover, and 2-coloring of the faces may be realized with paper whose two sides are those colors (Demaine, Demaine, and Mitchell 1999, O'Rourke 1999).

Orr's Theorem

If

$$(1-z)^{\alpha+\beta+\gamma-1/2}\ {}_2F_1(2\alpha,\ 2\beta;\ 2\gamma;\ z) = \sum a_n z^n, \tag{1}$$

where ${}_2F_1(a, b; c; z)$ is a HYPERGEOMETRIC FUNCTION, then

$$\begin{aligned} &{}_2F_1(\alpha,\ \beta;\ \gamma;\ z)\,{}_2F_1\left(\gamma-\alpha+\tfrac{1}{2},\ \gamma-\beta+\tfrac{1}{2};\ \gamma+1;\ z\right) \\ &\quad = \sum_{(\gamma+1/2)_n/(\gamma+1)_n} a_n z^n. \end{aligned} \tag{2}$$

Furthermore, if

$$\begin{aligned} &(1-z)^{\alpha+\beta-\gamma-1/2}\ {}_2F_1(2\alpha-1,\ 2\beta;\ 2\gamma-1;\ z) \\ &\quad = \sum a_n z^n, \end{aligned} \tag{3}$$

then

$$ {}_2F_1(\alpha,\ \beta;\ \gamma;\ z)\Gamma\left(\gamma-\alpha+\tfrac{1}{2},\ \gamma-\beta-\tfrac{1}{2};\ \gamma;\ z\right) = \sum_{(\gamma-1/2)_n/(\gamma)_n} a_n z^n, \qquad (4) $$

where $\Gamma(z)$ is the GAMMA FUNCTION (Bailey 1935, p. 84).

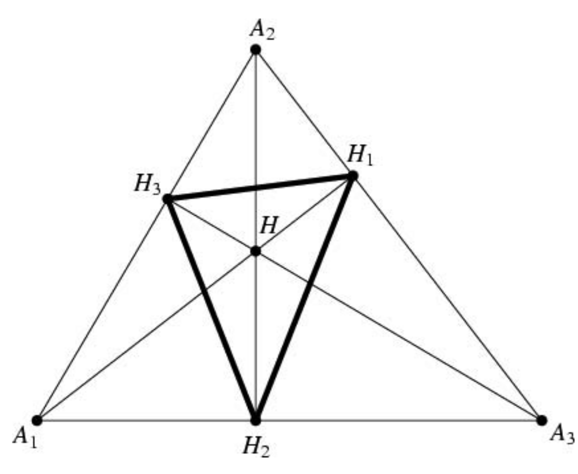
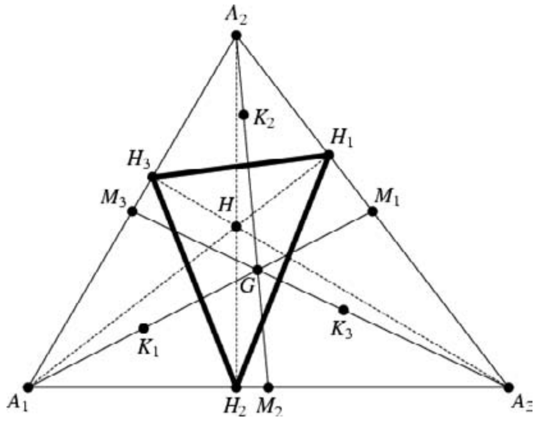
Orthic Axis



The $\Delta H_A H_B H_C$ be the ORTHIC TRIANGLE of a TRIANGLE $\Delta A_B C$. Then each side of each triangle meets the three sides of the other triangle, and the points of intersection lie on a line $O_1 O_2 O_3$ called the orthic axis.

See also ORTHIC TRIANGLE

References



Honsberger, R. §13.2 (ii) in *Episodes in Nineteenth and Twentieth Century Euclidean Geometry.* Washington, DC: Math. Assoc. Amer., p. 151, 1995.

Orthic Triangle

Given a TRIANGLE $\Delta A_1 A_2 A_3$, the TRIANGLE $\Delta H_1 H_2 H_3$ with VERTICES at the feet of the ALTITUDES (perpendiculars from a point to the sides) is called the orthic triangle. The three lines $A_i H_i$ are CONCURRENT at the ORTHOCENTER H of $\Delta A_1 A_2 A_3$. The orthic triangle is

therefore the PEDAL TRIANGLE with respect to H.

Given a triangle $\Delta A_1A_2A_3$, construct the orthic triangle $\Delta H_1H_2H_3$ and determine the SYMMEDIAN POINTS K_1, K_2, and K_3 of $\Delta A_1H_2H_3$, $\Delta H_1A_2H_3$, and $\Delta H_1H_2A_3$, respectively. Then the SYMMEDIANS K_1, K_2, and K_3 of each corner triangle pass through the MIDPOINTS M_1, M_2, and M_3 of the corresponding sides of the original triangle $\Delta A_1A_2A_3$ (Honsberger 1995, p. 75). Moreover, the lines K_1M_1, K_2M_2, and K_3M_3 CONCUR in the CENTROID of $\Delta A_1A_2A_3$.

The sides of the orthic triangle are parallel to the tangents to the CIRCUMCIRCLE at the vertices (Johnson 1929, p. 172).

The centroid of the orthic triangle has TRIANGLE CENTER FUNCTION

$$\alpha = a^2 \cos(B - C)$$

(Casey 1893, Kimberling 1994). The ORTHOCENTER of the orthic triangle has TRIANGLE CENTER FUNCTION

$$\alpha = \cos(2A)\cos(B - C)$$

(Casey 1893, Kimberling 1994). The SYMMEDIAN POINT of the orthic triangle has TRIANGLE CENTER FUNCTION

$$\alpha = \tan A \cos(B - C)$$

(Casey 1893, Kimberling 1994).

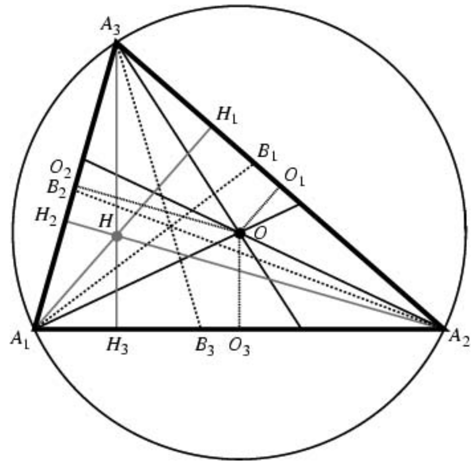
Orthobirotunda

A BIROTUNDA in which the bases are in the same orientation.

Orthocenter

The intersection H of the three ALTITUDES of a TRIANGLE is called the orthocenter. The name was invented by Besant and Ferrers in 1865 while walking on a road leading out of Cambridge, England in the direction of London (Satterly 1962). The TRILINEAR COORDINATES of the orthocenter are

$$\cos B \cos C : \cos C \cos A : \cos A \cos B. \quad (1)$$



If the TRIANGLE is not a RIGHT TRIANGLE, then (1) can be divided through by $\cos A \cos B \cos C$ to give

$$\sec A : \sec B : \sec C. \quad (2)$$

If the triangle is ACUTE, the orthocenter is in the interior of the triangle. In a RIGHT TRIANGLE, the orthocenter is the VERTEX of the RIGHT ANGLE.

When the vertices of a triangle are combined with its orthocenter, any one of the points is the orthocenter of the other three, as first noted by Carnot (Wells

1991). These four points therefore form an ORTHOCENTRIC SYSTEM.

The CIRCUMCENTER O and orthocenter H are ISOGONAL CONJUGATES. The orthocenter lies on the EULER LINE. The orthocenter and NAGEL POINT form a DIAMETER of the FUHRMANN CIRCLE.

Relationships involving the orthocenter include the following:

$$a_1^2 + a_2^2 + a_3^2 + \overline{A_1H}^2 + \overline{A_2H}^2 + \overline{A_3H}^2 = 12R^2 \qquad (3)$$

$$\overline{A_1H} + \overline{A_2H} + \overline{A_3H} = 2(r + R), \qquad (4)$$

$$\overline{A_1H}^2 + \overline{A_2H}^2 + \overline{A_3H}^2 = 4R^2 - 4Rr, \qquad (5)$$

where r is the INRADIUS and R is the CIRCUMRADIUS (Johnson 1929, p. 191).

Any HYPERBOLA circumscribed on a TRIANGLE and passing through the orthocenter is RECTANGULAR, and has its center on the NINE-POINT CIRCLE (Falisse 1920, Vandeghen 1965).

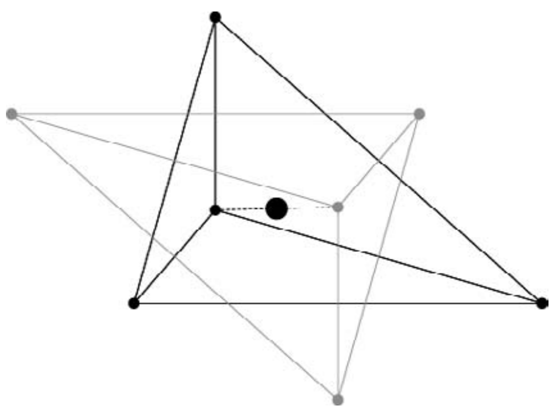
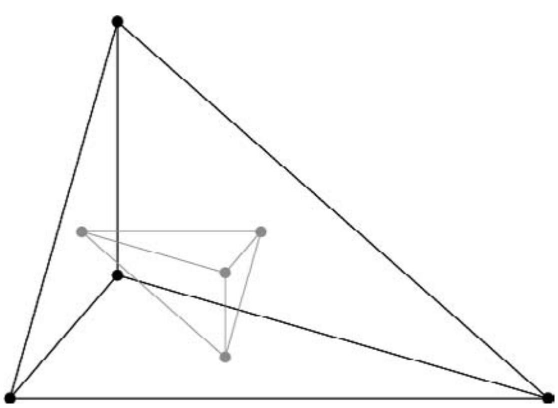
Orthocentric Quadrilateral



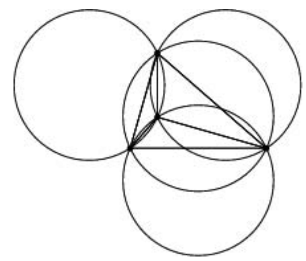
If two pairs of opposite sides of a COMPLETE QUADRILATERAL are pairs of PERPENDICULAR lines, the QUADRILATERAL is said to be orthocentric. In such a case, the remaining sides are also PERPENDICULAR.

See also ORTHOCENTRIC QUADRANGLE, ORTHOCENTRIC SYSTEM

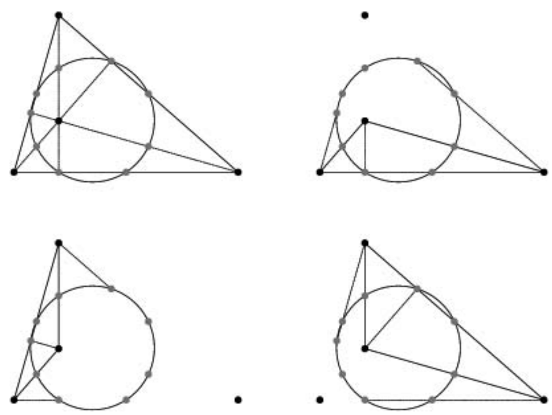


Orthocentric System

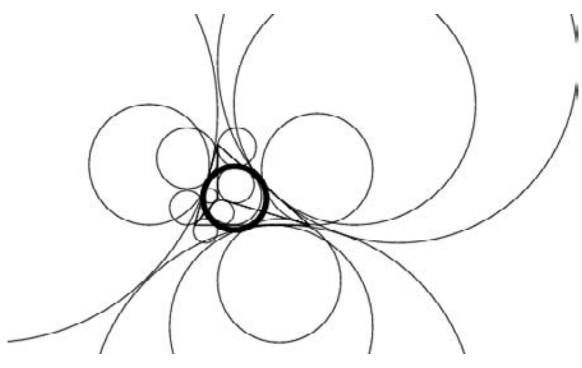
A set of four points, one of which is the ORTHOCENTER of the other three. In an orthocentric system, each point is the ORTHOCENTER of the TRIANGLE of the other three, as illustrated above (Coxeter and Greitzer 1967, p. 39). The INCENTER and EXCENTERS of a TRIANGLE are an orthocentric system.



The centers of the CIRCUMCIRCLES of the points in an orthocentric system form another orthocentric system congruent to the first, and are the reflection of the original points in their common NINE-POINT CENTER (Wells 1991).



The centroids of the points in an orthocentric system form another orthocentric system similar to the first, but one third the size (Wells 1991).



The sum of the squares of any nonadjacent pair of connectors of an orthocentric system equals the square of the DIAMETER of the CIRCUMCIRCLE. Orthocentric systems are used to define ORTHOCENTRIC COORDINATES.

The four CIRCUMCIRCLES of points in an orthocentric system taken three at a time (illustrated above) have equal RADIUS (Wells 1991).

The four triangles of an orthocentric system have a common NINE-POINT CIRCLE, illustrated above. Furthermore, this circle is tangent to the 16 incircles and excircles of the four triangles (Wells 1991).

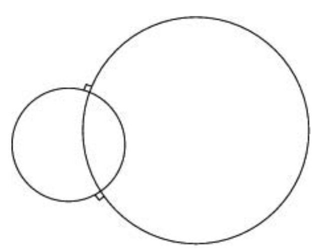
Orthogonal Basis

A BASIS of vectors **x** which satisfy



$$x_j x_k = C_{jk} \delta_{jk}$$

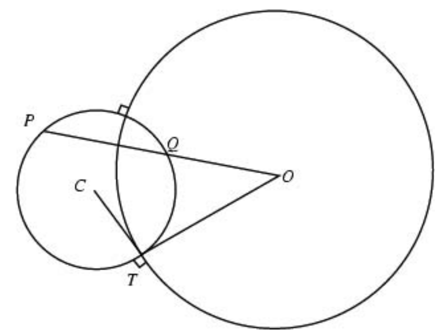
$$x^\mu x_\nu = C_\nu^\mu \delta_\nu^\mu,$$

where C_{jk}, C_ν^μ are constants (not necessarily equal to 1) and δ_{jk} is the KRONECKER DELTA.

See also BASIS, ORTHONORMAL BASIS, SPECTRUM (OPERATOR)

Orthogonal Circles

Orthogonal circles are ORTHOGONAL CURVES, i.e., they cut one another at RIGHT ANGLES. Two CIRCLES with equations



$$x^2 + y^2 + 2gx + 2fy + c = 0 \quad (1)$$

$$x^2 + y^2 + 2g'x + 2f'y + c' = 0 \quad (2)$$

are orthogonal if

$$2gg' + 2ff' = c + c'. \quad (3)$$

The RADICAL LINES of three given circles concur in the RADICAL CENTER R. If a circle with center R cuts any one of the three circles orthogonally, it cuts all three orthogonally. This circle is called the orthogonal circle (or RADICAL CIRCLE) of the system. The orthogonal circle is the LOCUS of a point whose POLARS with respect to the three given circles are concurrent (Lachlan 1893, p. 237).

A theorem of Euclid states that, for the orthogonal circles in the above diagram,

$$OP \times OQ = OT^2 \quad (4)$$

(Dixon 1991, p. 65).

Orthogonal Complement

The orthogonal complement of a SUBSPACE W of $\mathbb{R}^n$ is denoted $W^\perp$.

See also FREDHOLM'S THEOREM, ORTHOGONAL DECOMPOSITION

Orthogonal Coordinate System

A system of CURVILINEAR COORDINATES in which each family of surfaces intersects the others at right angles.

Orthogonal CURVILINEAR COORDINATES satisfy the additional constraint that

$$\hat{\mathbf{u}}_i \cdot \hat{\mathbf{u}}_j = \delta_{ij}. \tag{1}$$

Therefore, the LINE ELEMENT becomes

$$d\mathbf{s}^2 = d\mathbf{r} \cdot d\mathbf{r} = h_1^2\, du_1^2 + h_2^2\, du_2^2 + h_3^2\, du_3^2 \tag{2}$$

and the VOLUME ELEMENT is

$$\begin{aligned} dV &= |(h_1 \hat{\mathbf{u}}_1\, du_1) \cdot (h_2 \hat{\mathbf{u}}_2\, du_2) \times (h_3 \hat{\mathbf{u}}_3\, du_3)| \\ &= h_1 h_2 h_3\, du_1\, du_2\, du_3 \\ &= \left| \frac{\partial r}{\partial u_1} \cdot \frac{\partial r}{\partial u_2} \times \frac{\partial r}{\partial u_3} \right| du_1\, du_2\, du_3 \\ &= \begin{vmatrix} \frac{\partial x}{\partial u_1} & \frac{\partial x}{\partial u_2} & \frac{\partial x}{\partial u_3} \\ \frac{\partial y}{\partial u_1} & \frac{\partial y}{\partial u_2} & \frac{\partial y}{\partial u_3} \\ \frac{\partial z}{\partial u_1} & \frac{\partial z}{\partial u_2} & \frac{\partial z}{\partial u_3} \end{vmatrix} du_1\, du_2\, du_3 \\ &= \left| \frac{\partial(x, y, z)}{\partial(u_1, u_2, u_3)} \right| du_1\, du_2\, du_3, \end{aligned} \tag{3}$$

where the latter is the JACOBIAN.

For surfaces of first degree, the only 3-D coordinate system of surfaces having orthogonal intersections is CARTESIAN COORDINATES (Moon and Spencer 1988, p. 1). Including degenerate cases, there are 11 sets of quadratic surfaces having orthogonal coordinates. Furthermore, LAPLACE'S EQUATION and the HELMHOLTZ DIFFERENTIAL EQUATION are separable in all of these coordinate systems (Moon and Spencer 1988, p. 1).

Planar orthogonal curvilinear coordinate systems of degree two or less include 2-D CARTESIAN COORDINATES and POLAR COORDINATES.

3-D orthogonal curvilinear coordinate systems of degree two or less include BIPOLAR CYLINDRICAL COORDINATES, BISPHERICAL COORDINATES, 3-D CARTESIAN COORDINATES, CONFOCAL ELLIPSOIDAL COORDINATES, CONFOCAL PARABOLOIDAL COORDINATES, CONICAL COORDINATES, CYCLIDIC COORDINATES, CYLINDRICAL COORDINATES, ELLIPSOIDAL COORDINATES, ELLIPTIC CYLINDRICAL COORDINATES, OBLATE SPHEROIDAL COORDINATES, PARABOLIC COORDINATES, PARABOLIC CYLINDRICAL COORDINATES, PARABOLOIDAL COORDINATES, PROLATE SPHEROIDAL COORDINATES, SPHERICAL COORDINATES, and TOROIDAL COORDINATES. These are degenerate cases of the CONFOCAL ELLIPSOIDAL COORDINATES.

Orthogonal coordinate systems can also be built from fourth-order (in particular, CYCLIDIC COORDINATES) and higher surfaces (Bôcher 1894), but are generally less important in solving physical problems than are quadratic surfaces (Moon and Spencer 1988, p. 1).

Orthogonal Curves

Two intersecting curves which are PERPENDICULAR at their INTERSECTION are said to be orthogonal.

Orthogonal Decomposition

This entry contributed by VIKTOR BENGTSSON

The orthogonal decomposition of a VECTOR $\mathbf{y}$ in $\mathbb{R}^n$ is the sum of a vector in a SUBSPACE W of $\mathbb{R}^n$ and a vector in the ORTHOGONAL COMPLEMENT $W^\perp$ to W.

The orthogonal decomposition theorem states that if W is a SUBSPACE of $\mathbb{R}^n$, then each vector $\mathbf{y}$ in $\mathbb{R}^n$ can be written uniquely in the form

$$\mathbf{y} = \hat{\mathbf{y}} + \mathbf{x},$$

where $\hat{\mathbf{y}}$ is in W and $\mathbf{z}$ is in $W^\perp$. In fact, if $\{\mathbf{u}_1, \mathbf{u}_2, \ldots, \mathbf{u}_p\}$ is any ORTHOGONAL BASIS of W, then

$$\hat{\mathbf{y}} = \frac{\mathbf{y} \cdot \mathbf{u}_1}{\mathbf{u}_1 \cdot \mathbf{u}_1}\mathbf{u}_1 + \frac{\mathbf{y} \cdot \mathbf{u}_2}{\mathbf{u}_2 \cdot \mathbf{u}_2}\mathbf{u}_2 + \ldots + \frac{\mathbf{y} \cdot \mathbf{u}_p}{\mathbf{u}_p \cdot \mathbf{u}_p}\mathbf{u}_p,$$

and $\mathbf{z} = \mathbf{y} - \hat{\mathbf{y}}$.

Geometrically, $\hat{\mathbf{y}}$ is the ORTHOGONAL PROJECTION of $\mathbf{y}$ onto the SUBSPACE W and $\mathbf{z}$ is a vector orthogonal to $\hat{\mathbf{y}}$

Orthogonal Functions

Two functions $f(x)$ and $g(x)$ are orthogonal on the interval $a \le x \le b$ if

$$\langle f(x)|g(x)\rangle \equiv \int_a^b f(x)g(x)\,dx = 0.$$

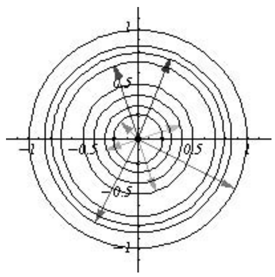
See also ORTHOGONAL POLYNOMIALS, ORTHONORMAL FUNCTIONS

Orthogonal Group

For every DIMENSION $n > 0$, the orthogonal group $O(n)$ is the GROUP of $n \times n$ ORTHOGONAL MATRICES. These matrices form a GROUP because they are CLOSED under multiplication and taking inverses.

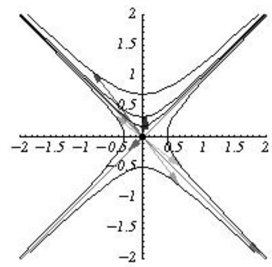
Thinking of a matrix as given by n^2 coordinate functions, the set of matrices is identified with $\mathbb{R}^{n^2}$. The orthogonal matrices are the solutions to the n^2 equations

$$AA^T = I, \tag{1}$$



where I is the IDENTITY MATRIX, which are redundant. Only $n(n+1)/2$ of these are independent, leaving $n(n-1)/2$ "free variables." In fact, the orthogonal group is a smooth $n(n-1)/2$ dimensional SUBMANIFOLD.

Because the orthogonal group is a group and a manifold, it is a LIE GROUP. $O(n)$ has a TANGENT SPACE at the identity that is the LIE ALGEBRA of SKEW SYMMETRIC MATRICES $o(n)$. In fact, the orthogonal group is a COMPACT LIE GROUP.



The DETERMINANT of an ORTHOGONAL MATRIX is either 1 or -1, and so the orthogonal group has two COMPONENTS. The component containing the identity is a the SPECIAL ORTHOGONAL GROUP $SO(n)$. For example, The GROUP $O(2)$ has GROUP ACTION on the plane that is a rotation:

$$O(2) = \left\{ \begin{bmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{bmatrix} \right\} \cup \left\{ \begin{bmatrix} -\cos\theta & \sin\theta \\ \sin\theta & \cos\theta \end{bmatrix} \right\}, \tag{2}$$

where θ is any real number in $[0, 2\pi)$. These matrices preserve the QUADRATIC FORM $x^2 + y^2$, and so they also preserve CIRCLES $x^2 + y^2 = r^2$, which are the ORBITS.

As a manifold, $O(2)$ is a one dimensional, two disjoint copies of the CIRCLE. The SUBGROUP $SO(2)$ is not a NORMAL SUBGROUP, so $O(2)$ is the SEMIDIRECT PRODUCT of the circle $SO(2)$ and $\mathbb{Z}_2$.

There are several generalizations of the orthogonal group. First, it is possible to define the orthogonal group for any SYMMETRIC QUADRATIC FORM Q with SIGNATURE (p, q). The group of matrices A which preserve Q, that is,

$$Q(v, w) = Q(Av, Aw), \tag{3}$$

is denoted $O(p, q)$. The LORENTZ GROUP is $O(3, 1)$. For example, the matrices

$$A = \begin{bmatrix} \cosh t & \sinh t \\ \sinh t & \cosh t \end{bmatrix} \tag{4}$$

are elements of $O(1, 1)$. They preserve the QUADRATIC FORM $x^2 - y^2$ so they preserve the HYPERBOLAS $x^2 - y^2 = c$.

Instead of using real numbers for the coefficients, it is possible to use coefficients from any FIELD $\mathbb{F}$, in which case it is denoted $O(n, \mathbb{F})$. The orthogonal matrices still satisfy $AA^t = I$. For example, $O(2, \mathbb{F}_{23})$ contains

$$\begin{bmatrix} 11 & 15 \\ 15 & 12 \end{bmatrix}, \tag{5}$$

and has 48 elements in total.

Of course, $O(p, q, \mathbb{F})$ denotes the group of matrices which preserve the SYMMETRIC QUADRATIC FORM of SIGNATURE (p, q), with coefficients in the field $\mathbb{F}$. When $\mathbb{F}$ is not $\mathbb{R}$ or $\mathbb{C}$, these are called LIE-TYPE GROUPS.

When the coefficients are COMPLEX NUMBERS, it is called the complex orthogonal group, which is much

different from the UNITARY GROUP. For example, matrices OF THE FORM

$$A = \begin{bmatrix} \cos z & -\sin z \\ \sin z & \cos z \end{bmatrix} \quad (6)$$

are in $O(2, \mathbb{C})$. In particular, $O(n, \mathbb{C})$ is not COMPACT. The equations defining $O(n)$ in AFFINE SPACE are polynomials of degree two. Consequently, $O(n)$ is a LINEAR ALGEBRAIC GROUP.

The numbers of subgroups $s(n)$ of orders $n = 1, 2, 3$, ... in the orthogonal group $O(3)$ are 1, 3, 1, 5, 1, 5, 1, 7, 1, 5, 1, 8, ... (Sloane's A001051), i.e., a repeating sequence of copies of $\{1, 5, 1, 7\}$ with the exceptions $s(2) = 3$, $s(4) = 5$, $s(12) = 8$, $s(24) = 10$, and $s(48) = s(60) = s(120) = 8$.

Orthogonal Group Representations

Two representations of a GROUP χ_i and χ_j are said to be orthogonal if

$$\sum_R \chi_i(R)\chi_j(R) = 0$$

for $i \neq j$, where the sum is over all elements R of the representation.

See also GROUP

Orthogonal Lines

Two or more LINES or LINE SEGMENTS which are PERPENDICULAR are said to be orthogonal.

See also ORTHOGONAL CURVES, PERPENDICULAR, RIGHT ANGLE

Orthogonal Matrix

A $n \times n$ matrix A is an orthogonal matrix if

$$\mathsf{A}\mathsf{A}^{\mathrm{T}} = \mathsf{I}, \quad (1)$$

where A^{T} is the TRANSPOSE of A and I is the IDENTITY MATRIX. In particular, an orthogonal matrix is always invertible, and

$$\mathsf{A}^{-1} = \mathsf{A}^{\mathrm{T}} \quad (2)$$

(Note that transpose is a much simpler computation than inverse.) For example,

$$\mathsf{A} = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix} \quad (3)$$

$$\mathbf{A} = \frac{1}{3} \begin{bmatrix} 2 & -2 & 1 \\ 1 & 2 & 2 \\ 2 & 1 & -2 \end{bmatrix} \quad (4)$$

are orthogonal matrices. A matrix m can be tested to see if it is orthogonal using the *Mathematica* function

```
OrthogonalQ[m_List?MatrixQ]                    :=
(Transpose[m].m  = =  IdentityMatrix@Length@m)
```

The rows of an orthogonal matrix are an ORTHONORMAL BASIS. That is, each row has length one, and are mutually perpendicular. Similarly, the columns are also an orthonormal basis. In fact, given any orthonormal basis, the matrix whose rows are that basis is an orthogonal matrix. It is automatically the case that the columns are another orthonormal basis.

The orthogonal matrices are precisely those matrices which preserve the INNER PRODUCT

$$\langle v, w \rangle = \langle \mathsf{A}_v, \mathsf{A}_w \rangle. \quad (5)$$

Also, the determinant of A is either 1 or -1. As a subset of $\mathbb{R}^{n^2}$, the orthogonal matrices are not CONNECTED since the determinant is a CONTINUOUS FUNCTION. Instead, there are two COMPONENTS corresponding to whether the determinant is 1 or -1. The orthogonal matrices with $A = 1$ are rotations, and such a matrix is called a SPECIAL ORTHOGONAL MATRIX.

The product of two orthogonal matrices is another orthogonal matrix. In addition, the inverse of an orthogonal matrix is an orthogonal matrix, as is the IDENTITY MATRIX. Hence the set of orthogonal matrices form a GROUP, called the ORTHOGONAL GROUP $O(n)$.

Orthogonal Polynomials

Orthogonal polynomials are classes of POLYNOMIALS $\{p_n(x)\}$ over a range $[a, b]$ which obey an ORTHOGONALITY relation

$$\int_a^b w(x)p_m(x)p_n(x)\,dx = \delta_{mn}c_n, \tag{1}$$

where $w(x)$ is a WEIGHTING FUNCTION and δ is the KRONECKER DELTA. If $c_n = 1$, then the POLYNOMIALS are not only orthogonal, but orthonormal.

Orthogonal polynomials have very useful properties in the solution of mathematical and physical problems. Just as FOURIER SERIES provide a convenient method of expanding a periodic function in a series of linearly independent terms, orthogonal polynomials provide a natural way to solve, expand, and interpret solutions to many types of important DIFFERENTIAL EQUATIONS. Orthogonal polynomials are especially easy to generate using GRAM-SCHMIDT ORTHONORMALIZATION. Abramowitz and Stegun (1972, pp. 774–775) give a table of common orthogonal polynomials.

Type	Interval	$w(x)$	c_n
CHEBYSHEV POLYNOMIAL OF THE FIRST KIND	$[-1, 1]$	$(1-x^2)^{-1/2}$	$\begin{cases}\frac{1}{2}\pi & \text{for } n=0\\ \pi & \text{otherwise}\end{cases}$
CHEBYSHEV POLYNOMIAL OF THE SECOND KIND	$[-1, 1]$	$\sqrt{1-x^2}$	$\frac{1}{2}\pi$
HERMITE POLYNOMIAL	$(-\infty, \infty)$	e^{-x^2}	$\sqrt{\pi}\,2^n\,n!$
JACOBI POLYNOMIAL	$(-1, 1)$	$(1-x)^\alpha(1+x)^\beta$	h_n
LAGUERRE POLYNOMIAL	$[0, \infty)$	e^{-x}	1
LAGUERRE POLYNOMIAL (Associated)	$[0, \infty)$	$x^k e^{-x}$	$\frac{(n+k)!}{n!}$
LEGENDRE POLYNOMIAL	$[-1, 1]$	1	$\frac{2}{2n+1}$
ULTRASPHERICAL POLYNOMIAL	$[-1, 1]$	$(1-x^2)^{\alpha-1/2}$	$\begin{cases}\frac{2^{1-2\alpha}}{n!(n+\alpha)}\frac{\pi\Gamma(n+2\alpha)}{[\Gamma(\alpha)]^2} & \text{for } \alpha\neq 0\\ \frac{2\pi}{n^2} & \text{for } \alpha\neq 0.\end{cases}$

In the above table, the normalization constant is the value of

$$c_n \equiv \int w(x)[p_n(x)]^2\,dx \tag{2}$$

and

$$h_n \equiv \frac{2^{\alpha+\beta+1}}{2n+\alpha+\beta+1}\frac{\Gamma(n+\alpha+1)\Gamma(n+\beta+1)}{n!\Gamma(n+\alpha+\beta+1)}, \tag{3}$$

where $\Gamma(z)$ is a GAMMA FUNCTION.

The ROOTS of orthogonal polynomials possess many rather surprising and useful properties. For instance, let $x_1 < x_2 < \ldots < x_n$ be the ROOTS of the $p_n(x)$ with $x_0 = a$ and $x_{n+1} = b$. Then each interval $[x_\nu, x_{\nu+1}]$ for $\nu = 0, 1, \ldots, n$ contains exactly one ROOT of $p_{n+1}(x)$. Between two ROOTS of $p_n(x)$ there is at least one ROOT of $p_m(x)$ for $m > n$.

Let c be an arbitrary REAL constant, then the POLYNOMIAL

$$p_{n+1}(x) - cp_n(x) \tag{4}$$

has $n+1$ distinct REAL ROOTS. If $c > 0$ ($c < 0$), these ROOTS lie in the interior of $[a, b]$, with the exception of the greatest (least) ROOT which lies in $[a, b]$ only for

$$c \leq \frac{p_{n+1}(b)}{p_n(b)} \quad \left(c \geq \frac{p_{n+1}(a)}{p_n(a)}\right). \tag{5}$$

The following decomposition into partial fractions holds

$$\frac{p_n(x)}{p_{n+1}(x)} = \sum_{\nu=0}^{n} \frac{l_\nu}{x-\xi}, \tag{6}$$

where $\{\xi_\nu\}$ are the ROOTS of $p_{n+1}(x)$ and

$$l_\nu = \frac{p_n(\xi_\nu)}{p'_{n+1}(\xi_\nu)}$$

$$= \frac{p'_{n+1}(\xi_\nu)p_n(\xi_\nu) - p'_n(\xi_\nu)'p_{n+1}(\xi_\nu)}{[p'_{n+1}(\xi_\nu)]^2} > 0. \tag{7}$$

Another interesting property is obtained by letting $\{p_n(x)\}$ be the orthonormal set of POLYNOMIALS associated with the distribution $d\alpha(x)$ on $[a, b]$. Then the CONVERGENTS R_n/S_n of the CONTINUED FRACTION

$$\frac{1}{A_1x+B_1} - \frac{C_2}{A_2x+B_2} - \frac{C_3}{A_3x+B_3} - \ldots - \frac{C_n}{A_nx+B_n} + \ldots \tag{8}$$

are given by

$$R_n = R_n(x)$$

$$= c_0^{-3/2}\sqrt{c_0c_2 - c_1^2}\int_a^b \frac{p_n(x)-p_n(t)}{x-t}\,d\alpha(t) \tag{9}$$

$$S_n = S_n(x) = \sqrt{c_0}\,p_n(x), \tag{10}$$

where $n = 0, 1, \ldots$and

$$c_n = \int_a^b x^n\,d\alpha(x). \tag{11}$$

Furthermore, the ROOTS of the orthogonal polyno-

mials $p_n(x)$ associated with the distribution $d\alpha(x)$ on the interval $[a, b]$ are REAL and distinct and are located in the interior of the interval $[a, b]$.

Orthogonal Projection

A PROJECTION of a figure by parallel rays. In such a projection, tangencies are preserved. Parallel lines project to parallel lines. The ratio of lengths of parallel segments is preserved, as is the ratio of areas.

Any TRIANGLE can be positioned such that its shadow under an orthogonal projection is EQUILATERAL. Also, the MEDIANS of a TRIANGLE project to the MEDIANS of the image TRIANGLE. ELLIPSES project to ELLIPSES, and any ELLIPSE can be projected to form a CIRCLE. The center of an ELLIPSE projects to the center of the image ELLIPSE. The CENTROID of a TRIANGLE projects to the CENTROID of its image. Under an ORTHOGONAL TRANSFORMATION, the MIDPOINT ELLIPSE can be transformed into a CIRCLE INSCRIBED in an EQUILATERAL TRIANGLE.

SPHEROIDS project to ELLIPSES (or CIRCLE in the DEGENERATE case).

In an orthogonal projection, any vector v can be written $v = v_W + v_{W^\perp}$, so

$$\langle v, Pw\rangle = \langle v_W, Pw\rangle = \langle Pv, w\rangle,$$

and the PROJECTION MATRIX is a SYMMETRIC MATRIX IFF the PROJECTION is orthogonal. The following *Mathematica* function will test whether a PROJECTION MATRIX is an orthogonal projection.

```
OrthogProjectionMatrixQ[a_List?MatrixQ] :=
   (a.a == a && Transpose[a] == a)
```

The following *Mathematica* function gives the PROJECTION MATRIX for orthogonal projection onto a subspace spanned by a given basis.

```
<<LinearAlgebra`Orthogonalization`;
 OrthogProjectMatrixOntoBasis[a_List?MatrixQ]
:=
  Module[{a1 = GramSchmidt[a]},
   Transpose[a1].a1]
  ]
```

For instance, `OrthogProjectMatrixOntoBasis[{{1, 2, 3}}]` yields {{1/14, 1/7, 3/14}, {1/7, 2/7, 3/7}, {3/14, 3/7, 9/14}}..

See also PROJECTION, PROJECTION MATRIX

Orthogonal Rotation Group

ORTHOGONAL GROUP

Orthogonal Set

A subset $\{v_1, \ldots, v_k\}$ of a VECTOR SPACE V, with the INNER PRODUCT $\langle , \rangle$, is called orthogonal if $\langle v_i, v_j\rangle = 0$ when $i \neq j$. That is, the vectors are mutually PERPENDICULAR.

Note that there is no restriction on the lengths of the vectors. If the vectors in an orthogonal set all have length one, then they are ORTHONORMAL.

The notion of orthogonal makes sense for an abstract VECTOR SPACE over any field as long as there is a SYMMETRIC QUADRATIC FORM. The usual orthogonal sets and groups in EUCLIDEAN SPACE can be generalized, with applications to special relativity, DIFFERENTIAL GEOMETRY, and ABSTRACT ALGEBRA.

See also CLIFFORD ALGEBRA, HOMOGENEOUS SPACE, HYPERBOLIC SPACE, LIE GROUP, LORENTZIAN INNER PRODUCT, ORTHOGONAL GROUP, ORTHOGONAL TRANSFORMATION, ORTHONORMAL BASIS, SYMMETRIC QUADRATIC FORM

Orthogonal Subspaces

Two SUBSPACES S_1 and S_2 of $\mathbb{R}^n$ are said to be orthogonal if $\mathbf{v}_1 \cdot \mathbf{v}_2 = 0$ for all $\mathbf{v}_1 \in S_1$ and all $\mathbf{v}_2 \in S_2$.

Orthogonal Surfaces

Families of surfaces which are mutually orthogonal. Up to three families of surfaces may be orthogonal in 3-D. The simplest example of three orthogonal surfaces in 3-D are orthogonal planes, but three confocal conic surfaces are also mutually orthogonal.

References

Wells, D. *The Penguin Dictionary of Curious and Interesting Geometry.* London: Penguin, p. 166, 1991.

Orthogonal Tensors

Orthogonal CONTRAVARIANT and COVARIANT satisfy

$$g_{ik}g^{ij} = \delta^j_k,$$

where δ^k_j is the KRONECKER DELTA.

See also CONTRAVARIANT TENSOR, COVARIANT TENSOR

Orthogonal Transformation

An orthogonal transformation is a LINEAR TRANSFORMATION $T : V \to V$ which preserves a SYMMETRIC INNER PRODUCT. In particular, an orthogonal transformation (technically, an *orthonormal transformation*) preserves lengths of vectors and angles between vectors,

$$\langle v,\ w\rangle = \langle Tv,\ Tw\rangle. \tag{1}$$

In addition, an orthogonal transformation is either a rigid ROTATION or a ROTOINVERSION (a rotation followed by a flip). (Flipping and then rotating can be realized by first rotating in the reverse direction and then flipping). Orthogonal transformations correspond to and may be represented using ORTHOGONAL MATRICES.

The set of orthonormal transformations forms the ORTHOGONAL GROUP, and an orthonormal transformation can be realized by an ORTHOGONAL MATRIX.

Any linear transformation in 3-D

$$x'_1 = a_{11}x_1 + a_{12}x_2 + x_{13}x_3 \tag{2}$$

$$x'_2 = a_{21}x_1 + a_{22}x_2 + a_{23}x_3 \tag{3}$$

$$x'_3 = a_{31}x_1 + a_{32}x_2 + a_{33}x_3 \tag{4}$$

satisfying the ORTHOGONALITY CONDITION

$$a_{ij}a_{ik} = \delta_{jk}, \tag{5}$$

where EINSTEIN SUMMATION has been used and δ_{ij} is the KRONECKER DELTA, is an orthogonal transformation. If $A : \mathbb{R}^n \to \mathbb{R}^n$ is an orthogonal transformation, then $\det(A) = \pm 1$.

See also INNER PRODUCT, LIE GROUP, LINEAR TRANSFORMATION, LORENTZ TRANSFORMATION, MATRIX, ORTHOGONAL MATRIX, ORTHOGONAL GROUP, ORTHOGONALITY CONDITION, SPIN GROUP, ROTATION, ROTOINVERSION, SYMMETRIC QUADRATIC FORM

Orthogonal Vectors

Two vectors **u** and **v** whose DOT PRODUCT is $\mathbf{u} \cdot \mathbf{v} = 0$ (i.e., the vectors are PERPENDICULAR) are said to be orthogonal. In 3-space, three vectors can be mutually perpendicular.

See also DOT PRODUCT, ORTHONORMAL VECTORS, PERPENDICULAR

Orthogonality Condition

A linear transformation

$$x'_1 = a_{11}x_1 + a_{12}x_2 + x_{13}x_3$$

$$x'_2 = a_{21}x_1 + a_{22}x_2 + a_{23}x_3$$

$$x'_3 = a_{31}x_1 + a_{32}x_2 + a_{33}x_3,$$

is said to be an ORTHOGONAL TRANSFORMATION if it satisfies the orthogonality condition

$$a_{ij}a_{ik} = \delta_{jk},$$

where EINSTEIN SUMMATION has been used and δ_{ij} is the KRONECKER DELTA.

See also ORTHOGONAL TRANSFORMATION

Orthogonality Theorem

GROUP ORTHOGONALITY THEOREM

Orthographic Projection

A projection from infinity which preserves neither AREA nor angle.

$$x = \cos\phi \sin(\lambda - \lambda_0) \quad (1)$$

$$y = \cos\phi_1 \sin\phi - \sin\phi_1 \cos\phi \cos(\lambda - \lambda_0). \quad (2)$$

The inverse FORMULAS are

$$\phi = \sin^{-1}\left(\cos c \sin\phi_1 + \frac{y \sin c \cos\phi_1 +}{\rho}\right) \quad (3)$$

$$\lambda = \lambda_0 + \tan^{-1}\left(\frac{x \sin c}{\rho \cos\phi_1 \cos c - y \sin\phi_1 \sin c}\right), \quad (4)$$

where

$$\rho = \sqrt{x^2 + y^2} \quad (5)$$

$$c = \sin^{-1}\rho. \quad (6)$$

Orthologic Triangles

Two TRIANGLES $A_1B_1C_1$ and $A_2B_2C_2$ are orthologic if the perpendiculars from the VERTICES A_1, B_1, C_1 on the sides B_2C_2, A_2C_2, and A_2B_2 pass through one point. This point is known as the orthology center of TRIANGLE 1 with respect to TRIANGLE 2.

Orthomorphic Projection

CONFORMAL PROJECTION

Orthonormal Basis

A subset $\{v_1, \ldots, v_k\}$ of a VECTOR SPACE V, with the INNER PRODUCT $\langle , \rangle$, is called orthonormal if $\langle v_i, v_j \rangle = 0$ when $i \neq j$. That is, the vectors are mutually PERPENDICULAR. Moreover, they are all required to have length one: $\langle v_i, v_i \rangle = 1$.

An orthonormal set must be linearly independent, and so it is a BASIS for the space it SPANS. Such a basis is called an orthonormal basis.

The simplest example of an orthonormal basis is the standard basis e_i for EUCLIDEAN SPACE $\mathbb{R}^n$. The vector e_i is the vector with all 0s except for a 1 in the ith coordinate. For example, $e_1 = (1, 0, \ldots, 0)$. A rotation (or flip) through the origin will send an orthonormal set to another orthonormal set. In fact, given any orthonormal basis, there is a rotation, or rotation combined with a flip, which will send the orthonormal basis to the standard basis. These are precisely the transformations which preserve the inner product, and are called ORTHOGONAL TRANSFORMATIONS.

Usually when one needs a basis to do calculations, it is convenient to use an orthonormal basis. For example, the formula for a PROJECTION is much simpler with an orthonormal basis. The savings in effort make it worthwhile to find an orthonormal basis before doing such a calculation. GRAM-SCHMIDT ORTHONORMALIZATION is a popular way to find an orthonormal basis.

Another instance when orthonormal bases arise is as a set of EIGENVECTORS for a SYMMETRIC MATRIX. For a general matrix, the set of eigenvectors may not be orthonormal, or even be a basis.

See also BASIS (VECTOR SPACE), DOT PRODUCT, INNER PRODUCT, KRONECKER DELTA, LIE GROUP, LORENTZIAN INNER PRODUCT, MATRIX, ORTHOGONAL BASIS ORTHOGONAL MATRIX, ORTHOGONAL GROUP, ORTHOGONAL TRANSFORMATION, PROJECTION (VECTOR SPACE), SYMMETRIC QUADRATIC FORM

Orthonormal Functions

A pair of functions $\phi_i(x)$ and $\phi_j(x)$ are orthonormal if they are ORTHOGONAL and each normalized. These two conditions can be succinctly written as

$$\int_a^b \phi_i(x)\phi_j(x)w(x)\,dx = \delta_{ij},$$

where $w(x)$ is a WEIGHTING FUNCTION and δ_{ij} is the KRONECKER DELTA.

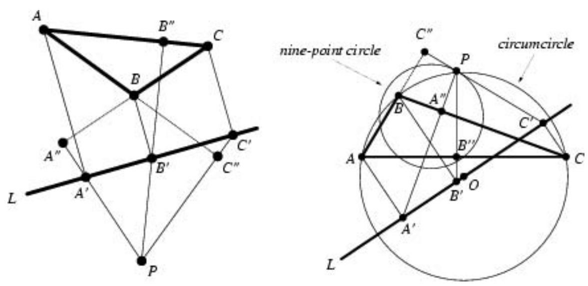
Orthonormal Transformation

ORTHOGONAL TRANSFORMATION

Orthonormal Vectors



UNIT VECTORS which are ORTHOGONAL are said to be orthonormal.

See also ORTHOGONAL VECTORS

Orthoplex

CROSS POLYTOPE

Orthopole

If perpendiculars A', B', and C' are dropped on any line L from the vertices of a TRIANGLE ΔABC, then the perpendiculars to the opposite sides from their FEET A'', B'', and C'' are CONCURRENT at a point P called the orthopole. The orthopole of a line lies on the SIMSON LINE which is PERPENDICULAR to it (Honsberger 1995, p. 130). If a line crosses the CIRCUMCIRCLE of a triangle, the SIMSON LINES of the points of intersection meet at the orthopole of the line. Also, the orthopole of a line through the CIRCUMCENTER O of a triangle ΔABC lies on that triangle's NINE-POINT CIRCLE (Honsberger 1995, p. 127).

If the line L is displaced PARALLEL to itself, the orthopole moves along a line PERPENDICULAR to L a distance equal to the displacement. If L is the SIMSON LINE of a point P, then P is called the POLE of L (Honsberger 1995, p. 128).

See also NINE-POINT CIRCLE, POLE (SIMSON LINE), RIGBY POINTS, SIMSON LINE

Orthosymmetric Matrix

PERSYMMETRIC MATRIX

Orthotomic

Given a source S and a curve γ, pick a point on γ and find its tangent T. Then the LOCUS of reflections of S about tangents T is the orthotomic curve (also known as the secondary CAUSTIC). The INVOLUTE of the orthotomic is the CAUSTIC. For a parametric curve $(f(t), g(t))$ with respect to the point (x_0, y_0), the orthotomic is

$$x = x_0 - \frac{2g'[f'(g - y_0) - g'(f - x_0)]}{f'^2 + g'^2}$$

$$y = y_0 + \frac{2f'[f'(g - y_0) - g'(f - x_0)]}{f'^2 + g'^2}$$

See also CAUSTIC, INVOLUTE

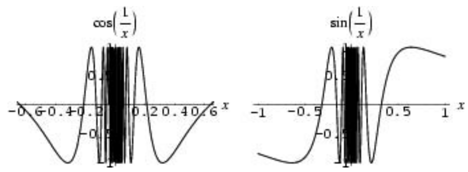
Coxeter, H. S. M. *Regular Polytopes, 3rd ed.* New York: Dover, pp. 122–123, 1973.

Osborne's Rule

The prescription that a TRIGONOMETRY identity can be converted to an analogous identity for HYPERBOLIC FUNCTIONS by expanding, exchanging trigonometric functions with their hyperbolic counterparts, and then flipping the sign of each term involving the product of two HYPERBOLIC SINES. For example, given the identity



$$\cos(x - y) = \cos x \cos y + \sin x \sin y,$$

Osborne's rule gives the corresponding identity

$$\cosh(x-y) = \cosh x \cosh y + \sinh x \sinh y.$$

See also HYPERBOLIC FUNCTIONS, TRIGONOMETRIC FUNCTIONS

Oscillation

The variation of a FUNCTION which exhibits SLOPE changes, also called the SALTUS of a function. A series may also oscillate, causing it not to converge.

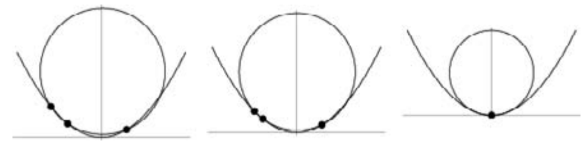
Oscillation Land

CAROTID-KUNDALINI FUNCTION

Osculating Circle

The CIRCLE which shares the same TANGENT as a curve at a given point. Given a plane curve with PARAMETRIC EQUATIONS $(f(t), g(t))$ and parameterized by a variable t, the RADIUS OF CURVATURE of the osculating circle is



$$\rho(t) = \frac{1}{|\kappa(t)|}, \tag{1}$$

where $\kappa(t)$ is the CURVATURE, and the center is

$$x = f - \frac{(f'^2 + g'^2)g'}{f'g'' - f''g'} \tag{2}$$

$$y = g + \frac{(f'^2 + g'^2)f'}{f'g'' - f''g'}. \tag{3}$$

Here, derivatives are taken with respect to the parameter t. Note that the centers of the osculating circles to a curve form the EVOLUTE to that curve.

In addition, let $C(t_1, t_2, t_3)$ denote the CIRCLE passing through three points on a curve $(f(t), g(t))$ with $t_1 < t_2 < t_3$. Then the osculating circle C is given by

$$C = \lim_{t_1, t_2, t_3 \to t} C(t_1, t_2, t_3) \tag{4}$$

(Gray 1997).

Gray, A. "Osculating Circles to Plane Curves." §5.6 in *Modern Differential Geometry of Curves and Surfaces with Mathematica, 2nd ed.* Boca Raton, FL: CRC Press, pp. 111–115, 1997.

Osculating Curves

An curve $y(x)$ is osculating to $f(x)$ at x_0 if it is TANGENT at x_0 and has the same CURVATURE there. Osculating curves therefore satisfy

$$y^{(k)}(x_0) = f^{(k)}(x_0)$$

for $k = 0,\ 1,\ 2$. The point of tangency is called a TACNODE.

One of simplest examples of a pairs of osculating curves is x^2 and $x^2 - x^4$, which osculate at the point $x_0 = 0$ since for $k = 0, 1, 2$, $y^{(k)}(0) = f^{(k)}(0)$ is equal to 0, 0, and 2.

Osculating Interpolation

HERMITE'S INTERPOLATING POLYNOMIAL

Osculating Plane

The PLANE spanned by the three points $\mathbf{x}(t)$, $\mathbf{x}(t+h_1)$, and $\mathbf{x}(t+h_2)$ on a curve as $h_1,\ h_2 \to 0$. Let $\mathbf{z}$ be a point

on the osculating plane, then

$$[(\mathbf{z}-\mathbf{x}),\ \mathbf{x}',\ \mathbf{x}'']=0,$$

where [**A**, **B**, **C**] denotes the SCALAR TRIPLE PRODUCT. The osculating plane passes through the tangent. The intersection of the osculating plane with the NORMAL PLANE is known as the PRINCIPAL NORMAL VECTOR. The VECTORS **T** and **N** (TANGENT VECTOR and NORMAL VECTOR) span the osculating plane.

See also NORMAL VECTOR, OSCULATING SPHERE, SCALAR TRIPLE PRODUCT, TANGENT VECTOR

Osculating Sphere

The center of any SPHERE which has a contact of (at least) first-order with a curve C at a point P lies in the normal plane to C at P. The center of any SPHERE which has a contact of (at least) second-order with C at point P, where the CURVATURE $\kappa > 0$, lies on the polar axis of C corresponding to P. All these SPHERES intersect the OSCULATING PLANE of C at P along a circle of curvature at P. The osculating sphere has center

$$\mathbf{a}=\mathbf{x}+\rho\hat{\mathbf{N}}+\frac{\dot{\rho}}{\tau}\ \hat{\mathbf{B}}$$

where $\hat{\mathbf{N}}$ is the unit NORMAL VECTOR, $\hat{\mathbf{B}}$ is the unit BINORMAL VECTOR, ρ is the RADIUS OF CURVATURE, and τ is the TORSION, and RADIUS

$$R=\sqrt{\rho^2+\left(\frac{\dot{\rho}}{\tau}\right)^2},$$

and has contact of (at least) third order with C.

Oval

An oval is a curve resembling a squashed CIRCLE but, unlike the ELLIPSE, without a precise mathematical definition. The word oval derived from the Latin word "ovus" for egg. Unlike ellipses, ovals sometimes have only a single axis of reflection symmetry (instead of two).

Ovals can be constructed with a COMPASS by joining together arcs of different radii such that the centers of the arcs lie on a line passing through the join point (Dixon 1991). Albrecht Dürer used this method to design a Roman letter font.

Overlapfree Word

N.B. A detailed online essay by S. Finch was the starting point for this entry.

A word is said to be overlapfree if it has no subwords OF THE FORM $xyxyx$. A SQUAREFREE WORD is overlapfree, and an overlapfree word is CUBEFREE. The number $t(n)$ of binary overlapfree words of length $n = 1, 2, ...$ are 2, 4, 6, 10, 14, 20, ... (Sloane's A007777). $t(n)$ satisfies

$$p \cdot n^{1.155} \leq t(n) \leq q \cdot n^{1.587} \quad (1)$$

for some constants p and q (Restivo and Selemi 1985, Kobayashi 1988). In addition, while

$$\lim_{n\to\infty} \frac{\ln t(n)}{\ln n} \quad (2)$$

does not exist,

$$1.155 < T_L < 1.276 < 1.332 < T_U < 1.587, \quad (3)$$

where

$$T_L \equiv \liminf_{n\to\infty} \frac{\ln t(n)}{\ln n} \quad (4)$$

$$T_U \equiv \limsup_{n\to\infty} \frac{\ln t(n)}{\ln n} \quad (5)$$

(Cassaigne 1993).

Padé Approximant

Approximants derived by expanding a function as a ratio of two POWER SERIES and determining both the NUMERATOR and DENOMINATOR COEFFICIENTS. Padé approximations are usually superior to TAYLOR EXPANSIONS when functions contain POLES, because the use of RATIONAL FUNCTIONS allows them to be well-represented.

The Padé approximant $R_{L/0}$ corresponds to the MACLAURIN SERIES. When it exists, the $R_{L/M} \equiv [L/M]$ Padé approximant to any POWER SERIES

$$A(x) = \sum_{j=0}^{\infty} a_j x^j \tag{1}$$

is unique. If $A(x)$ is a TRANSCENDENTAL FUNCTION, then the terms are given by the TAYLOR SERIES about x_0

$$a_n = \frac{1}{n!} A^{(n)}(x_0). \tag{2}$$

The COEFFICIENTS are found by setting

$$A(x) - \frac{P_L(x)}{Q_M(x)} = 0 \tag{3}$$

and equating COEFFICIENTS. $Q_M(x)$ can be multiplied by an arbitrary constant which will rescale the other COEFFICIENTS, so an addition constraint can be applied. The conventional normalization is

$$Q_M(0) = 1. \tag{4}$$

Expanding (3) gives

$$P_L(x) = p_0 + p_1 x + \ldots + p_L x^L \tag{5}$$

$$Q_M(x) = 1 + q_1 x + \ldots + p_M x^M. \tag{6}$$

These give the set of equations

$$a_0 = p_0 \tag{7}$$

$$a_1 + a_0 q_1 = p_1 \tag{8}$$

$$a_2 + a_1 q_1 + a_0 q_2 = p_2 \tag{9}$$

$$\vdots$$

$$a_L + a_{L-1} q_1 + \ldots + a_0 q_L = p_L \tag{10}$$

$$a_{L+1} + a_L q_1 + \ldots + a_{L-M+1} q_M = 0 \tag{11}$$

$$\vdots$$

$$q_{L+M} + a_{L+M-1} q_1 + \ldots + a_L q_M = 0, \tag{12}$$

where $a_n = 0$ for $n < 0$ and $q_j = 0$ for $j > M$. Solving these directly gives

$$[L/M] = \frac{\begin{vmatrix} a_{L-m+1} & a_{L-m+2} & \cdots & a_{L+1} \\ \vdots & \vdots & \ddots & \vdots \\ a_L & a_{L+1} & \cdots & a_{L+M} \\ \sum_{j=M}^{L} a_j - M^{x^j} & \sum_{j=M-1}^{L} a_{j-M+1} x^j & \cdots & \sum_{j=0}^{L} a_j x^j \end{vmatrix}}{\begin{vmatrix} a_{L-m+1} & a_{L-m+2} & \cdots & a_{L+1} \\ \vdots & \vdots & \ddots & \vdots \\ a_L & a_{L+1} & \cdots & a_{L+M} \\ x^M & x^{M-1} & \cdots & 1 \end{vmatrix}}, \tag{13}$$

where sums are replaced by a zero if the lower index exceeds the upper. Alternate forms are

$$[L/M] = \sum_{j=0}^{L-M} a_j x^j + x^{L-M+1}\mathbf{w}_{L/M}^{\mathrm{T}} \mathsf{W}_{L/M}^{-1}\mathbf{w}_{L/M}$$

$$= \sum_{j=0}^{L+n} a_j x^j + x^{L+n+1}\mathbf{w}_{(L+M)/M}^{\mathrm{T}} \mathsf{W}_{L/M}^{-1}\mathbf{w}_{(L+n)/M}$$

for

$$\mathsf{W}_{L/M} = \begin{bmatrix} a_{L-M+1} - x a_{L-M+2} & \cdots & a_L - x a_{L+1} \\ \vdots & \ddots & \vdots \\ a_L - x a_{L+1} & \cdots & a_{L+M-1} - x a_{L+M} \end{bmatrix} \quad (14)$$

$$\mathbf{w}_{L/M} = \begin{bmatrix} a_{L-M+1} \\ a_{L-M+2} \\ \vdots \\ a_L \end{bmatrix}, \quad (15)$$

and $0 \le n \le M$.

For example, the first few Padé approximants for e^x are

$$\exp_{0/0}(x) = 1$$
$$\exp_{0/1}(x) = \frac{1}{1-x}$$
$$\exp_{0/2}(x) = \frac{2}{2-2x+x^2}$$
$$\exp_{0/3}(x) = \frac{6}{6-6x+3x^2-x^3}$$
$$\exp_{1/0}(x) = 1+x$$
$$\exp_{1/1}(x) = \frac{2+x}{2-x}$$
$$\exp_{1/2}(x) = \frac{6+2x}{6-4x+x^2}$$
$$\exp_{1/3}(x) = \frac{24+6x}{24-18x+6x^2-x^3}$$
$$\exp_{2/0}(x) = \frac{2+2x+x^2}{2}$$
$$\exp_{2/1}(x) = \frac{6+4x+x^2}{6-2x}$$
$$\exp_{2/2}(x) = \frac{12+6x+x^2}{12-6x+x^2}$$
$$\exp_{2/3}(x) = \frac{60+24x+3x^2}{60-36x+9x^2-x^3}$$
$$\exp_{3/0}(x) = \frac{6+6x+3x^2+x^3}{6}$$
$$\exp_{3/1}(x) = \frac{24+18x+16x^2+x^3}{24-6x}$$
$$\exp_{3/2}(x) = \frac{60+36x+9x^2+x^3}{60-24x+3x^2}$$
$$\exp_{3/3}(x) = \frac{120+60x+12x^2+x^3}{120-60x+12x^2-x^3}.$$

Two-term identities include

$$\frac{P_{L+1}(x)}{Q_{M+1}(x)} - \frac{P'_L(x)}{Q'_M(x)} = \frac{C^2_{(L+1)/(M+1)}x^{L+M+1}}{Q_{M+1}(x)Q'_M(x)} \quad (16)$$

$$\frac{P_{L+1}(x)}{Q_M(x)} - \frac{P'_L(x)}{Q'_M(x)} = \frac{C_{(L+1)/M}C_{(L+1)/(M+1)}x^{L+M+1}}{Q_M(x)Q'_M(x)} \quad (17)$$

$$\frac{P_L(x)}{Q_{M+1}(x)} - \frac{P'_L(x)}{Q'_M(x)} = \frac{C_{L/(M+1)}C_{(L+1)/(M+1)}x^{L+M+1}}{Q_M(x)Q'_M(x)} \quad (18)$$

$$\frac{P_L(x)}{Q_{M+1}(x)} - \frac{P'_{L+1}(x)}{Q'_M} = \frac{C^2_{(L+1)/(M+1)}x^{L+M+2}}{Q_{M+1}Q'_M} \quad (19)$$

$$\frac{P_{L+1}}{Q_M(x)} - \frac{P'_{L-1}(x)}{Q'_M(x)} = \frac{C_{L/(M+1)}C_{(L+1)/M}x^{L+M} + C_{L/M}C_{(L+1)/(M+1)}x^{L+M+1}}{Q_M(x)Q'_M(x)} \quad (20)$$

$$\frac{P_L(x)}{Q_{M+1}(x)} - \frac{P'_L(x)}{Q'_{M-1}(x)} = \frac{C_{L/(M+1)}C_{(L+1)/M}x^{L+M} - C_{L/M}C_{(L+1)/(M+1)}x^{L+M+1}}{Q_{M+1}(x)Q'_{M-1}(x)}, \quad (21)$$

where C is the C-DETERMINANT. Three-term identities can be derived using the FROBENIUS TRIANGLE IDENTITIES (Baker 1975, p. 32).

A five-term identity is

$$S_{(L+1)/M}S_{(L-1)/M} - S_{L/(M+1)}S_{L/(M-1)} = S^2_{L/M}. \quad (22)$$

Cross ratio identities include

$$\frac{\left(R_{L/M} - R_{L/(M+1)}\right)\left(R_{(L+1)/M} - R_{(L+1)/(M+1)}\right)}{\left(R_{L/M} - R_{(L+1)/M}\right)\left(R_{L/(M+1)} - R_{(L+1)/(M+1)}\right)} = \frac{C_{L/(M+1)}C_{(L+2)/(M+1)}}{C_{(L+1)/M}C_{(L+1)/(M+2)}} \quad (23)$$

$$\frac{\left(R_{L/M} - R_{(L+1)/(M+1)}\right)\left(R_{(L+1)/M} - R_{L/(M+1)}\right)}{\left(R_{L/M} - R_{L/(M+1)}\right)\left(R_{(L+1)/M} - R_{(L+1)/(M+1)}\right)} = \frac{C^2_{(L+1)/(M+1)}x}{C_{L/(M+1)}C_{(L+2)/(M+1)}} \quad (24)$$

$$\frac{\left(R_{L/M} - R_{(L+1)/(M+1)}\right)\left(R_{(L+1)/M} - R_{L/(M+1)}\right)}{\left(R_{L/M} - R_{(L+1)/M}\right)\left(R_{L/(M+1)} - R_{(L+1)/(M+1)}\right)} = \frac{C^2_{(L+1)/(M+1)}x}{C_{(L+1)/M}C_{(L+1)/(M+2)}} \quad (25)$$

$$\frac{\left(R_{L/M} - R_{(L+1)/(M+1)}\right)\left(R_{L/(M+1)} - R_{(L+1)/M}\right)}{\left(R_{L/M} - -R_{L/(M+1)}\right)\left(R_{(L+1)/(M+1)} - R_{(L+1)/M}\right)}$$

$$= \frac{C_{(L+1)/M} C_{(L+1)/(M+1)} x}{C_{L/(M+1)} C_{(L+2)/M}} \quad (26)$$

$$\frac{\left(R_{L/M} - R_{(L-1)/(M+1)}\right)\left(R_{(L+1)/M} - R_{L/(M+1)}\right)}{\left(R_{L/M} - R_{(L+1)/M}\right)\left(R_{(L-1)/(M+1)} - R_{L/(M+1)}\right)}$$

$$= \frac{C_{L/(M+1)} C_{(L+1)/(M+1)} x}{C_{(L+1)/M} C_{L/(M+2)}}. \quad (27)$$

Padé Conjecture

If $P(z)$ is a POWER SERIES which is regular for $|z| \leq 1$ except for m POLES within this CIRCLE and except for $z = +1$, at which points the function is assumed continuous when only points $|z| \leq 1$ are considered, then at least a subsequence of the $[N, N]$ PADÉ APPROXIMANTS are uniformly bounded in the domain formed by removing the interiors of small circles with centers at these POLES and uniformly continuous at $z = +1$ for $|z| \leq 1$.

p-adic Absolute Value

P-ADIC NORM

p-adic Norm

Any NONZERO RATIONAL NUMBER x can be represented by

$$x = \frac{p^a r}{s}, \quad (1)$$

where p is a PRIME NUMBER, r and s are INTEGERS not DIVISIBLE by p, and a is a unique INTEGER. The p-adic norm of x is then defined by

$$|x|_p = p^{-a}. \quad (2)$$

Also define the p-adic value

$$|0|_p = 0. \quad (3)$$

As an example, consider the FRACTION

$$\tfrac{140}{297} = 2^2 \cdot 3^{-3} \cdot 5 \cdot 7 \cdot 11^{-1}. \quad (4)$$

It has p-adic absolute values given by

$$\left|\tfrac{140}{297}\right|_2 = \tfrac{1}{4} \quad (5)$$

$$\left|\tfrac{140}{297}\right|_3 = 27 \quad (6)$$

$$\left|\tfrac{140}{297}\right|_5 = \tfrac{1}{5} \quad (7)$$

$$\left|\tfrac{140}{297}\right|_7 = \tfrac{1}{7} \quad (8)$$

$$\left|\tfrac{140}{297}\right|_{11} = 11. \quad (9)$$

The p-adic norm of a nonzero RATIONAL NUMBER x can be implemented in *Mathematica* as follows.

```
PadicNorm[x_Integer,   p_Integer?PrimeQ]   :=
p^(-IntegerExponent[x, p])
  PadicNorm[x_Rational, p_Integer?PrimeQ]  :=
PadicNorm[Numerator[x],                    p]/
PadicNorm[Denominator[x], p]
```

The p-adic norm satisfies the relations

1. $|x|_p \geq 0$ for all x,
2. $|x|_p = 0$ IFF $x = 0$,
3. $|xy|_p = |x|_p |y|_p$ for all x and y,
4. $|x+y|_p \leq |x|_p + |y|_p$ for all x and y (the TRIANGLE INEQUALITY), and
5. $|x+y|_p \leq \max(|x|_p, |y|_p)$ for all x and y (the STRONG TRIANGLE INEQUALITY).

In the above, relation 4 follows trivially from relation 5, but relations 4 and 5 are relevant in the more general VALUATION THEORY.

The p-adic norm is the basis for the algebra of *P*-ADIC NUMBERS.

See also *P*-ADIC NUMBER

p-adic Number

A p-adic number is an extension of the FIELD of RATIONAL NUMBERS such that CONGRUENCES MODULO POWERS of a fixed PRIME p are related to proximity in the so called "p-adic metric."

Any NONZERO RATIONAL NUMBER x can be represented by

$$x = \frac{p^a r}{s}, \tag{1}$$

where p is a PRIME NUMBER, r and s are INTEGERS not DIVISIBLE by p, and a is a unique INTEGER. Then define the P-ADIC NORM of x by

$$|x|_p = p^{-a}. \tag{2}$$

Also define the p-adic norm

$$|0|_p = 0. \tag{3}$$

The p-adics were probably first introduced by Hensel (1897) in a paper which was concerned with the development of algebraic numbers in POWER SERIES. p-adic numbers were then generalized to VALUATIONS by Kürschák (1913). Hasse (1923) subsequently formulated the LOCAL-GLOBAL PRINCIPLE (now usually called the HASSE PRINCIPLE), which is one of the chief applications of LOCAL FIELD theory. Skolem's p-adic method, which is used in attacking certain DIOPHANTINE EQUATIONS, is another powerful application of p-adic numbers. Another application is the theorem that the HARMONIC NUMBERS H_n are never INTEGERS (except for H_1). A similar application is the proof of the VON STAUDT-CLAUSEN THEOREM using the p-adic valuation, although the technical details are somewhat difficult. Yet another application is provided by the MAHLER-LECH THEOREM.

Every RATIONAL x has an "essentially" unique p-adic expansion ("essentially" since zero terms can always be added at the beginning)

$$x = \sum_{j=m}^{\infty} a_j p^j, \tag{4}$$

with m an INTEGER, a_j the INTEGERS between 0 and $p-1$ inclusive, and where the sum is convergent with respect to p-adic valuation. If $x \neq 0$ and $a_m \neq 0$, then the expansion is unique. Burger and Struppeck (1996) show that for p a PRIME and n a POSITIVE INTEGER,

$$|n!|_p = p^{-(n-A_p(n))/(p-1)}, \tag{5}$$

where the p-adic expansion of n is

$$n = a_0 + a_1 p + a_2 p^2 + \ldots + a_L p^L, \tag{6}$$

and

$$A_p(n) = a_0 + a_1 + a_2 + \ldots + a_L. \tag{7}$$

For sufficiently large n,

$$|n!|_p \leq p^{-n/(2p-2)}. \tag{8}$$

The p-adic valuation on $\mathbb{Q}$ gives rise to the p-adic metric

$$d(x, y) = |x - y|_p, \tag{9}$$

which in turn gives rise to the p-adic topology. It can be shown that the rationals, together with the p-adic metric, do not form a COMPLETE METRIC SPACE. The completion of this space can therefore be constructed, and the set of p-adic numbers $\mathbb{Q}_p$ is defined to be this completed space.

Just as the REAL NUMBERS are the completion of the RATIONALS $\mathbb{Q}$ with respect to the usual absolute valuation $|x-y|$, the p-adic numbers are the completion of $\mathbb{Q}$ with respect to the p-adic valuation $|x-y|_p$. The p-adic numbers are useful in solving DIOPHANTINE EQUATIONS. For example, the equation $X^2 = 2$ can easily be shown to have no solutions in the field of 2-adic numbers (we simply take the valuation of both sides). Because the 2-adic numbers contain the rationals as a subset, we can immediately see that the equation has no solutions in the RATIONALS. So we have an immediate proof of the irrationality of $\sqrt{2}$.

This is a common argument that is used in solving these types of equations: in order to show that an equation has no solutions in $\mathbb{Q}$, we show that it has no solutions in an EXTENSION FIELD. For another example, consider $X^2 + 1 = 0$. This equation has no solutions in $\mathbb{Q}$ because it has no solutions in the reals $\mathbb{R}$, and $\mathbb{Q}$ is a subset of $\mathbb{R}$.

Now consider the converse. Suppose we have an equation that does have solutions in $\mathbb{R}$ and in all the $\mathbb{Q}_p$ for every PRIME p. Can we conclude that the equation has a solution in $\mathbb{Q}$? Unfortunately, in general, the answer is no, but there are classes of equations for which the answer is yes. Such equations are said to satisfy the HASSE PRINCIPLE.

Padovan Sequence

The INTEGER SEQUENCE defined by the RECURRENCE RELATION

$$P(n) = P(n-2) + P(n-3)$$

with the initial conditions $P(0) = P(1) = P(2) = 1$. The RECURRENCE RELATION can be solved explicitly, giving

$$P(n) = \frac{1 + r_1}{r_1^{n+2}(2 + 3r_1)} + \frac{1 + r_2}{r_2^{n+2}(2 + 3r_2)} + \frac{1 + r_3}{r_3^{n+2}(2 + 3r_3)},$$

where r_n is the nth root of

$$x^3 + x^2 - 1 = 0.$$

The first few terms are 1, 1, 2, 2, 3, 4, 5, 7, 9, 12, ... (Sloane's A000931).

The ratio $\lim_{n\to\infty} P(n)/P(n-1)$ is called the PLASTIC CONSTANT.

Painlevé Property

Following the work of Fuchs in classifying first-order ORDINARY DIFFERENTIAL EQUATIONS, Painlevé studied second-order ODEs OF THE FORM

$$\frac{d^2y}{dx^2} = F(y', y, x),$$

where F is ANALYTIC in x and rational in y and y'. Painlevé found 50 types whose only movable SINGULARITIES are ordinary POLES. This characteristic is known as the Painlevé property. Six of the transcendents define new transcendents known as PAINLEVÉ TRANSCENDENTS, and the remaining 44 can be integrated in terms of classical transcendents, quadratures, or the PAINLEVÉ TRANSCENDENTS.

See also PAINLEVÉ TRANSCENDENTS

Painlevé Transcendents

There are six Painlevé transcendents, corresponding to second-order ordinary differential equations whose only movable singularities are ordinary poles and which cannot be integrated in terms of other known functions or transcendents.

$$y'' = 6y^2 + x \tag{1}$$

$$y = 2y^3 + xy + \alpha \tag{2}$$

$$y'' = \frac{y'^2}{y} - \frac{y'}{x} + \frac{\alpha y^2 + \beta}{x} + \gamma y^3 + \frac{\delta}{y} \tag{3}$$

$$y'' = \frac{y'^2}{2y} + \frac{3}{2} y^3 + 4xy^2 + 2(x^2 - \alpha)y + \frac{\beta}{y} \tag{4}$$

$$y = \left(\frac{1}{2y} + \frac{1}{y-1}\right) y'^2 - \frac{y'}{x} + \frac{(y-1)^2}{x^2}\left(\alpha y + \frac{\beta}{y}\right) + \frac{\gamma y}{x} + \frac{\delta y(y+1)}{y-1} \tag{5}$$

$$y = \frac{1}{2}\left(\frac{1}{y} + \frac{1}{y-1} + \frac{1}{y-x}\right) y'^2 + \left(\frac{1}{x} + \frac{1}{x-1} + \frac{1}{y-x}\right) y' + \frac{y(y-1)(y-x)}{x^2(x-1)^2}\left[\alpha + \frac{\beta x}{y^2} + \frac{\gamma(x-1)}{(y-1)^2} + \frac{\delta x(x-1)}{(y-x)^2}\right] \tag{6}$$

(Painlevé 1906; Ince 1956, p. 345; Zwillinger 1997, pp. 125–126). All Painlevé transcendents have first integrals for special values of their parameters except (2). Five of the transcendents were found by Painlevé and his students; the sixth transcendent was found by Gambier and contains the other five as limiting cases (Garnier 1916ab; Ince 1956, p. 345).

Pair

A SET of two numbers or objects linked in some way is said to be a pair. The pair a and b is usually denoted (a, b), and is generally considered to be ordered. In certain circumstances, pairs are also called BROTHERS or TWINS.

See also AMICABLE PAIR, AUGMENTED AMICABLE PAIR, BROWN NUMBERS, FRIENDLY PAIR, HEXAD, HOMOGENEOUS NUMBERS, IMPULSE PAIR, IRREGULAR PAIR, LAX PAIR, LONG EXACT SEQUENCE OF A PAIR AXIOM, MONAD, ORDERED PAIR, PERKO PAIR, QUADRUPLET, QUASIAMICABLE PAIR, QUINTUPLET, REDUCED AMICABLE PAIR, SMITH BROTHERS, TRIAD, TRIPLET, TWIN PEAKS, TWIN PRIMES, TWINS, UNITARY AMICABLE PAIR, WILF-ZEILBERGER PAIR, ZIP-PAIR

Pair Sum

Given an AMICABLE PAIR (m, n), the quantity

$$\sigma(m)=\sigma(n)=s(m)+s(n)=m+n$$

is called the pair sum, where $\sigma(n)$ is the DIVISOR FUNCTION and $s(n)$ is the RESTRICTED DIVISOR FUNCTION.

See also AMICABLE PAIR

Paired t-Test

Given two paired sets X_i and Y_i of n measured values, the paired t-test determines if they differ from each other in a significant way. Let

$$\hat{X}_i=(X_i-\bar{X}_i)$$
$$\hat{Y}_i=(Y_i-\bar{Y}_i),$$

then define t by

$$t=(\bar{X}-\bar{Y})\sqrt{\frac{n(n-1)}{\sum_{i=1}^n(\hat{X}_i-\hat{Y}_i)^2}}.$$

This statistic has $n-1$ DEGREES OF FREEDOM.

A table of STUDENT'S T-DISTRIBUTION confidence intervals can be used to determine the significance level at which two distributions differ.

See also FISHER SIGN TEST, HYPOTHESIS TESTING, STUDENT'S T-DISTRIBUTION, WILCOXON SIGNED RANK TEST

Paley Class

The Paley class of a POSITIVE INTEGER $m\equiv 0 \pmod 4$ is defined as the set of all possible QUADRUPLES (k,e,q,n) where

$$m=2^e(q^n+1),$$

q is an ODD PRIME, and

$$k=\begin{cases}0 & \text{if } q=0\\ 1 & \text{if } q^n-3\equiv 0 \pmod 4\\ 2 & \text{if } q^n-1\equiv 0 \pmod 4\\ \text{undefined} & \text{otherwise.}\end{cases}$$

See also HADAMARD MATRIX, PALEY CONSTRUCTION

Paley Construction

HADAMARD MATRICES H_n can be constructed using FINITE FIELD $GF(p^m)$ when $p=4l-1$ and m is ODD. Pick a representation r RELATIVELY PRIME to p. Then by coloring white $\lfloor (p-1)/2 \rfloor$ (where $\lfloor x \rfloor$ is the FLOOR FUNCTION) distinct equally spaced RESIDUES mod p (r^0, r, r^2, ...; r^0, r^2, r^4, ...; etc.) *in addition to* 0, a HADAMARD MATRIX is obtained if the POWERS of r (mod p) run through $< \lfloor (p-1)/2 \rfloor$. For example,

$$n=12=11^1+1=2(5+1)=2^2(2+1)$$

is of this form with $p=11=4\times 3-1$ and $m=1$. Since $m=1$, we are dealing with GF(11), so pick $p=2$ and compute its RESIDUES (mod 11), which are

$$p^0\equiv 1$$
$$p^1\equiv 2$$
$$p^2\equiv 4$$
$$p^3\equiv 8$$
$$p^4\equiv 16\equiv 5$$
$$p^5\equiv 10$$
$$p^6\equiv 20\equiv 9$$
$$p^7\equiv 18\equiv 7$$
$$p^8\equiv 14\equiv 3$$
$$p^9\equiv 6$$
$$p^{10}\equiv 12\equiv 1.$$

Picking the first $\lfloor 11/2 \rfloor=5$ RESIDUES and adding 0 gives: 0, 1, 2, 4, 5, 8, which should then be colored in the MATRIX obtained by writing out the RESIDUES increasing to the left and up along the border (0

through $p-1$, followed by ∞), then adding horizontal and vertical coordinates to get the residue to place in each square.

$$\begin{bmatrix} \infty & \infty & \infty & \infty & \infty & \infty & \infty & \infty & \infty & \infty & \infty & \infty \\ 10 & 0 & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & \infty \\ 9 & 10 & 0 & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & \infty \\ 8 & 9 & 10 & 0 & 1 & 2 & 3 & 4 & 5 & 6 & 7 & \infty \\ 7 & 8 & 9 & 10 & 0 & 1 & 2 & 3 & 4 & 5 & 6 & \infty \\ 6 & 7 & 8 & 9 & 10 & 0 & 1 & 2 & 3 & 4 & 5 & \infty \\ 5 & 6 & 7 & 8 & 9 & 10 & 0 & 1 & 2 & 3 & 4 & \infty \\ 4 & 5 & 6 & 7 & 8 & 9 & 10 & 0 & 1 & 2 & 3 & \infty \\ 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 0 & 1 & 2 & \infty \\ 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 0 & 1 & \infty \\ 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 0 & \infty \\ 0 & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & \infty \end{bmatrix}$$

H_{16} can be trivially constructed from $\mathsf{H}_4 \otimes \mathsf{H}_4$. H_{20} cannot be built up from smaller MATRICES, so use $n = 20 = 19 + 1 = 2(3^2 + 1) = 2^2(2^2 + 1)$. Only the first form can be used, with $p = 19 = 4 \times 5 - 1$ and $m = 1$. We therefore use GF(19), and color 9 RESIDUES plus 0 white. H_{24} can be constructed from $\mathsf{H}_2 \otimes \mathsf{H}_{12}$.

Now consider a more complicated case. For $n = 28 = 3^3 + 1 = 2(13 + 1)$, the only form having $p = 4l - 1$ is the first, so use the GF(3^3) field. Take as the modulus the IRREDUCIBLE POLYNOMIAL $x^3 + 2x + 1$, written 1021. A four-digit number can always be written using only three digits, since $1000 - 1021 \equiv 0012$ and $2000 - 2012 \equiv 0021$. Now look at the moduli starting with 10, where each digit is considered separately. Then

$x^0 \equiv 1$	$x^1 \equiv 10$	$x^2 \equiv 100$
$x^3 \equiv 1000 \equiv 12$	$x^4 \equiv 120$	$x^5 \equiv 1200 \equiv 212$
$x^6 \equiv 2120 \equiv 111$	$x^7 \equiv 1100 \equiv 122$	$x^8 \equiv 1220 \equiv 202$
$x^9 \equiv 2020 \equiv 11$	$x^{10} \equiv 110$	$x^{11} \equiv 1100 \equiv 112$
$x^{12} \equiv 1120 \equiv 102$	$x^{13} \equiv 1020 \equiv 2$	$x^{14} \equiv 20$
$x^{15} \equiv 200$	$x^{16} \equiv 2000 \equiv 21$	$x^{17} \equiv 210$
$x^{18} \equiv 2100 \equiv 121$	$x^{19} \equiv 1210 \equiv 222$	$x^{20} \equiv 2220 \equiv 211$
$x^{21} \equiv 2110 \equiv 101$	$x^{22} \equiv 101 \equiv 22$	$x^{23} \equiv 220$
$x^{24} \equiv 2200 \equiv 221$	$x^{25} \equiv 2210 \equiv 201$	$x^{26} \equiv 2010 \equiv 1$

Taking the alternate terms gives white squares as 000, 001, 020, 021, 022, 100, 102, 110, 111, 120, 121, 202, 211, and 221.

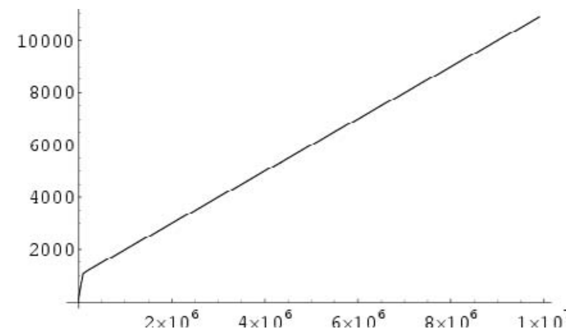
Paley's Theorem

Proved in 1933. If q is an ODD PRIME or $q = 0$ and n is any POSITIVE INTEGER, then there is a HADAMARD MATRIX of order

$$m = 2^e(q^n + 1),$$



where e is any POSITIVE INTEGER such that $m \equiv 0 \pmod 4$. If m is of this form, the matrix can be constructed with a PALEY CONSTRUCTION. If m is divisible by 4 but not OF THE FORM (1), the PALEY CLASS is undefined. However, HADAMARD MATRICES have been shown to exist for all $m \equiv 0 \pmod 4$ for $m < 428$.

See also HADAMARD MATRIX, PALEY CLASS, PALEY CONSTRUCTION

Palindrome Number

PALINDROMIC NUMBER

Palindromic Number

A symmetrical number which is written in some base b as $a_1 a_2 \cdots a_2 a_1$. The first few are 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 11, 22, 33, 44, 55, 66, 77, 88, 99, 101, 111, 121, ... (Sloane's A002113). The number of palindromic numbers less than a given number are illustrated in the plot above. The number of palindromic numbers less than 10, 10^2, 10^3, ... are 9, 18, 108, 198, 1098, 1998, 10998, ... (Sloane's A050250).

The sum of the reciprocals of the palindromic numbers converges to a constant ≈ 3.36977 (Rivera), where this value has been computed using all palindromic numbers $\leq 10^7$.

The first few n for which the PRONIC NUMBER P_n is palindromic are 1, 2, 16, 77, 538, 1621, ... (Sloane's A028336), and the first few palindromic numbers which are PRONIC are 2, 6, 272, 6006, 289982, ... (Sloane's A028337). The first few numbers whose squares are palindromic are 1, 2, 3, 11, 22, 26, ... (Sloane's A002778), and the first few palindromic squares are 1, 4, 9, 121, 484, 676, ... (Sloane's A002779).

There are no palindromic square n-digit numbers for $n = 2$, 4,8, 10, 14, 18, 20, 24, 30, ... (Sloane's A034822).

Palindromic Number Conjecture

Apply the 196-ALGORITHM, which consists of taking any POSITIVE INTEGER of two digits or more, reversing the digits, and adding to the original number. Now sum the two and repeat the procedure with the sum. Of the first 10,000 numbers, only 251 do not produce a PALINDROMIC NUMBER in ≤ 23 steps (Gardner 1979).

It was therefore conjectured that *all* numbers will eventually yield a PALINDROMIC NUMBER. However, the conjecture has been proven false for bases which are a POWER of 2, and seems to be false for base 10 as well. Among the first 100,000 numbers, 5,996 numbers apparently never generate a PALINDROMIC NUMBER (Gruenberger 1984). The first few are 196, 887, 1675, 7436, 13783, 52514, 94039, 187088, 1067869, 10755470, ... (Sloane's A006960).

It is conjectured, but not proven, that there are an infinite number of palindromic PRIMES. With the exception of 11, palindromic PRIMES must have an ODD number of digits.

Palindromic Prime

The first few palindromic PRIMES are 2, 3, 5, 7, 11, 101, 131, 151, 181, 191, 313, 353, 373, 383, 727, 757, 787, ... (Sloane's A002385; Beiler 1964, p. 228). The number of palindromic primes less than a given number are illustrated in the plot above. The number of palindromic numbers having $n = 1, 2, 3, \ldots$ digits are 4, 1, 15, 0, 93, 0, 668, 0, 5172, ... (Sloane's A016115; De Geest) and the total number of palindromic primes less than 10, 10^2, 10^3, ... are 4, 5, 20, 20, 113, 113, 781, ... (Sloane's A050251).

The sum of the reciprocals of the palindromic primes converges to ≈ 1.32398, where this value has been computed using all palindromic primes $\leq 10^{11}$ (M. Keith).

Palindromic primes formed from the reflected decimal expansion of PI include 3, 313,

$$31415926535897932384626433833462648323979853562951413,$$

... (Sloane's A039954).

The first few n such that both n and p_n are palindromic (where p_n is the nth prime) are given by 1, 2, 3, 4, 5, 8114118, ... (Sloane's A046942; Rivera), corresponding to p_n of 2, 3, 5, 7, 11, 143787341 (Sloane's A046941; Rivera).

Palindromic primes OF THE FORM

$$pp_n(x) = x^n + (x+1)^n$$

for $n = 2$ include 5, 181, 313, 3187813, ... (Sloane's A050239; De Geest, Rivera), which occur for $x = 1$, 9, 12, 1262, ... (Sloane's A050236; De Geest, Rivera), with no others for $n < 10^{20}$ and $x < 2 \times 10^{10}$ (De Geest). Dubner (1999) found

$$P = 10^35352 + 2049402 * 10^17673 + 1,$$

which, at 35,353 digits is believed to be the largest known prime that is not OF THE FORM, $ab^n \pm 1$.

CIRCLE DIVISION BY LINES

Pancake Sorting Problem

Assume that n numbered pancakes are stacked, and that a spatula can be used to reverse the order of the top k pancakes for $2 \leq k \leq n$. Then the pancake sorting problem asks how many such "prefix reversals" are sufficient to sort an arbitrary stack (Skiena 1990, p. 48).

Pandigital Number

A decimal INTEGER which contains each of the digits from 0 to 9 (and whose leading digit must be nonzero).

The first few pandigital numbers are 1023456789, 1023456798, 1023456879, 1023456897, 1023456978, ... (Sloane's A050278). A 10-digit pandigital number is always divisible by 9 since

$$\sum_{i=0}^{9} i = 45.$$

This passes the DIVISIBILITY TEST for 9 since $4+5=9$. The smallest pandigital primes must therefore have 11 digits (no two of which can be 0). The first few pandigital primes are therefore 10123457689, 10123465789, 10123465897, 10123485679, ... (Sloane's A050288).

If zeros are excluded, the first few "zeroless" pandigital numbers are 123456789, 123456798, 123456879, 123456897, 123456978, 123456987, ... (Sloane's A050289), and the first few zeroless pandigital primes are 1123465789, 1123465879, 1123468597, 1123469587, 1123478659, ... (Sloane's A050290).

The sum of the first 32423 (a PALINDROMIC NUMBER) consecutive PRIMES is 5897230146, which is pandigital (Honaker). No other PALINDROMIC NUMBER shares this property.

Numbers n that give zeroless pandigital numbers when the Fibonacci recurrence

$$a(n) = a(n-1) + a(n-2)$$

with $a(1)=1$ and $a(2)=n$ is applied are 718, 1790, 1993, 2061, 2259, 3888, 3960, 4004, 4396, 5093, 5832, 7031, 7310, 7712, 8039, 8955, 9236, ...

Panmagic Square

If *all* the DIAGONALS–including those obtained by "wrapping around" the edges–of a MAGIC SQUARE sum to the same MAGIC CONSTANT, the square is said to be a panmagic square (Kraitchik 1942, pp. 143 and 189–191). (Only the rows, columns, and *main diagonals* must sum to the same constant for the usual type of magic square.) The terms DIABOLIC SQUARE (Hunter and Madachy 1975, p. 24; Madachy 1979, p. 87), PANDIAGONAL SQUARE (Hunter and Madachy 1975, p. 24), and NASIK SQUARE (Madachy 1979, p. 87) are sometimes also used.

No panmagic squares exist of order 3 or any order $4k+2$ for k an INTEGER. The Siamese method for generating MAGIC SQUARES produces panmagic squares for orders $6k \pm 1$ with ordinary vector (2, 1) and break vector (1, -1).

1	15	24	8	17
23	7	16	5	14
20	4	13	22	6
12	21	10	19	3
9	18	2	11	25

The LO SHU is not panmagic, but it is an ASSOCIATIVE MAGIC SQUARE. Order four squares can be panmagic or ASSOCIATIVE, but not both. Order five squares are the smallest which can be both ASSOCIATIVE and panmagic, and 16 distinct ASSOCIATIVE panmagic squares exist, one of which is illustrated above (Gardner 1988).

The number of distinct panmagic squares of order 1, 2, ... are 1, 0, 0, 384, 3600, 0, ... (Sloane's A027567, Hunter and Madachy 1975). Panmagic squares are related to HYPERCUBES.

See also ASSOCIATIVE MAGIC SQUARE, HYPERCUBE, FRANKLIN MAGIC SQUARE, LO SHU, MAGIC SQUARE

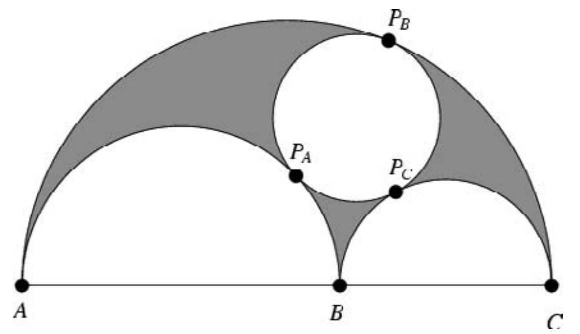
FOLDING, ORIGAMI

Pappus Chain

In the ARBELOS, construct a chain of TANGENT CIRCLES starting with the CIRCLE TANGENT to the two small interior semicircles and the large exterior one. This is called a Pappus chain (left figure).

In a Pappus chain, the distance from the center of the first INSCRIBED CIRCLE P_1 to the bottom line is twice the CIRCLE'S RADIUS, from the second CIRCLE P_2 is four times the RADIUS, and for the nth CIRCLE P_n is $2n$ times the RADIUS. Furthermore, the centers of the circles P_i lie on an ELLIPSE (right figure).



If $r \equiv AB/AC$, then the center and radius of the nth circle P_n in the Pappus chain are

$$x_n = \frac{r(1+r)}{2[n^2(1-r)^2+r]} \tag{1}$$

$$y_n = \frac{nr(1-r)}{n^2(1-r)^2+r} \tag{2}$$

$$r_n = \frac{(1-r)r}{2\left[n^2(1-r)^2+r\right]}. \tag{3}$$

This general result simplifies to $r_n = 1/(6+n^2)$ for $r = 2/3$ (Gardner 1979). Further special cases when $AC = 1 + AB$ are considered by Gaba (1940).

The positions of the points of tangency for the first circle are

$$x_A = \frac{r}{(1-r)^2} \tag{4}$$

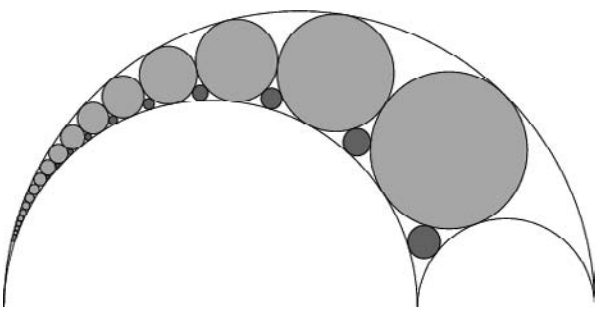
$$y_A = \frac{r(1-r)}{(1-r)^2} \tag{5}$$

$$x_B = \frac{r(1+r)}{1+r^2} \tag{6}$$

$$y_B = \frac{r(1-r)}{1+r^2} \tag{7}$$

$$x_C = \frac{r^2}{1-2r+2r^2} \tag{8}$$

$$y_C = \frac{r(1-r)}{1-2r+2r^2}. \tag{9}$$



The centers of the CIRCLES lie on an ELLIPSE, and the DIAMETER of the nth CIRCLE P_n is $(1/n)$th PERPENDICULAR distance to the base of the SEMICIRCLE. This result was known to Pappus, who referred to it as an ancient theorem (Hood 1961, Cadwell 1966, Gardner 1979, Bankoff 1981). The simplest proof is via INVERSIVE GEOMETRY. Eliminating n from the equations for x_n and y_n gives

$$4rx^2 - 2r(1+r)x + (1+r)^2 y^2 = 0 \quad (10)$$

$$4r\left[x - \tfrac{1}{4}(1+r)\right]^2 + (1+r^2)y^2 = \tfrac{1}{4}r(1+r)^2 \quad (11)$$

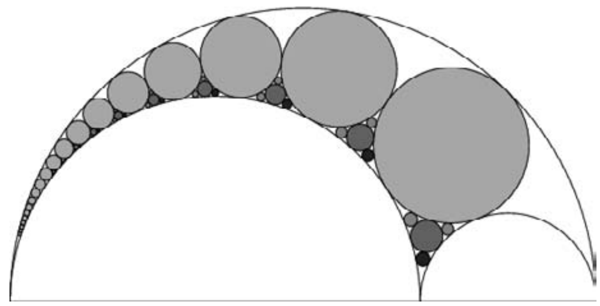
$$\left[\frac{x - \frac{1}{4}(1+r)}{\frac{1}{4}(1+r)}\right]^2 + \left(\frac{y}{\frac{1}{2}\sqrt{r}}\right)^2 = 1, \quad (12)$$

which is the equation of an ellipse with center $((1+r)/4,\ 0)$ and semimajor and semiminor axes $(1+r)/4$ and $\sqrt{r}/2$ respectively.

The circles T_n tangent to the first arbelos semicircle and adjacent Pappus circles P_{n-1} and P_n have positions and sizes

$$x'_n = \frac{r(7+r)}{2[4 + 4n(n-1)(1-r)^2 + r(r-1)]} \quad (13)$$

$$y'_n = \frac{2(2n-1)r(1-r)}{4 + 4n(n-1)(1-r)^2 + r(r-1)} \quad (14)$$



$$r'_n = \frac{r(1-r)}{2[4 + 4n(n-1)(1-r)^2 + r(r-1)]}. \quad (15)$$

A special case of this problem with $r = 1/2$ (giving equal circles forming the arbelos) was considered in a Japanese temple tablet (Sangaku) problem from 1788 in the Tokyo prefecture (Rothman 1998). In this case, the solution simplifies to

$$x'_n = \frac{15}{2(15 - 4n + 4n^2)} \quad (16)$$

$$y'_n = \frac{2(2n-1)}{15 - 4n + 4n^2} \quad (17)$$

$$r'_n = \frac{1}{2(15 - rn + 4n^2)}. \quad (18)$$

Furthermore, the positions and radii of the three tangent circles surrounding this circle can also be found analytically, and are given by

$$x_n^{(1)} = \frac{r(17+r)}{2\left[12 + 3n(3n-4)(1-r)^2 + r(4r-7)\right]} \quad (19)$$

$$y_n^{(1)} = \frac{3(3n-2)(1-r)r}{12 + 3n(3n-4)(1-r)^2 + r(4r-7)} \quad (20)$$

$$r_n^{(1)} = \frac{r(1-r)}{2\left[12 + 3n(3n-4)(1-r)^2 + r(4r-7)\right]} \quad (21)$$

$$x_n^{(2)} = \frac{r(17+r)}{2\left[9 + 3n(3n-2)(1-r)^2 - r(1-r)\right]} \quad (22)$$

$$y_n^{(2)} = \frac{3(3n-1)(1-r)r}{9 + 3n(3n-2)(1-r)^2 - r(1-r)} \quad (23)$$

$$r_n^{(2)} = \frac{r(1-r)}{2\left[9 + 3n(3n-2)(1-r)^2 - r(1-r)\right]} \quad (24)$$

$$x_n^{(3)} = \frac{r(17+7r)}{2\left[9 + 12n(n-1)(1-r)^2 + r(4r-1)\right]} \quad (25)$$

$$y_n^{(3)} = \frac{6(2n-1)(1-r)r}{9 + 12n(n-1)(1-r)^2 + r(4r-1)} \quad (26)$$

$$r_n^{(3)} = \frac{r(1-r)}{2[9 + 12n(n-1)(1-r)^2 + r(4r-1)]}. \quad (27)$$

If B divides AC in the GOLDEN RATIO ϕ, then the circles in the chain satisfy a number of other special properties (Bankoff 1955).

Pappus-Guldinus Theorem

PAPPUS'S CENTROID THEOREM

Pappus's Centroid Theorem

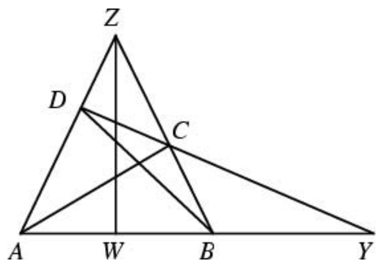
The SURFACE AREA S of a SURFACE OF REVOLUTION generated by the revolution of a curve about an external axis is equal to the product of the arc length s of the generating curve and the distance d_1 traveled by the curve's centroid $\bar{x}_1$,

$$S = sd_1 = 2\pi s\bar{x}_1.$$

Similarly, the VOLUME V of a SOLID OF REVOLUTION generated by the revolution of a lamina about an external axis is equal to the product of the area A of the lamina and the distance d_2 traveled by the lamina's centroid $\bar{x}_2$,

$$V = Ad_2 = 2\pi A\bar{x}_2.$$

The following table summarizes the surface areas and volumes calculated using Pappus's centroid theorem for various solids and surfaces of revolution.



SOLID	SECTION	s	$\bar{x}_1$	S	A	$\bar{x}_2$	V
CONE	RIGHT TRIANGLE	$\sqrt{r^2+h^2}$	$\frac{1}{2}r$	$\pi r\sqrt{r^2+h^2}$	$\frac{1}{2}hr$	$\frac{1}{3}hr$	$\frac{1}{3}\pi r^2$
CYLINDER	CIRCLE	h	$\frac{1}{2}r$	$2\pi rh$	hr	$\frac{1}{2}r$	$\pi r^2 h$
SPHERE	SEMI-CIRCLE	πr	$\frac{2r}{\pi}$	$4\pi r^2$	$\frac{1}{2}\pi r^2$	$\frac{4r}{3\pi}$	$\frac{4}{3}\pi r^3$

Parabola

The set of all points in the PLANE equidistant from a given LINE L (the DIRECTRIX) and a given point F not on the line (the FOCUS). The FOCAL PARAMETER (i.e., the distance between the directrix and focus) is therefore given by $p = 2a$, where a is the distance from the vertex to the directrix or focus.

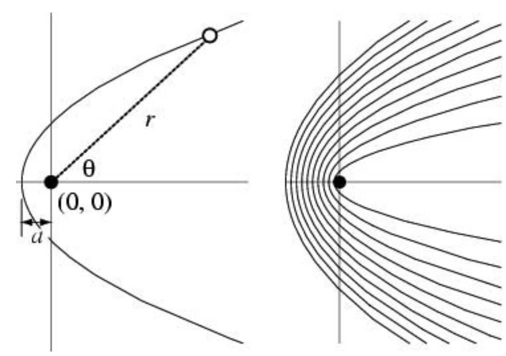
The parabola was studied by Menaechmus in an attempt to achieve CUBE DUPLICATION. Menaechmus solved the problem by finding the intersection of the two parabolas $x^2 = y$ and $y^2 = 2x$. Euclid wrote about the parabola, and it was given its present name by Apollonius. Pascal considered the parabola as a projection of a CIRCLE, and Galileo showed that projectiles falling under uniform gravity follow parabolic paths. Gregory and Newton considered the CATACAUSTIC properties of a parabola which bring parallel rays of light to a focus (MacTutor Archive), as illustrated above.

For a parabola opening to the right with vertex at (0, 0), the equation in CARTESIAN COORDINATES is

$$\sqrt{(x-a)^2 + y^2} = x + a \tag{1}$$

$$(x-a)^2 + y^2 = (x+a)^2 \tag{2}$$

$$x^2 - 2ax + a^2 + y^2 = x^2 + 2ax + a^2 \tag{3}$$



$$y^2 = 4ax. \tag{4}$$

The quantity $4a$ is known as the LATUS RECTUM. If the vertex is at (x_0, y_0) instead of (0, 0), the equation of the parabola is

$$(y - y_0)^2 = 4a(x - x_0). \tag{5}$$

If the parabola instead opens upwards, its equation is

$$x^2 = 4ay. \tag{6}$$

In POLAR COORDINATES, the equation of a parabola with parameter a and center (0, 0) is given by

$$r = -\frac{2a}{1 + \cos\theta} \tag{7}$$

(left figure). The equivalence with the Cartesian form can be seen by setting up a coordinate system $(x', y') = (x - a, y)$ and plugging in $r = \sqrt{x'^2 + y'^2}$ and $\theta = \tan^{-1}(y'/x')$ to obtain

$$\sqrt{(x-a)^2 + y^2} = -\frac{2a}{1 + \frac{x-a}{\sqrt{(x-a)^2 + y^2}}}. \tag{8}$$

Expanding and collecting terms,

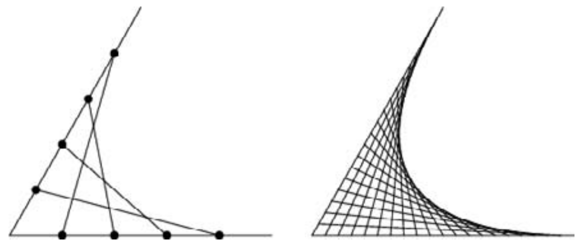
$$a + x + \sqrt{(a-x)^2 + y^2} = 0, \tag{9}$$

so solving for y^2 gives (4). A set of confocal parabolas is shown in the figure on the right.

In PEDAL COORDINATES with the PEDAL POINT at the FOCUS, the equation is

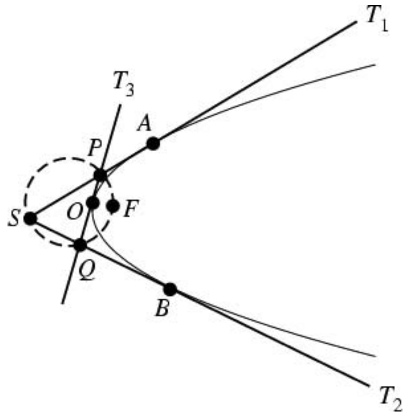
$$p^2 = ar. \tag{10}$$

The parametric equations for the parabola are



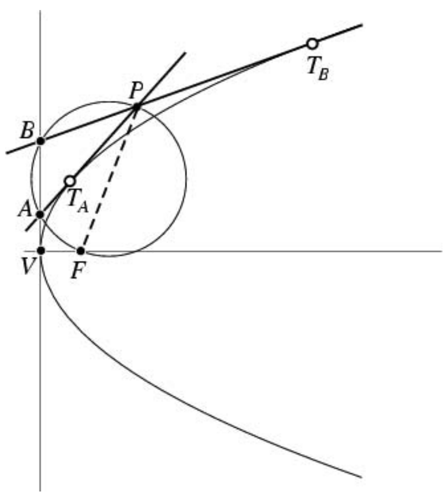
$$x = at^2 \tag{11}$$

$$y = 2at \tag{12}$$

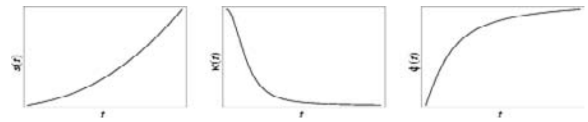


or

$$x = \frac{t^2}{4a} \tag{13}$$



$$y = t. \tag{14}$$



A parabola may be generated as the envelope of two concurrent line segments by connecting opposite points on the two lines (Wells 1991).

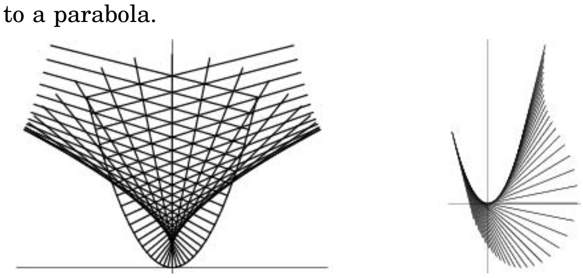
In the above figure, the lines SPA, SQB, and POQ are tangent to the parabola at points A, B, and O, respectively. Then $SP/PA = QO/OP = BQ/QS$ (Wells 1991). Moreover, the CIRCUMCIRCLE of ΔPQS passes through the FOCUS F (Honsberger 1995, p. 47). In addition, the foot of the perpendicular to a tangent to a parabola from the FOCUS always lies on the tangent at the vertex (Honsberger 1995, p. 48).

Given an arbitrary point P located "outside" a parabola, the tangent or tangents to the parabola through P can be constructed by drawing the CIRCLE having PF as a DIAMETER, where F is the FOCUS. Then locate the points A and B at which the circle cuts the VERTICAL TANGENT through V. The points T_A and T_B (which can collapse to a single point in the degenerate case) are then the points of tangency of the lines PA and PB and the parabola (Wells 1991).

The CURVATURE, ARC LENGTH, and TANGENTIAL ANGLE are

$$\kappa(t) = \frac{1}{2(1+t^2)^{3/2}} \tag{15}$$

$$s(t) = t\sqrt{1+t^2} + \sinh^{-1} t \tag{16}$$



$$\phi(t) = \tan^{-1} t. \tag{17}$$

The TANGENT VECTOR of the parabola is

$$x_T(t) = \frac{1}{\sqrt{1+t^2}} \tag{18}$$

$$y_T(t) = \frac{t}{\sqrt{1+t^2}}. \tag{19}$$

The plots below show the normal and tangent vectors to a parabola.

Parabola Caustic

The CAUSTIC of a PARABOLA with rays PERPENDICULAR to the axis of the PARABOLA is TSCHIRNHAUSEN CUBIC.

Parabola Evolute

Given a PARABOLA

$$y = x^2, \tag{1}$$

the parametric equations of the parabola are

$$x = t \tag{2}$$

$$y = t^2, \tag{3}$$

and the derivatives are

$$x' = 1 \tag{4}$$

$$x'' = 0 \tag{5}$$

$$y' = 2t \tag{6}$$

$$y'' = 2. \tag{7}$$

The RADIUS OF CURVATURE is therefore given by

$$R = \frac{(x'^2 + y'^2)^{3/2}}{x'y'' - x''y'} = \tfrac{1}{2}(1+4t^2)^{3/2}. \tag{8}$$

The TANGENT VECTOR is

$$\hat{\mathbf{T}} = \frac{1}{\sqrt{1+4t^2}} \begin{bmatrix} 1 \\ 2t \end{bmatrix}, \tag{9}$$

so the parametric equations of the evolute are

$$\xi = -4t^3 \tag{10}$$

$$\eta = \tfrac{1}{2} + 3t^2, \tag{11}$$

and

$$-\tfrac{1}{4}\,\xi = t^3 \tag{12}$$

$$\tfrac{1}{3}\left(\eta - \tfrac{1}{2}\right) = t^2 \tag{13}$$

$$\tfrac{1}{3}\left(\eta - \tfrac{1}{2}\right) = \left(-\tfrac{1}{4}\,\xi\right)^{2/3} \tag{14}$$

$$\tfrac{1}{3}\left(\eta - \tfrac{1}{2}\right) = \left(-\frac{2\xi}{8}\right)^{2/3} = \tfrac{1}{4}(2\xi)^{2/3}. \tag{15}$$

The EVOLUTE is therefore

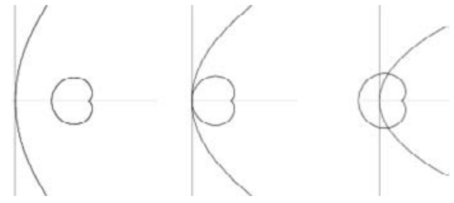
$$\eta = \tfrac{3}{4}(2\xi)^{2/3} + \tfrac{1}{2}. \tag{16}$$

This is known as NEILE'S PARABOLA and is a SEMICUBICAL PARABOLA. From a point above the evolute three normals can be drawn to the PARABOLA, while only one normal can be drawn to the PARABOLA from a point below the EVOLUTE.

See also NEILE'S PARABOLA, PARABOLA, SEMICUBICAL PARABOLA

Parabola Inverse Curve

The INVERSE CURVE for a PARABOLA given by

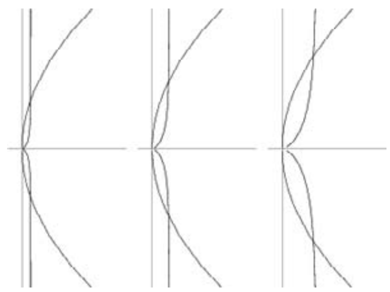


$$x = at^2 \tag{1}$$

$$y = 2at \tag{2}$$

with INVERSION CENTER (x_0, y_0) and INVERSION RADIUS k is

$$x = x_0 + \frac{k(at^2 - x_0)}{(at^2 + x_0)^2 + (2at - y_0)^2} \tag{3}$$

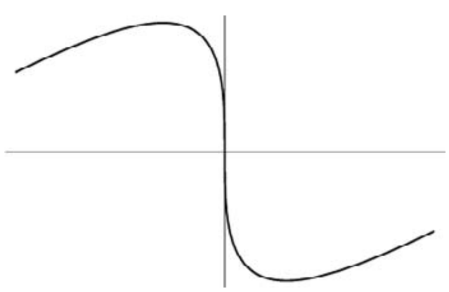


$$y = y_0 + \frac{k(2at - y_0)}{(at^2 + x_0)^2 + (2at - y_0)^2}. \tag{4}$$

For $(x_0, y_0) = (a, 0)$ at the FOCUS, the INVERSE CURVE is the CARDIOID

$$x = a + \frac{k(t^2 - 1)}{a(1+t^2)^2} \tag{5}$$

$$y = \frac{2kt}{a(1+t^2)^2}. \qquad (6)$$



For $(x_0,\ y_0) = (0,\ 0)$ at the VERTEX, the INVERSE CURVE is the CISSOID OF DIOCLES

$$x = \frac{k}{a(4+t^2)} \qquad (7)$$

$$y = \frac{2k}{at(4+t^2)}. \qquad (8)$$

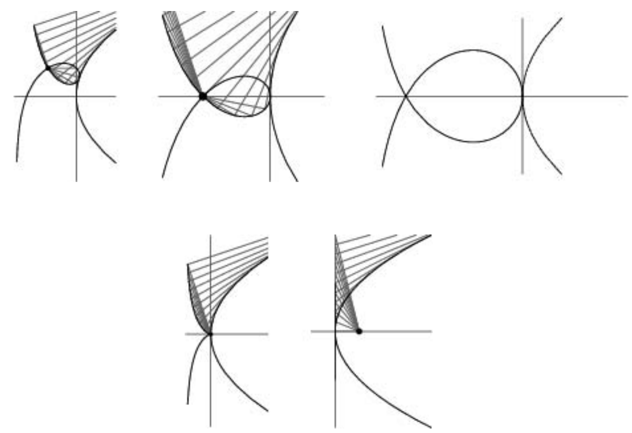
Parabola Involute

$$\frac{d\mathbf{r}}{dt} = \begin{bmatrix} 1 \\ 2t \end{bmatrix} \qquad (1)$$

$$\hat{\mathbf{T}} = \frac{1}{\sqrt{1+4t^2}} \begin{bmatrix} 1 \\ 2t \end{bmatrix} \qquad (2)$$

$$ds^2 = |d\mathbf{r}|^2 = (1+4t^2)\, dt^2 \qquad (3)$$

$$ds = \sqrt{1+4t^2}\, dt \qquad (4)$$



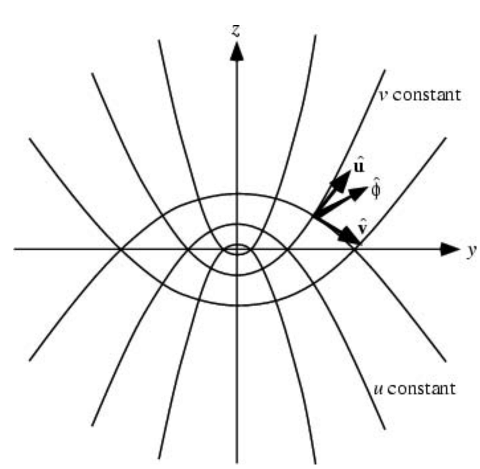
$$s = \int \sqrt{1+4t^2}\, dt = \tfrac{1}{2} t \sqrt{1+4t^2} + \tfrac{1}{4} \sinh^{-1}(2t), \qquad (5)$$

so the equation of the INVOLUTE is

$$\mathbf{r}_i = \mathbf{r} - s\hat{\mathbf{T}} = \begin{bmatrix} t \\ t^2 \end{bmatrix} - \frac{\frac{1}{2} t\sqrt{1+4t^2} + \frac{1}{4}\sinh^{-1}(2t)}{\sqrt{1+4t^2}} \begin{bmatrix} 1 \\ 2t \end{bmatrix}$$

$$= \frac{1}{2\sqrt{1+4t^2}} \begin{bmatrix} t - \frac{1}{2}\sinh^{-1}(2t) \\ -\sinh^{-1}(2t) \end{bmatrix}. \qquad (6)$$

Parabola Pedal Curve



On the DIRECTRIX, the PEDAL CURVE of a PARABOLA is a STROPHOID (top left). On the foot of the DIRECTRIX, it is a RIGHT STROPHOID (top middle). On reflection of the FOCUS in the DIRECTRIX, it is a MACLAURIN TRISECTRIX (top right). On the VERTEX, it is a CISSOID OF DIOCLES (bottom left). On the FOCUS, it is a straight line (bottom right; Hilbert and Cohn-Vossen 1999, pp. 26–27).

Parabolic Coordinates

A system of CURVILINEAR COORDINATES in which two sets of coordinate surfaces are obtained by revolving

the parabolas of PARABOLIC CYLINDRICAL COORDINATES about the x-AXIS, which is then relabeled the z-AXIS. There are several notational conventions. Whereas (u, v, θ) is used in this work, Arfken (1970) uses (ξ, η, φ).
The equations for the parabolic coordinates are

$$x = uv \cos \theta \tag{1}$$

$$y = uv \sin \theta \tag{2}$$

$$z = \tfrac{1}{2}(u^2 - v^2), \tag{3}$$

where $u \in [0, \infty)$, $v \in [0, \infty)$, and $\theta \in [0, 2\pi)$. To solve for u, v, and θ, examine

$$\begin{aligned} x^2 + y^2 + z^2 &= u^2v^2 + \tfrac{1}{4}(u^4 - 2u^2v^2 + v^4) \\ &= \tfrac{1}{4}(u^4 + 2u^2v^2 + v^4) \\ &= \tfrac{1}{4}(u^2 + v^2)^2, \end{aligned} \tag{4}$$

so

$$\sqrt{x^2 + y^2 + z^2} = \tfrac{1}{2}(u^2 + v^2) \tag{5}$$

and

$$\sqrt{x^2 + y^2 + z^2} + z = u^2 \tag{6}$$

$$\sqrt{x^2 + y^2 + z^2} - z = v^2. \tag{7}$$

We therefore have

$$u = \sqrt{\sqrt{x^2 + y^2 + z^2} + z} \tag{8}$$

$$v = \sqrt{\sqrt{x^2 + y^2 + z^2} - z} \tag{9}$$

$$\theta = \tan^{-1}\left(\frac{y}{x}\right). \tag{10}$$

The SCALE FACTORS are

$$h_u = \sqrt{u^2 + v^2} \tag{11}$$

$$h_v = \sqrt{u^2 + v^2} \tag{12}$$

$$h_\theta = uv. \tag{13}$$

The LINE ELEMENT is

$$ds^2 = (u^2 + v^2)(du^2 + dv^2) + u^2v^2\, d\theta^2, \tag{14}$$

and the VOLUME ELEMENT is

$$dV = uv(u^2 + v^2)\, du\, dv\, d\theta. \tag{15}$$

The LAPLACIAN is

$$\begin{aligned} \nabla^2 f &= \frac{1}{uv(u^2 + v^2)}\left[\frac{\partial}{\partial u}\left(uv\frac{\partial f}{\partial u}\right) + \frac{\partial}{\partial v}\left(uv\frac{\partial f}{\partial v}\right)\right] \\ &\quad + \frac{1}{u^2v^2}\frac{\partial^2 f}{\partial \theta^2} \\ &= \frac{1}{u^2 + v^2}\left[\frac{1}{u}\frac{\partial}{\partial u}\left(u\frac{\partial f}{\partial u}\right) + \frac{1}{v}\frac{\partial}{\partial v}\left(v\frac{\partial f}{\partial v}\right)\right] \\ &\quad + \frac{1}{u^2v^2}\frac{\partial^2 f}{\partial \theta^2} \\ &= \frac{1}{u^2 + v^2}\left(\frac{1}{u}\frac{\partial f}{\partial u} + \frac{\partial^2 f}{\partial u^2} + \frac{1}{v}\frac{\partial f}{\partial v} + \frac{\partial^2 f}{\partial v^2}\right) \\ &\quad + \frac{1}{u^2v^2}\frac{\partial^2 f}{\partial \theta^2}. \end{aligned} \tag{16}$$

The HELMHOLTZ DIFFERENTIAL EQUATION is SEPARABLE in parabolic coordinates.

Parabolic Cylinder Function

These functions are sometimes called WEBER FUNCTIONS. Whittaker and Watson (1990, p. 347) define the parabolic cylinder functions as solutions to the WEBER DIFFERENTIAL EQUATION

$$y''(z) + \left(n + \tfrac{1}{2} - \tfrac{1}{4} z^2\right) y(z) = 0. \quad (1)$$

The two independent solutions are given by $y = D_n(z)$ and $D_{-n-1}(ze^{i\pi/2})$, where

$$D_n(z) = 2^{n/2+1/4} z^{-1/2} W_{n/2+1/4,-1/4}\left(\tfrac{1}{2} z^2\right) \quad (2)$$

$$= \frac{\Gamma\left(\frac{1}{2}\right) 2^{n/2+1/4} z^{-1/2}}{\Gamma\left(\frac{1}{2} - \frac{1}{2} n\right)} \, {}_1F_1\left(\tfrac{1}{2} n + \tfrac{1}{4};\ -\tfrac{1}{4};\ \tfrac{1}{2} z^2\right)$$

$$+ \frac{\Gamma\left(-\frac{1}{2}\right) 2^{n/2+1/4} z^{-1/2}}{\Gamma\left(-\frac{1}{2} n\right)} \, {}_1F_1\left(\tfrac{1}{2} n + \tfrac{1}{4};\ \tfrac{1}{4};\ \tfrac{1}{2} z^2\right). \quad (3)$$

Here, $W_{a,\,b}(z)$ is a WHITTAKER FUNCTION and ${}_1F_1(a;\ b;\ z)$ is a CONFLUENT HYPERGEOMETRIC FUNCTIONS. The solutions can also be written as

$$y = e^{-z^2/4}\left[C_1 H_n\left(\frac{z}{\sqrt{2}}\right) + C_2 \, {}_1F_1\left(-\tfrac{1}{2} n;\ \tfrac{1}{2};\ \tfrac{1}{2} z^2\right), \quad (4)$$

where $H_n(x)$ is a HERMITE POLYNOMIAL.

Abramowitz and Stegun (1972, p. 686) define the parabolic cylinder functions as solutions to

$$y'' + (ax^2 + bx + c) = 0, \quad (5)$$

sometimes called the PARABOLIC CYLINDER DIFFERENTIAL EQUATION (Zwillinger 1995, p. 414; Zwillinger 1997, p. 126). This can be rewritten by COMPLETING THE SQUARE,

$$y'' + \left[a\left(x + \frac{b}{2a}\right)^2 - \frac{b^2}{4a} + c\right] y = 0. \quad (6)$$

Now letting

$$u = x + \frac{b}{2a} \quad (7)$$

$$du = dx \quad (8)$$

gives

$$\frac{d^2y}{du^2} + (au^2 + d)y = 0 \quad (9)$$

where

$$d \equiv \frac{b^2}{4a} + c. \quad (10)$$

Equation (5) has the two standard forms

$$y'' - \left(\tfrac{1}{4} x^2 + a\right) y = 0 \quad (11)$$

$$y'' + \left(\tfrac{1}{4} x^2 - a\right) y = 0. \quad (12)$$

For a general a, the EVEN and ODD solutions to (11) are

$$y_1(x) = e^{-x^2/4} \, {}_1f_1\left(\tfrac{1}{2} a + \tfrac{1}{4};\ \tfrac{1}{2};\ \tfrac{1}{2} x^2\right) \quad (13)$$

$$y_2(x) = xe^{-x^2/4} \, {}_1f_1\left(\tfrac{1}{2} a + \tfrac{3}{4};\ \tfrac{3}{2};\ \tfrac{1}{2} x^2\right), \quad (14)$$

where ${}_1F_1(a;\ b;\ z)$ is a CONFLUENT HYPERGEOMETRIC FUNCTION. If $y(a,\ x)$ is a solution to (11), then (12) has solutions

$$y\left(\pm ia,\ xe^{\mp i\pi/4}\right),\ y\left(\pm ia,\ -xe^{\mp i\pi/4}\right). \quad (15)$$

Abramowitz and Stegun (1972, p. 687) define standard solutions to (11) as

$$U(a,\ x) = \cos\left[\pi\left(\tfrac{1}{4} + \tfrac{1}{2} a\right)\right] Y_1 - \sin\left[\pi\left(\tfrac{1}{4} + \tfrac{1}{2} a\right)\right] Y_2 \quad (16)$$

$$V(a,\ x) = \frac{\sin\left[\pi\left(\frac{1}{4} + \frac{1}{2} a\right)\right] Y_1 + \cos\left[\pi\left(\frac{1}{4} + \frac{1}{2} a\right)\right] Y_2}{\Gamma\left(\frac{1}{2} - a\right)}, \quad (17)$$

where

$$Y_1 \equiv \frac{1}{\sqrt{\pi}} \frac{\Gamma\left(\frac{1}{4} - \frac{1}{2} a\right)}{2^{a/2+1/4}} \, y_1$$

$$= \frac{1}{\sqrt{\pi}} \frac{\Gamma\left(\frac{1}{4} - \frac{1}{2}a\right)}{2^{a/2+1/4}} e^{-x^2/4} \, {}_1F_1\left(\tfrac{1}{2}a + \tfrac{1}{4}; \tfrac{1}{2}; \tfrac{1}{2}x^2\right) \tag{18}$$

$$Y_2 \equiv \frac{1}{\sqrt{\pi}} \frac{\Gamma\left(\frac{3}{4} - \frac{1}{2}a\right)}{2^{a/2+1/4}} y_2$$

$$= \frac{1}{\sqrt{\pi}} \frac{\Gamma\left(\frac{3}{4} - \frac{1}{2}a\right)}{2^{a/2+1/4}} x e^{-x^2/4} \, {}_1F_1\left(\tfrac{1}{2}a + \tfrac{3}{4}; \tfrac{3}{2}; \tfrac{1}{2}x^2\right) \tag{19}$$

In terms of Whittaker and Watson's functions,

$$U(a, x) = D_{-a-1/2}(x) \tag{20}$$

$$V(a, x) = \frac{\Gamma\left(\frac{1}{2} + a\right)\left[\sin(\pi a) D_{-a-1/2}(x) + D_{-a-1/2}(-x)\right]}{\pi}. \tag{21}$$

For NONNEGATIVE INTEGER n, the solution D_n reduces to

$$D_n(x) = 2^{-n/2} e^{-x^2/4} H_n\left(\frac{x}{\sqrt{2}}\right) = e^{-x^2/4} \mathrm{He}_n(x), \tag{22}$$

where $H_n(x)$ is a HERMITE POLYNOMIAL and He^n is a modified HERMITE POLYNOMIAL.

The parabolic cylinder functions D_ν satisfy the RECURRENCE RELATIONS

$$D_{\nu+1}(z) - z D_\nu(z) + \nu D_{\nu-1}(z) = 0 \tag{23}$$

$$D'_\nu(z) + \tfrac{1}{2} z D_\nu(z) - \nu D_{\nu-1}(z) = 0. \tag{24}$$

The parabolic cylinder function for integral n can be defined in terms of an integral by

$$D_n(z) = \frac{1}{\pi} \int_0^\pi \sin(n\theta - z \sin\theta)\, d\theta \tag{25}$$

(Watson 1966, p. 308), which is similar to the ANGER FUNCTION. The result

$$\int_{-\infty}^{\infty} D_m(x) D_n(x)\, dx = \delta_{mn} n! \sqrt{2\pi}, \tag{26}$$

where δ_{ij} is the KRONECKER DELTA, can also be used to determine the COEFFICIENTS in the expansion

$$f(z) = \sum_{n=0}^{\infty} a_n D_n \tag{27}$$

as

$$a_n = \frac{1}{n!\sqrt{2\pi}} \int_{-\infty}^{\infty} D_n(t) f(t)\, dt. \tag{28}$$

For ν real,

$$\int_0^\infty [D_\nu(t)]^2\, dt$$

$$= \pi^{1/2} 2^{-3/2} \frac{\phi_0\left(\frac{1}{2} - \frac{1}{2}\nu\right) - \phi_0\left(-\frac{1}{2}\nu\right)}{\Gamma(-\nu)} \tag{29}$$

(Gradshteyn and Ryzhik 2000, p. 885, 7.711.3), where $\Gamma(z)$ is the GAMMA FUNCTION and $\phi_0(z)$ is the POLYGAMMA FUNCTION of order 0.

Parabolic Cylindrical Coordinates

A system of CURVILINEAR COORDINATES. There are several different conventions for the orientation and designation of these coordinates. Arfken (1970) de-

fines coordinates (ξ, η, z) such that

$$x = \xi\eta \tag{1}$$

$$y = \tfrac{1}{2}(\eta^2 - \xi^2) \tag{2}$$

$$z = z. \tag{3}$$

In this work, following Morse and Feshbach (1953), the coordinates (u, v, z) are used instead. In this convention, the traces of the coordinate surfaces of the xy-PLANE are confocal PARABOLAS with a common axis. The u curves open into the NEGATIVE X-AXIS; the v curves open into the POSITIVE X-AXIS. The u and v curves intersect along the Y-AXIS.

$$x = \tfrac{1}{2}(u^2 - v^2) \tag{4}$$

$$y = uv \tag{5}$$

$$z = z, \tag{6}$$

where $u \in [0, \infty)$, $v \in [0, \infty)$, and $z \in (-\infty, \infty)$. The SCALE FACTORS are

$$h_1 = \sqrt{u^2 + v^2} \tag{7}$$

$$h_2 = \sqrt{u^2 + v^2} \tag{8}$$

$$h_3 = 1. \tag{9}$$

LAPLACE'S EQUATION is

$$\nabla^2 f = \frac{1}{u^2 + v^2}\left(\frac{\partial^2 f}{\partial u^2} + \frac{\partial^2 f}{\partial v^2}\right) + \frac{\partial^2 f}{\partial z^2}. \tag{10}$$

The HELMHOLTZ DIFFERENTIAL EQUATION is SEPARABLE in parabolic cylindrical coordinates.

Parabolic Geometry

EUCLIDEAN GEOMETRY

Parabolic Horn Cyclide

A PARABOLIC CYCLIDE formed by INVERSION of a HORN TORUS when the INVERSION SPHERE is tangent to the TORUS.

See also CYCLIDE, INVERSION, INVERSION SPHERE, PARABOLIC RING CYCLIDE, PARABOLIC SPINDLE CYCLIDE

Parabolic Partial Differential Equation

A PARTIAL DIFFERENTIAL EQUATION of second-order, i.e., one OF THE FORM

$$Au_{xx} + 2Bu_{xy} + Cu_{yy} + Du_x + Eu_y + F = 0, \tag{1}$$

is called parabolic if the MATRIX

$$\mathsf{Z} \equiv \begin{bmatrix} A & B \\ B & C \end{bmatrix} \tag{2}$$

satisfies $\det(\mathsf{Z}) = 0$. The HEAT CONDUCTION EQUATION and other diffusion equations are examples. Initial-boundary conditions are used to give

$$u(x, t) = g(x, t) \quad \text{for } x \in \partial\Omega,\ t > 0 \tag{3}$$

$$u(x, 0) = v(x) \quad \text{for } x \in \Omega, \tag{4}$$

where

$$u_{xx} = f(u_x, u_y, u, x, y) \tag{5}$$

holds in Ω.

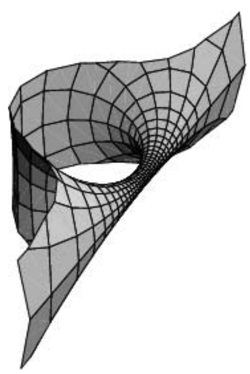
Parabolic Point

A point $\mathbf{p}$ on a REGULAR SURFACE $M \in \mathbb{R}^3$ is said to be parabolic if the GAUSSIAN CURVATURE $K(\mathbf{p}) = 0$ but $S(\mathbf{p}) \neq 0$ (where S is the SHAPE OPERATOR), or equiva-



lently, exactly one of the PRINCIPAL CURVATURES κ_1 and κ_2 is 0.

See also ANTICLASTIC, ELLIPTIC POINT, GAUSSIAN CURVATURE, HYPERBOLIC POINT, PLANAR POINT, SYNCLASTIC

References

Parabolic Ring Cyclide

A PARABOLIC CYCLIDE formed by INVERSION of a RING TORUS when the INVERSION SPHERE is tangent to the TORUS.

See also CYCLIDE, INVERSION, INVERSION SPHERE, PARABOLIC HORN CYCLIDE, PARABOLIC SPINDLE CYCLIDE

Parabolic Rotation

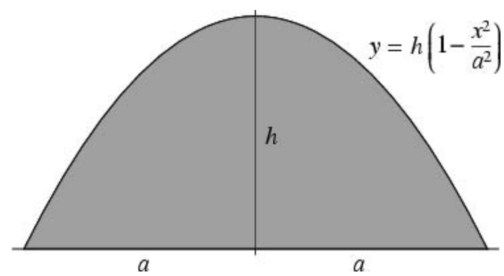
The MAP

$$x' = x + 1 \quad (1)$$

$$y' = 2x + y + 1, \quad (2)$$

which leaves the PARABOLA

$$x'^2 - y' = (x+1)^2 - (2x + y + 1) = x^2 - y \quad (3)$$



invariant.

See also PARABOLA, ROTATION

Parabolic Rule

SIMPSON'S RULE

Parabolic Segment

The ARC LENGTH of the parabolic segment

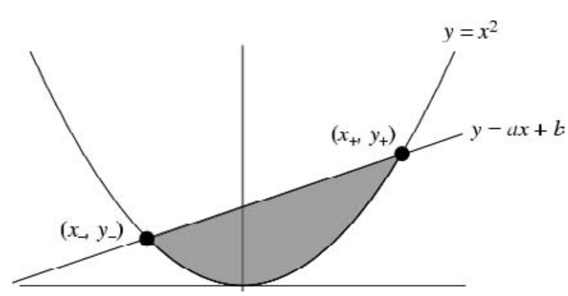
$$y = h\left(1 - \frac{x^2}{a^2}\right) \quad (1)$$

illustrated above is given by

$$s = \int_{-a}^{a} \sqrt{1 + y'^2}\, dx = 2\int_0^a \sqrt{1 + y'^2}\, dx \quad (2)$$

$$= \tfrac{1}{2}\sqrt{a^2 + 4h^2} + \frac{a^2}{4h} \ln\left(\frac{2h + \sqrt{a^2 + 4h^2}}{a}\right), \quad (3)$$

and the AREA is given by



$$A = \int_{-a}^{a} = h\left(1 - \frac{x^2}{a^2}\right) dx = \tfrac{4}{3} ah \quad (4)$$

(Kern and Bland 1948, p. 4). The weighted mean of y is

$$\langle y \rangle = \mathrm{int}_{-a}^{a} \int_0^{h(1 - x^2/a^2)} y\, dx\, dy = \tfrac{8}{15} ah^2, \quad (5)$$

so the CENTROID is then given by

$$\bar{y} = \frac{\langle y \rangle}{A} = \tfrac{2}{5} h. \quad (6)$$

The AREA of the cut-off parabolic segment contained between the curves

$$y = x^2 \quad (7)$$

$$y = ax + b \quad (8)$$

can be found by eliminating y,

$$x^2 - ax - b = 0, \quad (9)$$

so the points of intersection are

$$x_{\pm} = \tfrac{1}{2}\left(a \pm \sqrt{a^2+4b}\right), \tag{10}$$

with corresponding y-coordinates $y_{\pm} = x_{\pm}^2$. The AREA is therefore given by

$$A = \int_{a-\sqrt{a^2+4b}}^{a+\sqrt{a^2+4b}} \left[(ax+b) - x^2\right]\, dx \tag{11}$$

$$= \tfrac{1}{6}(a^2+4b)\sqrt{a^2+4b} = \tfrac{1}{6}(a^2+4b)^{3/2}. \tag{12}$$

The maximum AREA of a TRIANGLE inscribed in this segment will have two of its VERTICES at the intersections (x_-, y_-) and (x_+, y_+), and the third at a point (x^*, y^*) to be determined. From the general equation for a triangle, the AREA of the inscribed triangle is given by the DETERMINANT equation

$$A_\Delta = \begin{vmatrix} x^- & y^- & 1 \\ x^+ & y^+ & 1 \\ x^* & y^* & 1 \end{vmatrix}. \tag{13}$$

Plugging in and using $y_* = x_*^2$ gives

$$A_\Delta = \tfrac{1}{2}[b + (a - x^*)x^*]\sqrt{a^2+4b}. \tag{14}$$

To find the maximum AREA, differentiable with respect to x^* and set to 0 to obtain

$$\frac{\partial A_\Delta}{\partial x_*} = \tfrac{1}{2}(a - 2x^*)\sqrt{a^2+4b} = 0, \tag{15}$$

so

$$x_* = \tfrac{1}{2}a. \tag{16}$$

Plugging (16) into (14) then gives

$$A = \tfrac{1}{8}(a^2+4b)^{3/2}. \tag{17}$$

This leads to the result known to Archimedes in the third century BC , namely

$$\frac{A}{A_\Delta} = \frac{\frac{1}{6}}{\frac{1}{8}} = \frac{4}{3}. \tag{18}$$

Parabolic-Cylinder Coordinates

PARABOLIC CYLINDRICAL COORDINATES

Paraboloid

The SURFACE OF REVOLUTION of the PARABOLA which is the shape used in the reflectors of automobile headlights (Steinhaus 1983, p. 242; Hilbert and Cohn-Vossen 1999). It is a QUADRATIC SURFACE which can be specified by the Cartesian equation

$$z = b(x^2 + y^2). \tag{1}$$

The paraboloid which has radius a at height h is then given parametrically by

$$x(u, v) = a\sqrt{u/h}\cos v \tag{2}$$

$$y(u, v) = a\sqrt{u/h}\sin v \tag{3}$$

$$z(u, v) = u, \tag{4}$$

where $u \geq 0$, $v \in [0, 2\pi)$.

The coefficients of the FIRST FUNDAMENTAL FORM are given by

$$E = 1 + \frac{a^2}{4hu} \tag{5}$$

$$F = 0 \tag{6}$$

$$G = \frac{a^2 u}{h} \tag{7}$$

and the SECOND FUNDAMENTAL FORM coefficients are

$$e = \frac{a^2}{2u\sqrt{a^4 + 4a^2hu}} \tag{8}$$

$$f = 0 \tag{9}$$

$$g = \frac{2a^2u}{\sqrt{a^4 + 4a^2hu}} \tag{10}$$

The AREA ELEMENT is then

$$dS = \frac{\sqrt{a^4 + 4a^2hu}}{2h}\, du \wedge dv, \tag{11}$$

giving SURFACE AREA

$$S = \int_0^{2\pi}\int_0^h dS = \frac{\pi a}{6h^2}\left[\left(a^2 + 4h^2\right)^{3/2} - a^3\right]. \tag{12}$$

The GAUSSIAN CURVATURE is given by

$$K = \frac{4h^2}{\left(a^2 + 4hu\right)^2}, \tag{13}$$

and the MEAN CURVATURE

$$H = \frac{2h(a^2 + 2hu)}{(a^2 + 4hu)\sqrt{a^4 + 4a^2hu}}. \tag{14}$$

The VOLUME of the paraboloid of height h is then

$$V = \pi\int_0^h \frac{a^2 z}{h}\, dz = \tfrac{1}{2}\pi a^2 h. \tag{15}$$

The weighted mean of z over the paraboloid is

$$\langle z\rangle = \pi\int_0^h \frac{a^2 z}{h} z\, dz = \tfrac{1}{3}\pi a^2 h^2. \tag{16}$$

The CENTROID is then given by

$$\bar{z} = \frac{\langle z\rangle}{V} = \tfrac{2}{3}h \tag{17}$$

(Beyer 1987).

Paraboloid Geodesic

A GEODESIC on a PARABOLOID has differential parameters defined by

$$P \equiv \left(\frac{\partial x}{\partial u}\right)^2 + \left(\frac{\partial y}{\partial u}\right)^2 + \left(\frac{\partial z}{\partial u}\right)^2$$

$$= 1 + \frac{\cos^2 v}{4u} + \frac{\sin^2 v}{4u} = 1 + \frac{1}{4u} \tag{1}$$

$$Q \equiv \frac{\partial^2 x}{\partial u\,\partial v} + \frac{\partial^2 y}{\partial u\,\partial v} + \frac{\partial^2 z}{\partial u\,\partial v}$$

$$= 0 + u\cos^2 v + u\sin^2 v = u \tag{2}$$

$$R \equiv 0 - \frac{\sin v}{2\sqrt{u}} + \frac{\cos v}{2\sqrt{u}} = \frac{1}{2\sqrt{u}}(\cos v - \sin v). \tag{3}$$

The GEODESIC is then given by solving the EULER-LAGRANGE DIFFERENTIAL EQUATION

$$\frac{\frac{\partial P}{\partial v}+2v'\frac{\partial Q}{\partial v}+v'^2\frac{\partial R}{\partial v}}{2\sqrt{P+2Qv'+Rv'^2}}-\frac{d}{du}\left(\frac{Q+Rv'}{\sqrt{P+2Qv'+Rv'^2}}\right)=0. \quad (4)$$

As given by Weinstock (1974), the solution simplifies to

$$u-c^2=u(1+4c^2)\times\sin^2\left\{v-2c\ln\left[k\left(2\sqrt{u-c^2}+\sqrt{4u+1}\right)\right]\right\}. \quad (5)$$

CONFOCAL PARABOLOIDAL COORDINATES

Paracompact Space

A paracompact space is a HAUSDORFF SPACE such that every open COVER has a LOCALLY FINITE open REFINEMENT. Paracompactness is a very common property that TOPOLOGICAL SPACES satisfy. Paracompactness is similar to the compactness property, but generalized for slightly "bigger" SPACES. All MANIFOLDS (e.g, second countable and Hausdorff) are paracompact.

See also HAUSDORFF SPACE, LOCALLY FINITE SPACE, MANIFOLD, TOPOLOGICAL SPACE

Paracycle

ASTROID

Paradox

A statement which appears self-contradictory or contrary to expectations, also known as an ANTINOMY. Curry (1977, p. 5) uses the term PSEUDOPARADOX to describe an apparent paradox for which, however, there is no underlying actual contradiction. Bertrand Russell classified known logical paradoxes into seven categories.

Ball and Coxeter (1987) give several examples of geometrical paradoxes.

See also ALLAIS PARADOX, ARISTOTLE'S WHEEL PARADOX, ARROW'S PARADOX, BANACH-TARSKI PARADOX, BARBER PARADOX, BERNOULLI'S PARADOX, BERRY PARADOX, BERTRAND'S PARADOX, BUCHOWSKI PARADOX, BURALI-FORTI PARADOX, CANTOR'S PARADOX, CATALOGUE PARADOX, COASTLINE PARADOX, COIN PARADOX, ELEVATOR PARADOX, EPIMENIDES PARADOX, EUBULIDES PARADOX, GRELLING'S PARADOX, HAUSDORFF PARADOX, HEMPEL'S PARADOX, HETEROLOGICAL PARADOX, HYPERGAME, LEONARDO'S PARADOX, LIAR'S PARADOX, LOGICAL PARADOX, POTATO PARADOX, PSEUDOPARADOX, RICHARD'S PARADOX, RUSSELL'S PARADOX, SAINT PETERSBURG PARADOX, SIEGEL'S PARADOX, SIMPSON'S PARADOX, SKOLEM PARADOX, SMARANDACHE PARADOX, SOCRATES' PARADOX, SORITES PARADOX, THOMPSON LAMP PARADOX, UNEXPECTED HANGING PARADOX, ZEEMAN'S PARADOX, ZENO'S PARADOXES

Parallel

Two lines in 2-dimensional EUCLIDEAN SPACE are said to be parallel if they do not intersect. In 3-dimensional EUCLIDEAN SPACE, parallel lines not only fail to intersect, but also maintain a constant separation between points closest to each other on the two lines. (Lines in 3-space which are not parallel but do not intersect are called SKEW LINES.)

In a NON-EUCLIDEAN GEOMETRY, the concept of parallelism must be modified from its intuitive meaning. This is accomplished by changing the so-called PARALLEL POSTULATE. While this has counterintuitive results, the geometries so defined are still completely self-consistent.

In a TRIANGLE ΔABC, a MEDIAN BM_B bisects all segments parallel to a given side AC (Honsberger 1995, p. 87).

Parallel Curves

Parallel curves, frequently called "offset curves" in computer graphics applications, are curves which are displaced from a base curve by a constant offset, either positive or negative, in the direction of the curve's normal. The two branches of the parallel curve a distance k away from a parametrically represented base curve $(f(t), g(t))$ are

$$x = f \pm \frac{kg'}{\sqrt{f'^2 + g'^2}}$$

$$y = g \mp \frac{kf'}{\sqrt{f'^2 + g'^2}},$$

where $f' = df/dt$ and $g' = dg/dt$. The above figure shows curves parallel to a CIRCLE, ELLIPSE, and 3-

petalled ROSE, where the base curves are indicated in red.

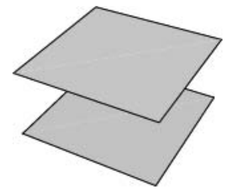
Parallel Lines

Two lines in 2-dimensional EUCLIDEAN SPACE are said to be parallel if they do not intersect.



In 3-dimensional EUCLIDEAN SPACE, parallel lines not only fail to intersect, but also maintain a constant separation between points closest to each other on the two lines. Therefore, parallel lines in 3-space lie in a single PLANE (Kern and Blank 1948, p. 9). Lines in 3-space which are not parallel but do not intersect are called SKEW LINES.

Parallel Postulate

Portions of this entry contributed by MATTHEW SZUDZIK

Given any straight line and a point not on it, there "exists one and only one straight line which passes" through that point and never intersects the first line, no matter how far they are extended. This statement is equivalent to the fifth of EUCLID'S POSTULATES, which Euclid himself avoided using until proposition 29 in the *ELEMENTS*. For centuries, many mathematicians believed that this statement was not a true postulate, but rather a theorem which could be derived from the first four of EUCLID'S POSTULATES. (That part of geometry which could be derived using only postulates 1–4 came to be known as ABSOLUTE GEOMETRY.)

Over the years, many purported proofs of the parallel postulate were published. However, none were correct, including the 28 "proofs" G. S. Klügel analyzed in his dissertation of 1763 (Hofstadter 1989). The main motivation for all of this effort was that Euclid's parallel postulate did not seem as "intuitive" as the other axioms, but it was needed to prove important results. John Wallis proposed a new axiom that implied the parallel postulate and was also intuitively appealing. His "axiom" states that any triangle can be made bigger or smaller without distorting its proportions or angles (Greenberg 1994, pp. 152–153). However, Wallis's axiom never caught on.

In 1823, Janos Bolyai and Lobachevsky independently realized that entirely self-consistent "NON-EUCLIDEAN GEOMETRIES" could be created in which the parallel postulate *did not hold.* (Gauss had also discovered but suppressed the existence of non-Euclidean geometries.)

As stated above, the parallel postulate describes the type of geometry now known as PARABOLIC GEOMETRY. If, however, the phrase "exists one and only one straight line which passes" is replaced by "exist no line which passes," or "exist at least two lines which pass," the postulate describes equally valid (though less intuitive) types of geometries known as ELLIPTIC and HYPERBOLIC GEOMETRIES, respectively.

The parallel postulate is equivalent to the EQUIDISTANCE POSTULATE, PLAYFAIR'S AXIOM, PROCLUS' AXIOM, the TRIANGLE POSTULATE, and the PYTHAGOREAN THEOREM. There is also a single parallel axiom in HILBERT'S AXIOMS which is equivalent to Euclid's parallel postulate.

S. Brodie has shown that the parallel postulate is equivalent to the PYTHAGOREAN THEOREM.

Parallelepiped

In 3-D, a parallelepiped is a PRISM whose faces are all PARALLELOGRAMS. The volume of a 3-D parallelepiped is given by the SCALAR TRIPLE PRODUCT

$$V_{\text{parallelepiped}} = |\mathbf{A} \cdot (\mathbf{B} \times \mathbf{C})| = |\mathbf{C} \cdot (\mathbf{A} \times \mathbf{B})| = |\mathbf{B} \cdot (\mathbf{C} \times \mathbf{A})|.$$

In n-D, a parallelepiped is the POLYTOPE spanned by n VECTORS $\mathbf{v}_1, ..., \mathbf{v}_n$ in a VECTOR SPACE over the reals,

$$\text{span}(\mathbf{v}_1, \ldots, \mathbf{v}_n) = t_1\mathbf{v}_1 + \ldots + t_n\mathbf{v}_n,$$

where $t_i \in [0, 1]$ for $i = 1, ..., n$. In the usual interpretation, the VECTOR SPACE is taken as EUCLIDEAN SPACE, and the CONTENT of this parallelepiped is given by

$$\text{abs}(\det(\mathbf{v}_1, \ldots, \mathbf{v}_n)),$$

where the sign of the determinant is taken to be the "orientation" of the "oriented volume" of the parallelepiped.

Given k vectors $v_1, ..., v_k$ in n-dimensional space, their CONVEX HULL (along with the ZERO VECTOR)

$$\left\{ \sum t_i v_i \middle| 0 \leq t_i \leq 1 \right\} \quad (1)$$

is called a parallelepiped, generalizing the notion of a parallelogram, or rather its interior, in the plane. If the number of vectors is equal to the dimension, then

$$\mathsf{A} = (v_1 \ldots v_k) \quad (2)$$

is a SQUARE MATRIX, and the volume of the parallelepiped is given by $|\det \mathsf{A}|$, where the columns of A are given by the vectors v. More generally, a parallelepiped has k dimensional volume given by $|\det \mathsf{A}^T A|^{1/2}$.

When the vectors are TANGENT VECTORS, then the parallelepiped represents an infinitesimal k-dimensional VOLUME ELEMENT. Integrating this volume can give formulas for the volumes of k-dimensional objects in n-dimensional space. More intrinsically, the parallelepiped corresponds to a DECOMPOSABLE element of the EXTERIOR ALGEBRA $\Lambda^k \mathbb{R}^n$.

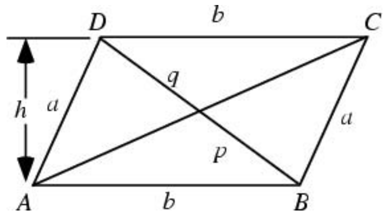
Parallelism

ANGLE OF PARALLELISM

Parallelizable



A HYPERSPHERE $\mathbb{S}^n$ is parallelizable if there exist n cuts containing linearly independent tangent vectors. There exist only three parallelizable spheres: $\mathbb{S}^1$, $\mathbb{S}^2$, and $\mathbb{S}^7$ (Adams 1962, Le Lionnais 1983).

Parallelogram

A QUADRILATERAL with opposite sides parallel (and therefore opposite angles equal). A quadrilateral with equal sides is called a RHOMBUS, and a parallelogram whose ANGLES are all RIGHT ANGLES is called a RECTANGLE. The DIAGONALS of a parallelogram bisect each other (Casey 1888, p. 2).

A parallelogram of base b and height h has AREA

$$A = bh = ab \sin A = ab \sin B. \qquad (1)$$

The height of a parallelogram is

$$h = a \sin A = a \sin B, \qquad (2)$$

and the DIAGONALS p and q are

$$p = \sqrt{a^2 + b^2 - 2ab \cos A} \qquad (3)$$

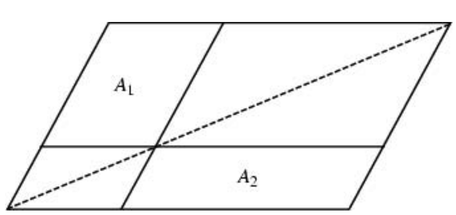
$$q = \sqrt{a^2 + b^2 - 2ab \cos B} \qquad (4)$$

$$= \sqrt{a^2 + b^2 + 2ab \cos A} \qquad (5)$$

(Beyer 1987).

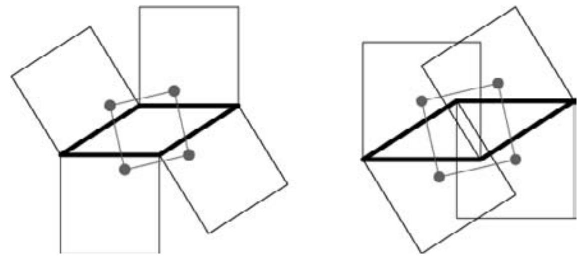
The sides a, b, c, d and diagonals p, q of a parallelogram satisfy

$$p^2 + q^2 = a^2 + b^2 + c^2 + d^2 \qquad (6)$$



(Casey 1888, p. 22).

The AREA of the parallelogram with sides formed by the VECTORS (a, c) and (b, d) is



$$A = \det\left(\begin{bmatrix} a & b \\ c & d \end{bmatrix}\right) = |ad - bc|. \qquad (7)$$

Given a parallelogram P with area $A(P)$ and linear transformation T, the AREA of $T(P)$ is

$$A(T(P)) = \begin{vmatrix} a & b \\ c & d \end{vmatrix} A(P). \qquad (8)$$

As shown by Euclid, if lines parallel to the sides are drawn through any point on a diagonal of a parallelogram, then the parallelograms not containing segments of that diagonal are equal in AREA (and conversely), so in the above figure, $A_1 = A_2$ (Johnson 1929).

The centers of four SQUARES erected either internally or externally on the sides of a parallelograms are the vertices of a SQUARE (Yaglom 1962, pp. 96–97; Coxeter and Greitzer 1967, p. 84).

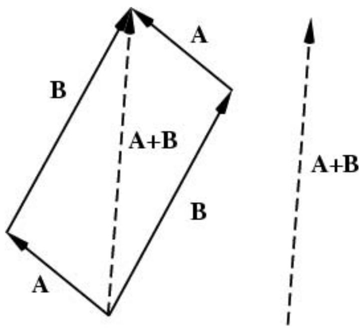
Parallelogram Illusion

In the above figure, the sides a and b have the same length, appearances to the contrary.



In the related illusion illustrated above, the interior

lines appear to be of different lengths, despite the fact that they are the same (Wells 1991).

References

Wells, D. *The Penguin Dictionary of Curious and Interesting Geometry.* London: Penguin, pp. 86–87, 1991.

Parallelogram Law

The parallelogram law gives the rule for VECTOR ADDITION of vectors **A** and **B**. The sum **A**+**B** of the vectors is obtained by placing them head to tail and drawing the vector from the free tail to the free head. Let $|\cdot|$ denote the NORM of a quantity. Then the quantities x and y are said to satisfy the parallelogram law if

$$\|x+y\|^2+\|x-y\|^2=2\|x\|^2+2\|y\|^2.$$

If the NORM is defined as $|f|=\sqrt{\langle f|f\rangle}$ (the so-called L2-NORM), then the law will always hold.

Coxeter, H. S. M. *Regular Polytopes, 3rd ed.* New York: Dover, p. 29, 1973.

Parallelotope

Move a point Π_0 along a LINE from an initial point to a final point. It traces out a LINE SEGMENT Π_1. When Π_1 is translated from an initial position to a final position, it traces out a PARALLELOGRAM Π_2. When Π_2 is translated, it traces out a PARALLELEPIPED Π_3. The generalization of Π_n to n-D is then called a parallelotope. Π_n has 2^n vertices and

$$N_k=2^{n-k}\binom{n}{k}$$

Π_ks, where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT and $k=0$, 1, ..., n (Coxeter 1973). These are also the coefficients of $(x+2)^n$.

Paralogic Triangles

At the points where a line cuts the sides of a TRIANGLE $\Delta A_1A_2A_3$, perpendiculars to the sides are drawn, forming a TRIANGLE $\Delta B_1B_2B_3$ similar to the given TRIANGLE. The two triangles are also in perspective. One point of intersection of their CIRCUMCIRCLES is the SIMILITUDE CENTER, and the other is the PERSPECTIVE CENTER. The CIRCUMCIRCLES meet ORTHOGONALLY.

See also CIRCUMCIRCLE, ORTHOGONAL CIRCLES, PERSPECTIVE CENTER, SIMILITUDE CENTER

Parameter

A parameter m used in ELLIPTIC INTEGRALS defined to be $m\equiv k^2$, where k is the MODULUS. An ELLIPTIC INTEGRAL is written $I(\phi|m)$ when the parameter is used. The complementary parameter is defined by

$$m'\equiv 1-m, \quad (1)$$

where m is the parameter. Let q be the NOME, k the MODULUS, and $m\equiv k^2$ the PARAMETER. Then

$$q(m)=e^{-\pi K'(m)/K(m)} \quad (2)$$

where $K(m)$ is the complete ELLIPTIC INTEGRAL OF THE FIRST KIND. Then the inverse of $q(m)$ is given by

$$m(q)=\frac{\vartheta_2^4(q)}{\vartheta_3^4(q)}, \quad (3)$$

where ϑ_i is a JACOBI THETA FUNCTION.

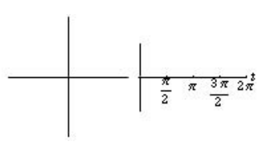
Parameter (Quadric)

The number θ in the quadric

$$\frac{x^2}{a^2+\theta}+\frac{y^2}{b^2+\theta}+\frac{z^2}{c^2+\theta}=1$$

is called the parameter.



See also Quadric

Parameterization

The specification of a curve, surface, etc., by means of one or more variables which are allowed to take on values in a given specified range.

See also Isothermal Parameterization, Parametric Equations, Regular Parameterization, Reparameterization, Surface Parameterization

Parametric Equations

Parametric equations are a set of equations that express a set of quantities as explicit functions of a number of independent variables, known as "parameters." For example, while the equation of a circle in Cartesian coordinates can be given by $r^2=x^2+y^2$, one set of parametric equations for the circle are given by

$$x=r\cos t$$

$$y=r\sin t,$$

illustrated above. Note that parametric representations are generally nonunique, so the same quantities may be expressed by a number of different parameterizations. A single parameter is usually represented with the parameter t, while the symbols u and v are commonly used for parametric equations in two parameters.

Parametric equations provide a convenient way to represent curves and surfaces, as implemented, for example, in the *Mathematica* commands `ParametricPlot[{x, y}, {t, t1, t2}]` and `ParametricPlot3D[{x, y, z}, {u, u1, u2}, {v, v1, v2}]`.

Parametric Latitude

An auxiliary latitude also called the reduced latitude and denoted η or θ. It gives the latitude on a sphere of radius a for which the parallel has the same radius as the parallel of geodetic latitude ϕ and the ellipsoid through a given point. It is given by

$$\eta=\tan^{-1}\left(\sqrt{1-e^2}\tan\phi\right).$$

In series form,

$$\eta=\phi-e_1\sin(2\phi)+\tfrac{1}{2}e_1^2\sin(4\phi)-\tfrac{1}{3}e_1^3\sin(6\phi)+\ldots,$$

where

$$e_1\equiv\frac{1-\sqrt{1-e^2}}{1+\sqrt{1-e^2}}.$$

Parametric Test

A statistical test in which assumptions are made about the underlying distribution of observed data.

Parametrization

Parameterization

Parenthesis

One of the symbols (or) used to denote grouping. Parentheses have a great many specialized meanings in mathematics. A few of these are described below.

1. Parentheses are used in mathematical expressions to denote modifications to normal order of

operations (precedence rules). In an expression like $(3+5)\times 7$, the part of the expression within the parentheses, $(3+5)=8$, is evaluated first, and then this result is used in the rest of the expression. Nested parentheses work similarly, since parts of expressions within parentheses are also considered expressions. Parentheses are also used in this manner to clarify order of operations in confusing or abnormally large expressions.

2. A parenthesis can be used to denote an open end of an INTERVAL. For example, [0, 5) denotes the HALF-OPEN INTERVAL which includes all real numbers from 0 to 5 except 5 itself.

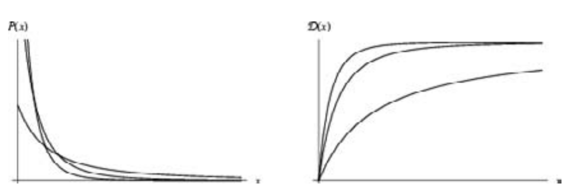
3. Parentheses are used to enclose the variables of a FUNCTION in the form $f(x)$, which means that values of the function f are dependent upon the values of x.

4. Large parentheses around two numbers, one above the other, denotes a BINOMIAL COEFFICIENT $\binom{n}{k}$.

5. Parentheses around a set of two or more numbers, as in (a, b, c), denote an n-tuple of numbers that are linked in some special way.

6. Large parentheses around an array of numbers, e.g., $\begin{pmatrix} a & b \\ c & d \end{pmatrix}$ indicate a MATRIX. (However, in this work, the symbol $\begin{bmatrix} a & b \\ c & d \end{bmatrix}$ is used instead.)

7. Parentheses may also be used to denote the GREATEST COMMON DIVISOR, e.g., $(54, 21)\equiv \mathrm{GCD}(54, 21)=3$.



8. Parenthesis are used to denote a CONGRUENCE, as in $a\equiv d \pmod{m}$.

Pareto Distribution

The distribution with probability density function and distribution function

$$P(x)=\frac{ab^a}{x^{a+1}} \tag{1}$$

$$D(x)=1-\left(\frac{b}{x}\right)^a \tag{2}$$

defined over the interval $x\geq b$. The RAW MOMENTS are

$$\mu'_1=\frac{ab}{a-1} \tag{3}$$

$$\mu'_2=\frac{ab^2}{a-2} \tag{4}$$

$$\mu'_3=\frac{ab^3}{a-3} \tag{5}$$

$$\mu'_4=\frac{ab^4}{a-4} \tag{6}$$

and the CENTRAL MOMENTS are

$$\mu_2=\frac{ab^2}{(a-1)^2(a-2)} \tag{7}$$

$$\mu_3=\frac{2a(a+1)b^3}{(a-1)^3(a-2)(a-3)} \tag{8}$$

$$\mu_4=\frac{3a(3a^3+a+2)b^4}{(a-1)^4(a-2)(a-3)(a-4)} \tag{9}$$

Giving MEAN, VARIANCE, SKEWNESS, and KURTOSIS

$$\mu=\frac{ab}{a-1} \tag{10}$$

$$\sigma^2=\frac{ab^2}{(a-1)^2(a-2)} \tag{11}$$

$$\gamma_1=\sqrt{\frac{a-2}{a}}\frac{2(a+1)}{a-3} \tag{12}$$

$$\gamma_2=\frac{6(a^3+a^2-6a-2)}{a(a-3)(a-4)}. \tag{13}$$

Parity

The parity of an integer is its attribute of being EVEN or ODD. Thus, it can be said that 6 and 14 have the same parity (since both are EVEN), whereas 7 and 12 have opposite parity (since 7 is ODD and 12 is EVEN).

More specifically, the parity of an integer n can be defined as the sum of the bits in BINARY representation, computed modulo 2. The parities of the first few integers (starting with 0) are therefore 0, 1, 1, 0, 1, 0, 0, 1, 1, 0, 0, ... (Sloane's A010060), summarized in the following table.

N	Binary	Parity	*N*	Binary	Parity
1	1	1	11	1011	1
2	10	1	12	1100	0
3	11	0	13	1101	1
4	100	1	14	1110	1
5	101	0	15	1111	0
6	110	0	16	10000	1
7	111	1	17	10001	0
8	1000	1	18	10010	0
9	1001	0	19	10011	1
10	1010	0	20	10100	0

The parity function obeys the sum identity

$$\sum_{k=0}^{2^{n+1}-1} (-1)^{P(k)}(k+r)^n = 0$$

for any n. For example, for $n=2$ and $r=0$,

$$1-4-9+16-25+36+49-64=0.$$

The constant generated by the sequence of parity digits $0.011010011\ldots_2$ is called the THUE-MORSE CONSTANT.

Parrondo's Paradox

Two losing gambling games can be set up so that when they are played one after the other, they become winning. There are many ways to construct such scenarios, the simplest of which uses three biased coins (Harmer and Abbott 1999).
